1. **Graphical User Interface (GUI)** .............................................................................. 1

   1.1. **GUI Components** .......................................................................................... 1

       1.1.1. **The Menu Bar** .................................................................................... 2

       1.1.2. **Toolbars** ............................................................................................. 3

           1.1.2.1. **The Mode Toolbar** ....................................................................... 3

           1.1.2.2. **The Standard Toolbar** .................................................................. 4

           1.1.2.3. **The Graphics Toolbar** ................................................................... 4

           1.1.2.4. **The Objects Toolbar** ..................................................................... 5

       1.1.3. **The Navigation Pane** ............................................................................. 6

       1.1.4. **Task Pages** .......................................................................................... 8

       1.1.5. **The Console** ......................................................................................... 8

       1.1.6. **Dialog Boxes** ....................................................................................... 9

           1.1.6.1. **Input Controls** ................................................................................. 10

               1.1.6.1.1. **Tabs** ....................................................................................... 10

               1.1.6.1.2. **Buttons** .................................................................................. 11

               1.1.6.1.3. **Check Boxes** ............................................................................ 11

               1.1.6.1.4. **Radio Buttons** ......................................................................... 11

               1.1.6.1.5. **Text Entry Boxes** ..................................................................... 11

               1.1.6.1.6. **Integer Number Entry Boxes** .................................................. 11

               1.1.6.1.7. **Real Number Entry Boxes** ....................................................... 12

               1.1.6.1.8. **Single-Selection Lists** ................................................................. 12

               1.1.6.1.9. **Multiple-Selection Lists** .............................................................. 12

               1.1.6.1.10. **Drop-Down Lists** ..................................................................... 13

               1.1.6.1.11. **Scales** ...................................................................................... 13

           1.1.6.2. **Types of Dialog Boxes** ....................................................................... 14

               1.1.6.2.1. **Information Dialog Boxes** ........................................................... 14

               1.1.6.2.2. **Warning Dialog Boxes** ............................................................... 14

               1.1.6.2.3. **Error Dialog Boxes** ................................................................... 14

               1.1.6.2.4. **The Working Dialog Box** ............................................................ 14

               1.1.6.2.5. **Question Dialog Box** ................................................................. 15

               1.1.6.2.6. **The Select File Dialog Box** .......................................................... 15

                   1.1.6.2.6.1. **The Select File Dialog Box (Windows)** ................................... 15

                   1.1.6.2.6.2. **The Select File Dialog Box (Linux)** ...................................... 16

       1.1.7. **Graphics Windows** .................................................................................. 19

           1.1.7.1. **Printing the Contents of the Graphics Window (Windows Systems Only)** ... 21

           1.1.7.2. **Using the Page Setup Dialog Box (Windows Systems Only)** ............... 21

   1.2. **Customizing the Graphical User Interface (Linux Systems Only)** ..................... 23

   1.3. **Using the GUI Help System** ......................................................................... 24

       1.3.1. **Task Page and Dialog Box Help** ............................................................ 25

       1.3.2. **Context-Sensitive Help (Linux Only)** ...................................................... 25

       1.3.3. **Opening the User’s Guide Table of Contents** ........................................ 25

       1.3.4. **Opening the Reference Guide** ............................................................... 26

       1.3.5. **Help on Help** ....................................................................................... 27

       1.3.6. **Accessing Printable (PDF) Manuals** .................................................... 27
3. Reading and Writing Files ................................................................. 41
   3.1. Shortcuts for Reading and Writing Files .................................................. 41
      3.1.1. Default File Suffixes .................................................................. 42
      3.1.2. Binary Files .............................................................................. 43
      3.1.3. Detecting File Format ................................................................. 43
      3.1.4. Recent File List ........................................................................... 43
      3.1.5. Reading and Writing Compressed Files ................................................ 43
         3.1.5.1. Reading Compressed Files ...................................................... 43
         3.1.5.2. Writing Compressed Files ...................................................... 44
      3.1.6. Tilde Expansion (Linux Systems Only) ................................................ 45
      3.1.7. Automatic Numbering of Files ......................................................... 45
      3.1.8. Disabling the Overwrite Confirmation Prompt ....................................... 46
      3.1.9. Toolbar Buttons ......................................................................... 46
   3.2. Reading Mesh Files ........................................................................... 46
   3.3. Reading and Writing Case and Data Files ................................................. 47
      3.3.1. Reading and Writing Case Files .................................................... 48
      3.3.2. Reading and Writing Data Files ..................................................... 48
      3.3.3. Reading and Writing Case and Data Files Together ............................ 49
      3.3.4. Automatic Saving of Case and Data Files ......................................... 49
   3.4. Reading and Writing Parallel Data Files ............................................... 52
      3.4.1. Writing Parallel Data Files ............................................................ 52
      3.4.2. Reading Parallel Data Files ........................................................... 53
      3.4.3. Availability and Limitations .......................................................... 53
   3.5. Reading Fluent/UNS and RAMPANT Case and Data Files ......................... 54
   3.6. Reading and Writing Profile Files ......................................................... 54
      3.6.1. Reading Profile Files .................................................................. 54
      3.6.2. Writing Profile Files .................................................................... 55
3.7. Reading and Writing Boundary Conditions .......................................................... 56
3.8. Writing a Boundary Mesh ......................................................................................... 57
3.9. Reading Scheme Source Files .................................................................................. 57
3.10. Creating and Reading Journal Files ......................................................................... 57
  3.10.1. Procedure ........................................................................................................ 59
3.11. Creating Transcript Files ......................................................................................... 59
3.12. Importing Files ........................................................................................................ 60
  3.12.1. ABAQUS Files ................................................................................................. 62
  3.12.2. CFX Files ....................................................................................................... 62
  3.12.3. Meshes and Data in CGNS Format ................................................................. 63
  3.12.4. EnSight Files .................................................................................................. 64
  3.12.5. ANSYS FIDAP Neutral Files ......................................................................... 64
  3.12.6. GAMBIT and GeoMesh Mesh Files ............................................................... 64
  3.12.7. HYPERMESH ASCII Files ............................................................................. 64
  3.12.8. I-deas Universal Files .................................................................................... 65
  3.12.9. LSTC Files ...................................................................................................... 65
  3.12.10. Marc POST Files .......................................................................................... 65
  3.12.11. Mechanical APDL Files ............................................................................... 66
  3.12.12. NASTRAN Files .......................................................................................... 66
  3.12.13. PATRAN Neutral Files ............................................................................... 66
  3.12.14. PLOT3D Files ............................................................................................... 66
  3.12.15. PTC Mechanica Design Files ...................................................................... 67
  3.12.16. Tecplot Files ................................................................................................. 67
  3.12.17. Fluent 4 Case Files ...................................................................................... 67
  3.12.18. PreBFC Files ............................................................................................... 68
  3.12.19. Partition Files ............................................................................................... 68
  3.12.20. CHEMKIN Mechanism .............................................................................. 68
3.13. Exporting Solution Data ......................................................................................... 68
  3.13.1. Exporting Limitations ................................................................................... 69
3.14. Exporting Solution Data after a Calculation .......................................................... 70
  3.14.1. ABAQUS Files ................................................................................................. 71
  3.14.2. Mechanical APDL Files ................................................................................. 72
  3.14.3. Mechanical APDL Input Files ....................................................................... 73
  3.14.4. ASCII Files .................................................................................................... 73
  3.14.5. AVS Files ....................................................................................................... 74
  3.14.6. ANSYS CFD-Post-Compatible Files ............................................................... 74
  3.14.7. CGNS Files .................................................................................................... 75
  3.14.8. Data Explorer Files ....................................................................................... 75
  3.14.9. EnSight Case Gold Files .............................................................................. 76
  3.14.10. FAST Files ................................................................................................... 78
  3.14.11. FAST Solution Files .................................................................................... 79
  3.14.13. I-deas Universal Files .................................................................................. 80
  3.14.14. NASTRAN Files .......................................................................................... 80
  3.14.15. PATRAN Files ............................................................................................. 81
  3.14.16. RadTherm Files ........................................................................................... 81
  3.14.17. Tecplot Files ............................................................................................... 82
3.15. Exporting Steady-State Particle History Data ......................................................... 82
3.16. Exporting Data During a Transient Calculation ..................................................... 84
  3.16.1. Creating Automatic Export Definitions for Solution Data ................................ 85
  3.16.2. Creating Automatic Export Definitions for Transient Particle History Data .......... 88
3.17. Exporting to ANSYS CFD-Post .............................................................................. 90
5.7. Converting the Mesh to a Polyhedral Mesh ................................................................. 168
  5.7.1. Converting the Domain to a Polyhedra ................................................................. 169
    5.7.1.1. Limitations ................................................................. 172
  5.7.2. Converting Skewed Cells to Polyhedra ................................................................. 173
    5.7.2.1. Limitations ................................................................. 173
    5.7.2.2. Using the Convert Skewed Cells Dialog Box ..................................................... 174
  5.7.3. Converting Cells with Hanging Nodes / Edges to Polyhedra ..................................... 174
    5.7.3.1. Limitations ................................................................. 175
5.8. Modifying the Mesh ..................................................................................................... 175
  5.8.1. Merging Zones ......................................................................................................... 176
    5.8.1.1. When to Merge Zones ......................................................................................... 176
    5.8.1.2. Using the Merge Zones Dialog Box ........................................................................ 177
  5.8.2. Separating Zones ..................................................................................................... 177
    5.8.2.1. Separating Face Zones ......................................................................................... 178
      5.8.2.1.1. Methods for Separating Face Zones ............................................................... 178
      5.8.2.1.2. Inputs for Separating Face Zones ................................................................... 178
    5.8.2.2. Separating Cell Zones ......................................................................................... 180
      5.8.2.2.1. Methods for Separating Cell Zones ............................................................... 180
      5.8.2.2.2. Inputs for Separating Cell Zones ................................................................... 180
  5.8.3. Fusing Face Zones .................................................................................................... 182
    5.8.3.1. Inputs for Fusing Face Zones ............................................................................... 182
      5.8.3.1.1. Fusing Zones on Branch Cuts ......................................................................... 183
  5.8.4. Creating Conformal Periodic Zones .......................................................................... 184
  5.8.5. Slitting Periodic Zones ............................................................................................. 185
  5.8.6. Slitting Face Zones .................................................................................................. 185
    5.8.6.1. Inputs for Slitting Face Zones .............................................................................. 186
  5.8.7. Orienting Face Zones ............................................................................................... 186
  5.8.8. Extruding Face Zones ............................................................................................... 186
    5.8.8.1. Specifying Extrusion by Displacement Distances ................................................ 187
    5.8.8.2. Specifying Extrusion by Parametric Coordinates ............................................... 187
  5.8.9. Replacing, Deleting, Deactivating, and Activating Zones ......................................... 187
    5.8.9.1. Replacing Zones ................................................................................................. 187
    5.8.9.2. Deleting Zones ................................................................................................. 189
    5.8.9.3. Deactivating Zones ........................................................................................... 189
    5.8.9.4. Activating Zones ............................................................................................... 190
  5.8.10. Copying Cell Zones ................................................................................................. 191
  5.8.11. Replacing the Mesh ................................................................................................. 191
    5.8.11.1. Inputs for Replacing the Mesh .......................................................................... 192
    5.8.11.2. Limitations ....................................................................................................... 192
  5.8.12. Managing Adjacent Zones ...................................................................................... 193
    5.8.12.1. Renaming Zones Using the Adjacency Dialog Box ........................................... 195
  5.8.13. Reordering the Domain and Zones ......................................................................... 195
    5.8.13.1. About Reordering ............................................................................................ 196
  5.8.14. Scaling the Mesh .................................................................................................... 196
    5.8.14.1. Using the Scale Mesh Dialog Box ...................................................................... 197
      5.8.14.1.1. Changing the Unit of Length ....................................................................... 198
      5.8.14.1.2. Unscaling the Mesh ..................................................................................... 198
      5.8.14.1.3. Changing the Physical Size of the Mesh ....................................................... 198
  5.8.15. Translating the Mesh ............................................................................................. 198
    5.8.15.1. Using the Translate Mesh Dialog Box ............................................................... 199
    5.8.16. Rotating the Mesh ................................................................................................. 199
      5.8.16.1. Using the Rotate Mesh Dialog Box .................................................................. 200
### 6. Cell Zone and Boundary Conditions

#### 6.1. Overview

- 6.1.1. Available Cell Zone and Boundary Types .................................................. 201
- 6.1.2. The Cell Zone and Boundary Conditions Task Page ........................................ 202
- 6.1.3. Changing Cell and Boundary Zone Types .................................................. 203
  - 6.1.3.1. Categories of Zone Types ................................................................. 204
- 6.1.4. Setting Cell Zone and Boundary Conditions .................................................. 204
- 6.1.5. Copying Cell Zone and Boundary Conditions .................................................. 205
- 6.1.6. Changing Cell or Boundary Zone Names .................................................. 206
- 6.1.7. Defining Non-Uniform Cell Zone and Boundary Conditions ......................... 206
- 6.1.8. Defining and Viewing Parameters .......................................................... 206
  - 6.1.8.1. Creating a New Parameter ................................................................. 209
  - 6.1.8.2. Working With Advanced Parameter Options .......................................... 210
    - 6.1.8.2.1. Defining Scheme Procedures With Input Parameters ...................... 210
    - 6.1.8.2.2. Defining UDFs With Input Parameters ........................................... 212
    - 6.1.8.2.3. Using the Text User Interface to Define UDFs and Scheme Procedures With Input Parameters 212
- 6.1.9. Selecting Cell or Boundary Zones in the Graphics Display ......................... 213
- 6.1.10. Operating and Periodic Conditions ...................................................... 214
- 6.1.11. Highlighting Selected Boundary Zones .................................................. 214
- 6.1.12. Saving and Reusing Cell Zone and Boundary Conditions ......................... 215

#### 6.2. Cell Zone Conditions

- 6.2.1. Fluid Conditions ......................................................................................... 215
  - 6.2.1.1. Inputs for Fluid Zones ........................................................................... 216
    - 6.2.1.1.1. Defining the Fluid Material ........................................................... 217
    - 6.2.1.1.2. Defining Sources ........................................................................... 217
    - 6.2.1.1.3. Defining Fixed Values ................................................................... 217
    - 6.2.1.1.4. Specifying a Laminar Zone ............................................................ 217
    - 6.2.1.1.5. Specifying a Reaction Mechanism ................................................ 217
    - 6.2.1.1.6. Specifying the Rotation Axis ........................................................ 218
    - 6.2.1.1.7. Defining Zone Motion ................................................................... 218
    - 6.2.1.1.8. Defining Radiation Parameters .................................................... 221
  - 6.2.1.2.1. Defining the Solid Material ............................................................. 222
  - 6.2.1.2. Defining a Heat Source ....................................................................... 222
  - 6.2.1.3. Defining a Fixed Temperature ............................................................. 222
  - 6.2.1.4. Specifying the Rotation Axis ............................................................... 223
  - 6.2.1.5. Defining Zone Motion ....................................................................... 223
  - 6.2.1.6. Defining Radiation Parameters ........................................................... 223
- 6.2.2. Solid Conditions ......................................................................................... 221
  - 6.2.2.1. Inputs for Solid Zones ......................................................................... 221
    - 6.2.2.1.1. Defining the Solid Material ............................................................ 222
    - 6.2.2.1.2. Defining a Heat Source ................................................................. 222
    - 6.2.2.1.3. Defining a Fixed Temperature ........................................................ 222
    - 6.2.2.1.4. Specifying the Rotation Axis ........................................................ 223
    - 6.2.2.1.5. Defining Zone Motion ................................................................. 223
    - 6.2.2.1.6. Defining Radiation Parameters .................................................... 223
- 6.2.3. Porous Media Conditions ............................................................................ 223
  - 6.2.3.1. Limitations and Assumptions of the Porous Media Model ..................... 224
  - 6.2.3.2. Momentum Equations for Porous Media ............................................. 224
    - 6.2.3.2.1. Darcy's Law in Porous Media ....................................................... 225
    - 6.2.3.2.2. Inertial Losses in Porous Media .................................................... 226
  - 6.2.3.3. Treatment of the Energy Equation in Porous Media ......................... 226
    - 6.2.3.3.1. Equilibrium Thermal Model Equations ......................................... 227
    - 6.2.3.3.2. Non-Equilibrium Thermal Model Equations .................................. 227
  - 6.2.3.4. Treatment of Turbulence in Porous Media .......................................... 228
  - 6.2.3.5. Effect of Porosity on Transient Scalar Equations .................................. 229
  - 6.2.3.6. User Inputs for Porous Media ............................................................. 229
    - 6.2.3.6.1. Defining the Porous Zone .............................................................. 230
6.2.3.6.2. Defining the Porous Velocity Formulation .......................................................... 230
6.2.3.6.3. Defining the Fluid Passing Through the Porous Medium ..................................... 231
6.2.3.6.4. Enabling Reactions in a Porous Zone ............................................................... 231
6.2.3.6.5. Including the Relative Velocity Resistance Formulation ........................................ 231
6.2.3.6.6. Defining the Viscous and Inertial Resistance Coefficients ....................................... 231
6.2.3.6.7. Deriving Porous Media Inputs Based on Superficial Velocity, Using a Known Pressure Loss .......................................................... 234
6.2.3.6.8. Using the Ergun Equation to Derive Porous Media Inputs for a Packed Bed .......... 235
6.2.3.6.9. Using an Empirical Equation to Derive Porous Media Inputs for Turbulent Flow Through a Perforated Plate ......................................................................................... 236
6.2.3.6.10. Using Tabulated Data to Derive Porous Media Inputs for Laminar Flow Through a Fibrous Mat .......................................................... 237
6.2.3.6.11. Deriving the Porous Coefficients Based on Experimental Pressure and Velocity Data .................................................................................................................. 237
6.2.3.6.12. Using the Power-Law Model ................................................................................. 238
6.2.3.6.13. Defining Porosity ............................................................................................... 238
6.2.3.6.14. Specifying the Heat Transfer Settings .............................................................. 239
6.2.3.6.14.1. Equilibrium Thermal Model ........................................................................... 239
6.2.3.6.14.2. Non-Equilibrium Thermal Model .................................................................... 239
6.2.3.6.15. Defining Sources ............................................................................................... 242
6.2.3.6.16. Defining Fixed Values ....................................................................................... 242
6.2.3.6.17. Suppressing the Turbulent Viscosity in the Porous Region .................................... 242
6.2.3.6.18. Specifying the Rotation Axis and Defining Zone Motion ....................................... 242
6.2.3.7. Modeling Porous Media Based on Physical Velocity ............................................. 243
6.2.3.7.1. Single Phase Porous Media .................................................................................... 243
6.2.3.7.2. Multiphase Porous Media ...................................................................................... 244
6.2.3.7.2.1. The Continuity Equation .................................................................................... 244
6.2.3.7.2.2. The Momentum Equation .................................................................................. 244
6.2.3.7.2.3. The Energy Equation ........................................................................................ 245
6.2.3.8. Solution Strategies for Porous Media ......................................................................... 245
6.2.3.9. Postprocessing for Porous Media ............................................................................ 246
6.2.4. Fixing the Values of Variables ..................................................................................... 247
6.2.4.1. Overview of Fixing the Value of a Variable ............................................................. 247
6.2.4.1.1. Variables That Can Be Fixed ................................................................................ 248
6.2.4.2. Procedure for Fixing Values of Variables in a Zone ................................................ 248
6.2.4.2.1. Fixing Velocity Components ................................................................................. 249
6.2.4.2.2. Fixing Temperature and Enthalpy ......................................................................... 249
6.2.4.2.3. Fixing Species Mass Fractions .............................................................................. 250
6.2.4.2.4. Fixing Turbulence Quantities ................................................................................ 250
6.2.4.2.5. Fixing User-Defined Scalars ............................................................................... 250
6.2.5. Locking the Temperature for Solid and Shell Zones ..................................................... 251
6.2.6. Defining Mass, Momentum, Energy, and Other Sources ........................................... 251
6.2.6.1. Sign Conventions and Units .................................................................................... 252
6.2.6.2. Procedure for Defining Sources ............................................................................... 252
6.2.6.2.1. Mass Sources ....................................................................................................... 253
6.2.6.2.2. Momentum Sources ............................................................................................. 253
6.2.6.2.3. Energy Sources .................................................................................................... 253
6.2.6.2.4. Turbulence Sources ............................................................................................... 253
6.2.6.2.4.1. Turbulence Sources for the k-ε Model ............................................................ 253
6.2.6.2.4.2. Turbulence Sources for the Spalart-Allmaras Model ......................................... 254
6.2.6.2.4.3. Turbulence Sources for the k-ω Model ............................................................ 254
6.2.6.2.4.4. Turbulence Sources for the Reynolds Stress Model .......................................... 254
6.3. Boundary Conditions .............................................................................................................. 255
6.3.1. Flow Inlet and Exit Boundary Conditions ........................................................................ 256
6.3.2. Using Flow Boundary Conditions .................................................................................... 256
6.3.2.1. Determining Turbulence Parameters ........................................................................... 257
6.3.2.1.1. Specification of Turbulence Quantities Using Profiles ............................................ 257
6.3.2.1.2. Uniform Specification of Turbulence Quantities .................................................... 258
6.3.2.1.3. Turbulence Intensity ................................................................................................. 258
6.3.2.1.4. Turbulence Length Scale and Hydraulic Diameter ................................................ 258
6.3.2.1.5. Turbulent Viscosity Ratio ........................................................................................ 259
6.3.2.1.6. Relationships for Deriving Turbulence Quantities .................................................. 259
6.3.2.1.7. Estimating Modified Turbulent Viscosity from Turbulence Intensity and Length Scale ......................................................................................................................... 259
6.3.2.1.8. Estimating Turbulent Kinetic Energy from Turbulence Intensity ................................. 260
6.3.2.1.9. Estimating Turbulent Dissipation Rate from a Length Scale ..................................... 260
6.3.2.1.10. Estimating Turbulent Dissipation Rate from Turbulent Viscosity Ratio ................. 260
6.3.2.1.11. Estimating Turbulent Dissipation Rate for Decaying Turbulence ............................ 260
6.3.2.1.12. Estimating Specific Dissipation Rate from a Length Scale ....................................... 261
6.3.2.1.13. Estimating Specific Dissipation Rate from Turbulent Viscosity Ratio .................... 261
6.3.2.1.14. Estimating Reynolds Stress Components from Turbulent Kinetic Energy .............. 261
6.3.2.1.15. Specifying Inlet Turbulence for LES ....................................................................... 262
6.3.3. Pressure Inlet Boundary Conditions ................................................................................. 262
6.3.3.1. Inputs at Pressure Inlet Boundaries .............................................................................. 262
6.3.3.1.1. Summary .................................................................................................................. 262
6.3.3.1.1.1. Pressure Inputs and Hydrostatic Head ................................................................. 263
6.3.3.1.1.2. Defining Total Pressure and Temperature .......................................................... 264
6.3.3.1.1.3. Defining the Flow Direction ................................................................................... 265
6.3.3.1.1.4. Defining Static Pressure ....................................................................................... 268
6.3.3.1.1.5. Defining Turbulence Parameters ......................................................................... 268
6.3.3.1.1.6. Defining Radiation Parameters ............................................................................. 268
6.3.3.1.1.7. Defining Species Mass or Mole Fractions ............................................................ 268
6.3.3.1.1.8. Defining Non-Premixed Combustion Parameters ............................................... 268
6.3.3.1.1.9. Defining Premixed Combustion Boundary Conditions ......................................... 269
6.3.3.1.1.10. Defining Discrete Phase Boundary Conditions ................................................... 269
6.3.3.1.1.11. Defining Multiphase Boundary Conditions .......................................................... 269
6.3.3.1.1.12. Defining Open Channel Boundary Conditions .................................................... 269
6.3.3.2. Default Settings at Pressure Inlet Boundaries ............................................................... 269
6.3.3.3. Calculation Procedure at Pressure Inlet Boundaries .................................................... 269
6.3.3.3.1. Incompressible Flow Calculations at Pressure Inlet Boundaries ............................... 269
6.3.3.3.2. Compressible Flow Calculations at Pressure Inlet Boundaries ................................. 270
6.3.4. Velocity Inlet Boundary Conditions .................................................................................. 270
6.3.4.1. Inputs at Velocity Inlet Boundaries .............................................................................. 271
6.3.4.1.1. Summary .................................................................................................................. 271
6.3.4.1.2. Defining the Velocity ................................................................................................. 272
6.3.4.1.3. Setting the Velocity Magnitude and Direction ....................................................... 273
6.3.4.1.4. Setting the Velocity Magnitude Normal to the Boundary ........................................ 273
6.3.4.1.5. Setting the Velocity Components ............................................................................. 273
6.3.4.1.6. Setting the Angular Velocity .................................................................................... 274
6.3.8.3. Calculation Procedure at Pressure Outlet Boundaries .......................................................... 293
  6.3.8.3.1. Pressure-Based Solver Implementation ............................................................................ 293
  6.3.8.3.2. Density-Based Solver Implementation ............................................................................. 294
6.3.8.4. Other Optional Inputs at Pressure Outlet Boundaries .......................................................... 295
  6.3.8.4.1. Non-Reflecting Boundary Conditions Option ................................................................. 295
  6.3.8.4.2. Target Mass Flow Rate Option .......................................................................................... 296
  6.3.8.4.3. Limitations ....................................................................................................................... 296
  6.3.8.4.4. Target Mass Flow Rate Settings ....................................................................................... 296
  6.3.8.4.5. Solution Strategies When Using the Target Mass Flow Rate Option ......................... 297
  6.3.8.4.6. Setting Target Mass Flow Rates Using UDFs ................................................................. 298
6.3.9. Pressure Far-Field Boundary Conditions ................................................................................. 298
  6.3.9.1. Limitations .......................................................................................................................... 298
  6.3.9.2. Inputs at Pressure Far-Field Boundaries .............................................................................. 298
    6.3.9.2.1. Summary .......................................................................................................................... 298
    6.3.9.2.2. Defining Static Pressure, Mach Number, and Static Temperature ................................. 299
    6.3.9.2.3. Defining the Flow Direction ............................................................................................ 299
    6.3.9.2.4. Defining Turbulence Parameters ..................................................................................... 300
    6.3.9.2.5. Defining Radiation Parameters ....................................................................................... 300
    6.3.9.2.6. Defining Species Transport Parameters ......................................................................... 300
    6.3.9.3. Defining Discrete Phase Boundary Conditions .................................................................. 300
  6.3.9.4. Default Settings at Pressure Far-Field Boundaries ............................................................. 300
  6.3.9.5. Calculation Procedure at Pressure Far-Field Boundaries ................................................... 300
6.3.10. Outflow Boundary Conditions ............................................................................................. 301
  6.3.10.1. ANSYS Fluent’s Treatment at Outflow Boundaries ......................................................... 302
  6.3.10.2. Using Outflow Boundaries ............................................................................................... 302
  6.3.10.3. Mass Flow Split Boundary Conditions .............................................................................. 303
  6.3.10.4. Other Inputs at Outflow Boundaries .................................................................................. 304
    6.3.10.4.1. Radiation Inputs at Outflow Boundaries ........................................................................ 304
    6.3.10.4.2. Defining Discrete Phase Boundary Conditions ............................................................. 304
  6.3.11. Outlet Vent Boundary Conditions ....................................................................................... 304
    6.3.11.1. Inputs at Outlet Vent Boundaries ..................................................................................... 304
      6.3.11.1.1. Specifying the Loss Coefficient .................................................................................... 306
    6.3.12. Exhaust Fan Boundary Conditions ..................................................................................... 307
      6.3.12.1. Inputs at Exhaust Fan Boundaries .................................................................................. 307
        6.3.12.1.1. Specifying the Pressure Jump .................................................................................... 307
    6.3.13. Degassing Boundary Conditions ......................................................................................... 308
      6.3.13.1. Limitations ....................................................................................................................... 308
      6.3.13.2. Inputs at Degassing Boundaries ..................................................................................... 309
    6.3.14. Wall Boundary Conditions .................................................................................................. 309
      6.3.14.1. Inputs at Wall Boundaries ............................................................................................... 309
        6.3.14.1.1. Summary ....................................................................................................................... 309
        6.3.14.2. Wall Motion ...................................................................................................................... 310
          6.3.14.2.1. Defining a Stationary Wall ......................................................................................... 310
          6.3.14.2.2. Velocity Conditions for Moving Walls ........................................................................ 311
          6.3.14.2.3. Shear Conditions at Walls .......................................................................................... 312
          6.3.14.2.4. No-Slip Walls ............................................................................................................. 313
          6.3.14.2.5. Specified Shear ............................................................................................................ 313
          6.3.14.2.6. Specularity Coefficient .............................................................................................. 313
          6.3.14.2.7. Marangoni Stress ......................................................................................................... 314
          6.3.14.2.9. Law-of-the-Wall Modified for Roughness ................................................................. 315
          6.3.14.2.10. Setting the Roughness Parameters ............................................................................. 317
6.3.14.3. Thermal Boundary Conditions at Walls .................................................. 318
6.3.14.3.1. Heat Flux Boundary Conditions .................................................. 319
6.3.14.3.2. Temperature Boundary Conditions .................................................. 319
6.3.14.3.3. Convective Heat Transfer Boundary Conditions ............................................. 319
6.3.14.3.4. External Radiation Boundary Conditions .................................................. 320
6.3.14.3.5. Combined Convection and External Radiation Boundary Conditions ................. 320
6.3.14.3.6. Augmented Heat Transfer .................................................. 320
6.3.14.3.7. Thin-Wall Thermal Resistance Parameters .................................................. 320
6.3.14.3.8. Thermal Conditions for Two-Sided Walls .................................................. 322
6.3.14.3.9. Shell Conduction .................................................. 323
6.3.14.4. Species Boundary Conditions for Walls .................................................. 325
6.3.14.4.1. Reaction Boundary Conditions for Walls .................................................. 326
6.3.14.5. Radiation Boundary Conditions for Walls .................................................. 327
6.3.14.6. Discrete Phase Model (DPM) Boundary Conditions for Walls ............................ 327
6.3.14.6.1. Wall Adhesion Contact Angle for VOF Model .................................................. 327
6.3.14.8. Wall Film Boundary Conditions for Walls .................................................. 327
6.3.14.9. Default Settings at Wall Boundaries .................................................. 327
6.3.14.10. Shear-Stress Calculation Procedure at Wall Boundaries .................................... 328
6.3.14.10.1. Shear-Stress Calculation in Laminar Flow .................................................. 328
6.3.14.10.2. Shear-Stress Calculation in Turbulent Flows .................................................. 328
6.3.14.11. Heat Transfer Calculations at Wall Boundaries .................................................. 328
6.3.14.11.1. Temperature Boundary Conditions .................................................. 328
6.3.14.11.2. Heat Flux Boundary Conditions .................................................. 329
6.3.14.11.3. Convective Heat Transfer Boundary Conditions .................................................. 329
6.3.14.11.4. External Radiation Boundary Conditions .................................................. 329
6.3.14.11.5. Combined External Convection and Radiation Boundary Conditions ................. 330
6.3.14.11.6. Calculation of the Fluid-Side Heat Transfer Coefficient ...................................... 330
6.3.15. Symmetry Boundary Conditions .................................................. 330
6.3.15.1. Examples of Symmetry Boundaries .................................................. 331
6.3.15.2. Calculation Procedure at Symmetry Boundaries .................................................. 332
6.3.16. Periodic Boundary Conditions .................................................. 332
6.3.16.1. Examples of Periodic Boundaries .................................................. 333
6.3.16.2. Inputs for Periodic Boundaries .................................................. 333
6.3.16.3. Default Settings at Periodic Boundaries .................................................. 335
6.3.16.4. Calculation Procedure at Periodic Boundaries .................................................. 335
6.3.17. Axis Boundary Conditions .................................................. 335
6.3.17.1. Calculation Procedure at Axis Boundaries .................................................. 335
6.3.18. Fan Boundary Conditions .................................................. 335
6.3.18.1. Fan Equations .................................................. 336
6.3.18.1.1. Modeling the Pressure Rise Across the Fan .................................................. 336
6.3.18.1.2. Modeling the Fan Swirl Velocity .................................................. 336
6.3.18.2. User Inputs for Fans .................................................. 337
6.3.18.2.1. Identifying the Fan Zone .................................................. 337
6.3.18.2.2. Defining the Pressure Jump .................................................. 338
6.3.18.2.2.1. Polynomial, Piecewise-Linear, or Piecewise-Polynomial Function ................. 338
6.3.18.2.2.2. Constant Value .................................................. 339
6.3.18.2.2.3. User-Defined Function or Profile .................................................. 339
6.3.18.2.2.4. Example: Determining the Pressure Jump Function .............................................. 339
6.3.18.2.3. Defining Discrete Phase Boundary Conditions for the Fan ............................................. 340
6.3.18.2.4. Defining the Fan Swirl Velocity .................................................. 341
6.6. Profiles .................................................................................................................. 377
  6.6.1. Profile Specification Types .............................................................................. 377
  6.6.2. Profile File Format .......................................................................................... 378
    6.6.2.1. Example ..................................................................................................... 379
  6.6.3. Using Profiles .................................................................................................. 380
    6.6.3.1. Checking and Deleting Profiles ................................................................. 381
    6.6.3.2. Viewing Profile Data .................................................................................. 382
    6.6.3.3. Example ..................................................................................................... 382
  6.6.4. Reorienting Profiles ......................................................................................... 383
    6.6.4.1. Steps for Changing the Profile Orientation ............................................... 383
    6.6.4.2. Profile Orienting Example ......................................................................... 386
  6.6.5. Defining Transient Cell Zone and Boundary Conditions .................................. 388
    6.6.5.1. Standard Transient Profiles ...................................................................... 389
    6.6.5.2. Tabular Transient Profiles ......................................................................... 390
  6.7. Coupling Boundary Conditions with GT-Power ................................................... 391
    6.7.1. Requirements and Restrictions ..................................................................... 391
    6.7.2. User Inputs ................................................................................................... 392
  6.8. Coupling Boundary Conditions with WAVE ....................................................... 393
    6.8.1. Requirements and Restrictions ..................................................................... 394
    6.8.2. User Inputs ................................................................................................... 395
 7. Physical Properties .................................................................................................... 397
  7.1. Defining Materials ............................................................................................... 397
    7.1.1. Physical Properties for Solid Materials ....................................................... 398
    7.1.2. Material Types and Databases ...................................................................... 398
    7.1.3. Using the Materials Task Page ...................................................................... 399
      7.1.3.1. Modifying Properties of an Existing Material ........................................... 400
      7.1.3.2. Renaming an Existing Material ................................................................. 400
      7.1.3.3. Copying Materials from the ANSYS Fluent Database .................................. 401
      7.1.3.4. Creating a New Material ......................................................................... 403
      7.1.3.5. Saving Materials and Properties ............................................................... 403
      7.1.3.6. Deleting a Material .................................................................................. 403
      7.1.3.7. Changing the Order of the Materials List .................................................. 404
    7.1.4. Using a User-Defined Materials Database ...................................................... 404
      7.1.4.1. Opening a User-Defined Database ............................................................ 405
      7.1.4.2. Viewing Materials in a User-Defined Database ........................................... 405
      7.1.4.3. Copying Materials from a User-Defined Database ...................................... 406
      7.1.4.4. Copying Materials from the Case to a User-Defined Database ..................... 407
      7.1.4.5. Modifying Properties of an Existing Material ............................................. 408
      7.1.4.6. Creating a New Materials Database and Materials .................................... 408
      7.1.4.7. Deleting Materials from a Database ............................................................ 411
  7.2. Defining Properties Using Temperature-Dependent Functions .......................... 412
    7.2.1. Inputs for Polynomial Functions .................................................................... 412
    7.2.2. Inputs for Piecewise-Linear Functions ........................................................... 413
    7.2.3. Inputs for Piecewise-Polynomial Functions .................................................... 415
    7.2.4. Checking and Modifying Existing Profiles ..................................................... 416
  7.3. Density .................................................................................................................. 416
    7.3.1. Defining Density for Various Flow Regimes .................................................. 416

7.5. Thermal Conductivity ................................................ ................................................... ................. 434
7.4. Viscosity .............................................. ................................................... ...................................... 424
7.3.3. Inputs for the Boussinesq Approximation ............................................... ............................... 417
7.7. Specific Heat Capacity ................................................. ................................................... ............... 449
7.3.4. Compressible Liquid Density Method ................................................ ............................................ 417
7.7.1. Input of Constant Specific Heat Capacity ................................................. .............................. 450
7.3.4.1. Compressible Liquid Inputs ................................................ ............................................. 418
7.7.5. Anisotropic Thermal Conductivity for Solids .................................................. ........................ 437
7.3.4.2. Compressible Liquid Density Method Availability ................................................ ......... 420
7.4.1. Input of Constant Viscosity ............................................... ................................................... . 425
7.7.5.1. Anisotropic Thermal Conductivity ................................................ ................................ 438
7.3.4.5. Viscosity for Non-Newtonian Fluids .................................................. ..................................... 429
7.3.5. Density as a Profile Function of Temperature ............................................. ......................................... 421
7.5.2. Thermal Conductivity as a Function of Temperature ............................................. ................. 435
7.4.2. Viscosity as a Function of Temperature ............................................. ..................................... 425
7.5.3. Thermal Conductivity Using Kinetic Theory ................................................ ........................... 436
7.4.3. Defining the Viscosity Using Kinetic Theory .................................................. ..................................... 430
7.5.5. Anisotropic Thermal Conductivity ................................................ ................................ 440
7.4.5.1. Temperature Dependent Viscosity ............................................... ................................. 429
7.5.5.1. Anisotropic Thermal Conductivity ................................................ ................................ 438
7.4.5.2. Power Law for Non-Newtonian Viscosity ................................................ .......................... 431
7.5.5.2. Biaxial Thermal Conductivity ................................................ ........................................ 439
7.4.5.2.1. Inputs for the Power Law .................................................. ........................................... 427
7.5.5.3. Orthotropic Thermal Conductivity ................................................ ................................ 440
7.4.5.3. The Carreau Model for Pseudo-Plastics ................................................. ........................ 431
7.4.5.3.1. Inputs for the Carreau Model ................................................. .............................. 432
7.5.5.5. User-Defined Anisotropic Thermal Conductivity ................................................ ........... 443
7.4.5.4. Cross Model ................................................. ................................................... ............ 432
7.4.5.4.1. Inputs for the Cross Model ................................................. .................................. 434
7.4.5.5 Herschel-Bulkley Model for Bingham Plastics .................................................. .............. 433
7.5.5.5.1. Inputs for the Herschel-Bulkley Model ................................................ ................ 435
7.4.5.5.5. Cross Model ................................................. ................................................... ............ 433

7.3.1. Mixing Density Relationships in Multiple-Zone Models ................................................. 417
7.3.2. Input of Constant Density ................................................ ................................................... . 417
7.3.3. Inputs for the Boussinesq Approximation ............................................... ............................... 417
7.3.4. Compressible Liquid Density Method ................................................ ............................................ 417
7.3.4.1. Compressible Liquid Inputs ................................................ ............................................. 418
7.3.4.2. Compressible Liquid Density Method Availability ................................................ ......... 420
7.3.5. Density as a Profile Function of Temperature ............................................. ......................................... 421
7.3.6. Incompressible Ideal Gas Law ................................................ ................................................... . 421
7.3.6.1. Density Inputs for the Incompressible Ideal Gas Law ................................................ ......... 421
7.3.7. Ideal Gas Law for Compressible Flows ............................................. ..................................... 422
7.3.7.1. Density Inputs for the Ideal Gas Law for Compressible Flows ............................................. 422
7.3.8. Composition-Dependent Density for Multicomponent Mixtures ............................................. 423
7.6. User-Defined Scalar (UDS) Diffusivity ................................................. ............................................ 443
7.6.2.2. Orthotropic Diffusivity ................................................. ................................................. 446
7.6.2.3. Cylindrical Orthotropic Diffusivity ................................................. .............................. 447
7.6.3. User-Defined Anisotropic Diffusivity ................................................ ................................ 448
7.7. Specific Heat Capacity ................................................ ................................................... ............... 450
7.7.1. Input of Constant Specific Heat Capacity ................................................. .............................. 450
7.7.2. Specific Heat Capacity as a Function of Temperature ................................................ ............................................ 450
7.9. Mass Diffusion Coefficients ...................................................... 454
  7.9.1. Fickian Diffusion ............................................................. 455
    7.9.2. Full Multicomponent Diffusion ........................................ 456
      7.9.2.1. General Theory ..................................................... 456
        7.9.2.2. Maxwell-Stefan Equations ..................................... 456
    7.9.3. Anisotropic Species Diffusion ......................................... 457
    7.9.4. Thermal Diffusion Coefficients ....................................... 458
      7.9.4.1. Thermal Diffusion Coefficient Inputs ......................... 458
    7.9.5. Mass Diffusion Coefficient Inputs ................................... 460
      7.9.5.1. Constant Dilute Approximation Inputs ......................... 460
      7.9.5.2. Dilute Approximation Inputs .................................... 461
      7.9.5.3. Multicomponent Method Inputs .................................. 462
      7.9.5.4. Unity Lewis Number ................................................ 463
    7.9.6. Mass Diffusion Coefficient Inputs for Turbulent Flow ............ 463
  7.10. Standard State Enthalpies ................................................ 464
  7.11. Standard State Entropies .................................................. 464
  7.12. Unburnt Thermal Diffusivity ............................................... 465
  7.13. Kinetic Theory Parameters ................................................ 465
    7.13.1. Inputs for Kinetic Theory ......................................... 465
  7.14. Operating Pressure .......................................................... 466
    7.14.1. The Significance of Operating Pressure ............................ 466
    7.14.2. Operating Pressure, Gauge Pressure, and Absolute Pressure ...... 467
    7.14.3. Setting the Operating Pressure ...................................... 467
  7.15. Reference Pressure Location ................................................. 468
    7.15.1. Actual Reference Pressure Location ................................ 468
  7.16. Real Gas Models ............................................................... 468
    7.16.1. Introduction ............................................................ 469
    7.16.2. Choosing a Real Gas Model .......................................... 470
    7.16.3. Cubic Equation of State Models ...................................... 471
      7.16.3.1. Overview and Limitations ..................................... 471
      7.16.3.2. Equation of State ................................................ 473
      7.16.3.3. Enthalpy, Entropy, and Specific Heat Calculations .......... 475
      7.16.3.4. Critical Constants for Pure Components ...................... 476
      7.16.3.5. Calculations for Mixtures ..................................... 477
8. Modeling Basic Fluid Flow

8.1. User-Defined Scalar (UDS) Transport Equations

8.1.1. Introduction ................................................. 505
8.1.2. UDS Theory ................................................ ................................................... ....................... 505
8.1.2.1. Single Phase Flow ................................................. ................................................... .... 506
8.1.2.2. Multiphase Flow ................................................. ................................................... ...... 512
8.1.3. Setting Up UDS Equations in ANSYS Fluent .................. 508
8.1.3.1. Single Phase Flow ................................................. ................................................... .... 508
8.1.3.2. Multiphase Flow ................................................. ................................................... ...... 512
8.2. Periodic Flows ................................................ ................................................... .................. 514
8.2.1. Overview and Limitations ................................................ ................................................... ............. 514
8.2.1.1. Overview ................................................ ................................................... .................. 514
8.2.1.2. Limitations for Modeling Streamwise-Periodic Flow .... 515
8.2.2. User Inputs for the Pressure-Based Solver .................. 515
8.2.2.1. Setting Parameters for the Calculation of \( \beta \) ................................................ ................................................... .... 517

### 25. Modeling Multiphase Flows

25.1. Introduction ...................................................................................................................... 1243
25.2. Steps for Using a Multiphase Model .............................................................................. 1243
25.2.1. Enabling the Multiphase Model .................................................................................... 1245
25.2.2. Choosing a Volume Fraction Formulation .................................................................... 1247
  25.2.2.1. Explicit Schemes ...................................................................................................... 1247
  25.2.2.2. Implicit Schemes .................................................................................................... 1248
  25.2.2.2.1. Examples ............................................................................................................ 1249
  25.2.2.3. Volume Fraction Limits ........................................................................................ 1249
25.2.3. Solving a Homogeneous Multiphase Flow ................................................................. 1250
25.2.4. Defining the Phases ..................................................................................................... 1250
25.2.5. Including Body Forces ............................................................................................... 1251
25.2.6. Modeling Multiphase Species Transport .................................................................... 1251
25.2.7. Specifying Heterogeneous Reactions ........................................................................ 1253
25.2.8. Including Mass Transfer Effects ................................................................................ 1256
25.2.9. Defining Multiphase Cell Zone and Boundary Conditions ....................................... 1260
  25.2.9.1. Boundary Conditions for the Mixture and the Individual Phases ......................... 1261
    25.2.9.1.1. VOF Model ....................................................................................................... 1261
    25.2.9.1.2. Mixture Model ............................................................................................... 1262
    25.2.9.1.3. Eulerian Model ................................................................................................. 1264
  25.2.9.2. Steps for Setting Boundary Conditions ................................................................ 1269
  25.2.9.3. Steps for Copying Cell Zone and Boundary Conditions ...................................... 1273
25.3. Setting Up the VOF Model ............................................................................................. 1274
  25.3.1. Including Coupled Level Set with the VOF Model .................................................. 1274
  25.3.2. Modeling Open Channel Flows .................................................................................. 1275
    25.3.2.1. Defining Inlet Groups ......................................................................................... 1276
    25.3.2.2. Defining Outlet Groups ...................................................................................... 1276
    25.3.2.3. Setting the Inlet Group ....................................................................................... 1276
    25.3.2.4. Setting the Outlet Group .................................................................................... 1277
  25.3.2.5. Determining the Free Surface Level ..................................................................... 1277
  25.3.2.6. Determining the Bottom Level ............................................................................. 1278
  25.3.2.7. Specifying the Total Height .................................................................................. 1279
  25.3.2.8. Determining the Velocity Magnitude .................................................................... 1279
  25.3.2.9. Determining the Secondary Phase for the Inlet .................................................... 1279
  25.3.2.10. Choosing the Pressure Specification Method ................................................... 1280
  25.3.2.11. Choosing the Density Interpolation Method ..................................................... 1280
  25.3.2.12. Limitations .......................................................................................................... 1281
  25.3.2.13. Recommendations for Setting Up an Open Channel Flow Problem .................. 1282
25.3.3. Modeling Open Channel Wave Boundary Conditions ............................................. 1283
  25.3.3.1. Transient Profile Support for Wave Inputs .......................................................... 1289
25.3.4. Recommendations for Open Channel Initialization .................................................. 1289
  25.3.4.1. Reporting Parameters for Open Channel Wave BC option .................................. 1292
25.3.5. Numerical Beach Treatment for Open Channels ...................................................... 1292
25.3.5.1. Solution Strategies ................................................................. 1295
25.3.6. Defining the Phases for the VOF Model .................................................. 1296
  25.3.6.1. Defining the Primary Phase ......................................................... 1296
  25.3.6.2. Defining a Secondary Phase .......................................................... 1297
  25.3.6.3. Including Surface Tension and Adhesion Effects ................................ 1297
  25.3.6.4. Discretizing Using the Phase Localized Compressive Scheme .................... 1303
25.3.7. Setting Time-Dependent Parameters for the VOF Model ................................ 1305
25.3.8. Modeling Compressible Flows .......................................................... 1307
25.3.9. Modeling Solidification/Melting .......................................................... 1308
25.4. Setting Up the Mixture Model .................................................................. 1308
  25.4.1. Defining the Phases for the Mixture Model ............................................. 1308
    25.4.1.1. Defining the Primary Phase .............................................................. 1308
    25.4.1.2. Defining a Non-Granular Secondary Phase ............................................. 1308
    25.4.1.3. Defining a Granular Secondary Phase .................................................... 1310
    25.4.1.4. Defining the Interfacial Area Concentration .......................................... 1312
    25.4.1.5. Defining Drag Between Phases ........................................................... 1315
    25.4.1.6. Defining the Slip Velocity ................................................................. 1316
  25.4.2. Including Mixture Drift Force ............................................................ 1316
  25.4.3. Including Cavitation Effects .............................................................. 1316
  25.4.4. Modeling Compressible Flows ............................................................. 1317
25.5. Setting Up the Eulerian Model ................................................................. 1317
  25.5.1. Additional Guidelines for Eulerian Multiphase Simulations ......................... 1318
  25.5.2. Defining the Phases for the Eulerian Model ............................................. 1318
    25.5.2.1. Defining the Primary Phase .............................................................. 1318
    25.5.2.2. Defining a Non-Granular Secondary Phase ............................................. 1318
    25.5.2.3. Defining a Granular Secondary Phase .................................................... 1319
    25.5.2.4. Defining the Interfacial Area Concentration .......................................... 1323
    25.5.2.5. Defining the Interaction Between Phases .............................................. 1325
    25.5.2.5.1. Specifying the Drag Function .......................................................... 1325
    25.5.2.5.1.1. Drag Modification ........................................................................... 1328
    25.5.2.5.2. Specifying the Restitution Coefficients (Granular Flow Only) .................... 1328
    25.5.2.5.3. Including the Lift Force ................................................................. 1328
    25.5.2.5.4. Including the Wall Lubrication Force ................................................. 1329
    25.5.2.5.5. Including the Turbulent Dispersion Force .......................................... 1332
    25.5.2.5.6. Including Surface Tension and Wall Adhesion Effects ........................... 1335
    25.5.2.5.7. Including the Virtual Mass Force ..................................................... 1336
  25.5.3. Setting Time-Dependent Parameters for the Explicit Volume Fraction Scheme .... 1336
  25.5.4. Modeling Turbulence ............................................................................. 1336
    25.5.4.1. Including Turbulence Interaction Source Terms ....................................... 1338
    25.5.4.2. Customizing the k-ε Multiphase Turbulent Viscosity ................................. 1340
    25.5.5. Including Heat Transfer Effects ........................................................... 1340
    25.5.6. Using an Algebraic Interfacial Area Model ............................................. 1342
    25.5.7. Modeling Compressible Flows ............................................................. 1343
    25.5.8. Including the Dense Discrete Phase Model ............................................. 1343
    25.5.8.1. Defining a Granular Discrete Phase ...................................................... 1346
    25.5.9. Including the Boiling Model ................................................................. 1348
    25.5.10. Including the Multi-Fluid VOF Model .................................................. 1355
25.6. Setting Up the Wet Steam Model ............................................................... 1356
  25.6.1. Using User-Defined Thermodynamic Wet Steam Properties .......................... 1357
  25.6.2. Writing the User-Defined Wet Steam Property Functions (UDWSPF) .............. 1358
  25.6.3. Compiling Your UDWSPF and Building a Shared Library File ....................... 1360
  25.6.4. Loading the UDWSPF Shared Library File .............................................. 1361
25.6.5. UDWSPF Example .................................................................................. 1361
25.7. Solution Strategies for Multiphase Modeling .......................................................... 1366
  25.7.1. Coupled Solution for Eulerian Multiphase Flows ............................................ 1366
  25.7.2. Coupled Solution for VOF and Mixture Multiphase Flows ................................. 1368
  25.7.3. Selecting the Pressure-Velocity Coupling Method ......................................... 1369
    25.7.3.1. Limitations and Recommendations of the Coupled with Volume Fraction Options for the VOF and Mixture Models ................................. 1370
  25.7.4. Controlling the Volume Fraction Coupled Solution ..................................... 1371
  25.7.5. Setting Initial Volume Fractions ...................................................................... 1373
  25.7.6. VOF Model ................................................................................................. 1374
    25.7.6.1. Setting the Reference Pressure Location .................................................. 1374
    25.7.6.2. Pressure Interpolation Scheme ............................................................... 1374
    25.7.6.3. Discretization Scheme Selection for the Implicit and Explicit Formulations .............................................................................................................................. 1374
    25.7.6.4. High-Order Rhie-Chow Face Flux Interpolation ....................................... 1376
    25.7.6.5. Treatment of Unsteady Terms in Rhie-Chow Face Flux Interpolation .......... 1376
    25.7.6.6. Using Unstructured Variant of PRESTO Pressure Scheme ...................... 1377
    25.7.6.7. Pressure-Velocity Coupling and Under-Relaxation for the Time-dependent Formulations .................................................................................................................. 1377
    25.7.6.8. Under-Relaxation for the Steady-State Formulation ................................ 1377
  25.7.7. Mixture Model .............................................................................................. 1378
    25.7.7.1. Setting the Under-Relaxation Factor for the Slip Velocity ....................... 1378
    25.7.7.2. Calculating an Initial Solution .................................................................... 1378
    25.7.7.3. Discretization Scheme Selection for the Mixture Model ............................ 1378
  25.7.8. Eulerian Model ............................................................................................ 1378
    25.7.8.1. Calculating an Initial Solution ................................................................. 1378
    25.7.8.2. Temporarily Ignoring Lift and Virtual Mass Forces ................................ 1379
    25.7.8.3. Discretization Scheme Selection for the Implicit and Explicit Formulations .............................................................................................................................. 1379
    25.7.8.4. Using W-Cycle Multigrid .......................................................................... 1380
    25.7.8.5. Including the Anisotropic Drag Law ......................................................... 1380
  25.7.9. Wet Steam Model .......................................................................................... 1380
    25.7.9.1. Boundary Conditions, Initialization, and Patching .................................. 1380
    25.7.9.2. Solution Limits for the Wet Steam Model ................................................ 1381
    25.7.9.3. Solution Strategies for the Wet Steam Model .......................................... 1381
  25.8. Postprocessing for Multiphase Modeling ......................................................... 1382
  25.8.1. Model-Specific Variables .............................................................................. 1382
    25.8.1.1. VOF Model .............................................................................................. 1382
    25.8.1.2. Mixture Model ......................................................................................... 1382
    25.8.1.3. Eulerian Model ......................................................................................... 1383

  - 31.9.3.2.3. Changing the Legend Title .................................................. .............. 1703
- 31.9.3.3. Steps for Generating XY Plots of Data in External Files ............... 1701
- 31.9.3.4. Steps for Generating XY Plots of Profile Data ............................................. 1703
- 31.9.3.5. Steps for Generating an XY Plot of Circumferential Averages .......... 1705
- 31.9.3.6. Customizing the Appearance of the Plot ................................................. 1707
- 31.9.3.7. Using the Axes Dialog Box ................................................. ................................ 1710
- 31.9.3.8. Changing the Axis Label .................................................. ................................ 1710
- 31.9.3.9. Changing the Format of the Data Labels ................................................. 1710
- 31.9.3.10. Changing Logarithmic or Decimal Scaling ................................................. 1711
- 31.9.3.11. Resetting the Range of the Axis .................................................. ..................... 1711
- 31.9.3.12. Controlling the Major and Minor Rules ................................................. 1711

### 31.9.4. XY Plots of Profiles
- 31.9.4.1. Steps for Generating Plots of Profile Data ................................................. 1703
- 31.9.4.2. Steps for Generating Plots of Interpolated Profile Data ................. 1704

### 31.9.5. XY Plots of Circumferential Averages
- 31.9.5.1. Steps for Generating an XY Plot of Circumferential Averages .......... 1705
- 31.9.5.2. Customizing the Appearance of the Plot ................................................. 1707

### 31.9.6. XY Plot File Format

### 31.9.7. Residual Plots

### 31.9.8. Histograms
- 31.9.8.1. Steps for Generating Histogram Plots ................................................. 1708
- 31.9.8.2. Options for Histogram Plots .................................................. ...................... 1709
  - 31.9.8.2.1. Specifying the Range of Values Plotted ................................................. 1709

### 31.9.9. Modifying Axis Attributes
- 31.9.9.1. Using the Axes Dialog Box ................................................. ................................ 1710
  - 31.9.9.1.1. Changing the Axis Label .................................................. ......................... 1710
  - 31.9.9.1.2. Changing the Format of the Data Labels ................................................. 1710
  - 31.9.9.1.3. Choosing Logarithmic or Decimal Scaling ................................................. 1711
  - 31.9.9.1.4. Resetting the Range of the Axis .................................................. ..................... 1711
  - 31.9.9.1.5. Controlling the Major and Minor Rules ................................................. 1711
- 31.9.9.2. Changing the Axis Title .................................................. ................................... 1710
- 31.9.9.3. Choosing Logarithmic or Decimal Scaling ................................................. 1711
- 31.9.9.4. Resetting the Range of the Axis .................................................. ..................... 1711
- 31.9.9.5. Controlling the Major and Minor Rules ................................................. 1711

### 31.9.10. Modifying Curve Attributes
- 31.9.10.1. Using the Curves Dialog Box .................................................. .............. 1712
  - 31.9.10.1.1. Changing the Line Style .................................................. ................................ 1712
  - 31.9.10.1.2. Changing the Marker Style .................................................. ......................... 1713
  - 31.9.10.1.3. Previewing the Curve Style .................................................. .............. 1713
- 31.9.10.2. Changing the Line Style .................................................. ................................ 1712
- 31.9.10.3. Changing the Marker Style .................................................. ......................... 1713
- 31.9.10.4. Previewing the Curve Style .................................................. .............. 1713

### 31.10. Turbomachinery Postprocessing
- 31.10.1. Defining the Turbomachinery Topology ................................................. 1713
  - 31.10.1.1. Boundary Types .................................................. ........................... 1715
- 31.10.2. Generating Reports of Turbomachinery Data ................................................. 1717
  - 31.10.2.1. Computing Turbomachinery Quantities ................................................. 1718
    - 31.10.2.1.1. Mass Flow .................................................. ................................................... 1718
    - 31.10.2.1.2. Swirl Number .................................................. ................................................... 1718
    - 31.10.2.1.3. Average Total Pressure .................................................. ....................... 1718
    - 31.10.2.1.4. Average Total Temperature .................................................. ....................... 1719
    - 31.10.2.1.5. Average Flow Angles .................................................. ................................... 1719
    - 31.10.2.1.6. Passage Loss Coefficient .................................................. ....................... 1720
    - 31.10.2.1.7. Axial Force .................................................. ................................................... 1721
    - 31.10.2.1.8. Torque .................................................. ................................................... 1721
    - 31.10.2.1.9. Efficiencies for Pumps and Compressors ................................................. 1721
  - 31.10.2.2. Computing Turbomachinery Quantities ................................................. 1718
    - 31.10.2.2.1. Mass Flow .................................................. ................................................... 1718
    - 31.10.2.2.2. Swirl Number .................................................. ................................................... 1718
    - 31.10.2.2.3. Average Total Pressure .................................................. ....................... 1718
    - 31.10.2.2.4. Average Total Temperature .................................................. ....................... 1719
    - 31.10.2.2.5. Average Flow Angles .................................................. ................................... 1719
    - 31.10.2.2.6. Passage Loss Coefficient .................................................. ....................... 1720
    - 31.10.2.2.7. Axial Force .................................................. ................................................... 1721
    - 31.10.2.2.8. Torque .................................................. ................................................... 1721
    - 31.10.2.2.9. Efficiencies for Pumps and Compressors ................................................. 1721
31.11. Fast Fourier Transform (FFT) Postprocessing ................................................ 1731
31.11.1. Limitations of the FFT Algorithm ................................................................. 1731
31.11.2. Windowing .......................................................................................................... 1731
31.11.3. Fast Fourier Transform (FFT) ........................................................................... 1732
31.11.4. Using the FFT Utility .......................................................................................... 1734
31.11.4.1. Loading Data for Spectral Analysis ................................................................. 1734
31.11.4.2. Customizing the Input and Defining the Spectrum Smoothing ......................... 1735
31.11.4.2.1. Customizing the Input Signal Data Set ......................................................... 1735
31.11.4.2.2. Spectrum Smoothing Through Signal Segmentation .................................... 1736
31.11.4.2.3. Viewing Data Statistics .................................................................................. 1736
31.11.4.2.4. Customizing Titles and Labels ....................................................................... 1736
31.11.4.2.5. Applying the Changes in the Input Signal Data ............................................. 1736
31.11.4.3. Customizing the Output .................................................................................... 1737
31.11.4.3.1. Specifying a Function for the y-Axis ............................................................... 1737
31.11.4.3.2. Specifying a Function for the x-Axis ............................................................... 1739
31.11.4.3.3. Specifying Output Options ............................................................................ 1740
31.11.4.3.4. Specifying a Windowing Technique ............................................................... 1740
31.11.4.3.5. Specifying Labels and Titles ......................................................................... 1741

32. Reporting Alphanumeric Data .................................................................................. 1743
32.1. Reporting Conventions .......................................................................................... 1743
32.2. Creating Output Parameters .................................................................................. 1745
32.2.1. Computing Output Parameters With User-Defined Functions ............................. 1745
32.3. Fluxes Through Boundaries .................................................................................... 1746
32.3.1. Generating a Flux Report ...................................................................................... 1746
32.3.2. Flux Reporting for Reacting Flows ....................................................................... 1748
32.3.2.1. Flux Reporting with Particles ............................................................................ 1750
32.3.2.2. Flux Reporting with Multiphase ....................................................................... 1751
32.3.2.3. Flux Reporting with Other Volumetric Sources ............................................... 1751
32.4. Forces on Boundaries ............................................................................................. 1751
32.4.1. Generating a Force, Moment, or Center of Pressure Report ................................... 1751
32.4.1.1. Example ............................................................................................................... 1753
32.5. Projected Surface Area Calculations ........................................................................ 1755
32.6. Surface Integration ................................................................................................ 1755
32.6.1. Generating a Surface Integral Report ..................................................................... 1756
32.7. Volume Integration ................................................................................................ 1758
32.7.1. Generating a Volume Integral Report ..................................................................... 1758
32.8. Histogram Reports ................................................................................................ 1759
32.9. Discrete Phase .................................................................................................................. 1759
32.10. S2S Information ............................................................................................................. 1759
32.11. Reference Values .......................................................................................................... 1760
  32.11.1. Setting Reference Values .......................................................................................... 1760
  32.11.2. Setting the Reference Zone ...................................................................................... 1762
32.12. Summary Reports of Case Settings ............................................................................... 1762
  32.12.1. Generating a Summary Report .................................................................................. 1762
32.13. Memory and CPU Usage .............................................................................................. 1762

33. Field Function Definitions ............................................................................................... 1765
  33.1. Node, Cell, and Facet Values .......................................................................................... 1765
    33.1.1. Cell Values .............................................................................................................. 1765
    33.1.2. Node Values ............................................................................................................ 1765
      33.1.2.1. Vertex Values for Points That are Not Mesh Nodes ........................................... 1766
    33.1.3. Facet Values ............................................................................................................ 1766
      33.1.3.1. Facet Values on Zone Surfaces .......................................................................... 1766
      33.1.3.2. Facet Values on Postprocessing Surfaces ......................................................... 1767
  33.2. Velocity Reporting Options ........................................................................................... 1767
  33.3. Field Variables Listed by Category .............................................................................. 1768
  33.4. Alphabetical Listing of Field Variables and Their Definitions ..................................... 1787
  33.5. Custom Field Functions ............................................................................................... 1826
    33.5.1. Creating a Custom Field Function .......................................................................... 1827
      33.5.1.1. Using the Calculator Buttons .............................................................................. 1829
      33.5.1.2. Using the Field Functions List ............................................................................ 1829
    33.5.2. Manipulating, Saving, and Loading Custom Field Functions ................................ 1829
    33.5.3. Sample Custom Field Functions ............................................................................. 1830

34. Parallel Processing ............................................................................................................ 1833
  34.1. Introduction to Parallel Processing .............................................................................. 1833
    34.1.1. Recommended Usage of Parallel ANSYS Fluent ..................................................... 1835
  34.2. Starting Parallel ANSYS Fluent Using Fluent Launcher ............................................ 1836
    34.2.1. Setting Parallel Scheduler Options in Fluent Launcher ........................................... 1838
    34.2.2. Setting Additional Options When Running on Remote Linux Machines ............... 1841
      34.2.2.1. Setting Job Scheduler Options When Running on Remote Linux Machines ........ 1843
  34.3. Starting Parallel ANSYS Fluent on a Windows System ............................................ 1844
    34.3.1. Starting Parallel ANSYS Fluent on a Windows System Using Command Line Options 1844
      34.3.1.1. Starting Parallel ANSYS Fluent with the Microsoft Job Scheduler ..................... 1847
  34.4. Starting Parallel ANSYS Fluent on a Linux System .................................................. 1849

Using This Manual

This preface is divided into the following sections:

1. The Contents of This Manual
2. The Contents of the Fluent Manuals
3. Typographical Conventions
4. Mathematical Conventions
5. Technical Support

1. The Contents of This Manual

The ANSYS Fluent User's Guide tells you what you need to know to use ANSYS Fluent.

Important

Under U.S. and international copyright law, ANSYS, Inc. is unable to distribute copies of the papers listed in the bibliography, other than those published internally by ANSYS, Inc. Use your library or a document delivery service to obtain copies of copyrighted papers.

A brief description of what is in each chapter follows:

• Graphical User Interface (GUI) (p. 1), describes the mechanics of using the graphical user interface and the GUI on-line help.

• Text User Interface (TUI) (p. 29), describes the mechanics of using the text interface and the TUI on-line help. (See the Text Command List for information about specific text interface commands.)

• Reading and Writing Files (p. 41), describes the files that ANSYS Fluent can read and write, including picture files.

• Unit Systems (p. 109), describes how to use the standard and custom unit systems available in ANSYS Fluent.

• Reading and Manipulating Meshes (p. 113), describes the various sources of computational meshes and explains how to obtain diagnostic information about the mesh and how to modify it by scaling, translating, and other methods. This chapter also contains information about the use of non-conformal meshes.

• Cell Zone and Boundary Conditions (p. 201), describes the different types of boundary conditions available in ANSYS Fluent, when to use them, how to define them, and how to define boundary profiles and volumetric sources and fix the value of a variable in a particular region. It also contains information about porous media and lumped parameter models.

• Physical Properties (p. 397), describes the physical properties of materials and the equations that ANSYS Fluent uses to compute the properties from the information that you input.

• Modeling Basic Fluid Flow (p. 505), describes the governing equations and physical models used by ANSYS Fluent to compute fluid flow (including periodic flow, swirling and rotating flows, compressible flows, and inviscid flows), as well as the inputs you need to provide to use these models.

• Modeling Flows with Moving Reference Frames (p. 535), describes the use of single moving reference frames, multiple moving reference frames, and mixing planes in ANSYS Fluent.
• **Modeling Flows Using Sliding and Dynamic Meshes (p. 559)**, describes the use of sliding and deforming meshes in ANSYS Fluent.

• **Modeling Flows Using the Mesh Morpher/Optimizer (p. 673)**, describes the use of the mesh morphing capability in ANSYS Fluent that allows you to solve shape optimization problems [40] (p. 2559).

• **Modeling Turbulence (p. 695)**, describes the use of the turbulent flow models in ANSYS Fluent.

• **Modeling Heat Transfer (p. 759)**, describes the use of the physical models in ANSYS Fluent to compute heat transfer (including convective and conductive heat transfer, natural convection, radiative heat transfer, and periodic heat transfer), as well as the inputs you need to provide to use these models.

• **Modeling Heat Exchangers (p. 847)**, describes the use of the heat exchanger models in ANSYS Fluent.

• **Modeling Species Transport and Finite-Rate Chemistry (p. 885)**, describes the use of the finite-rate chemistry models in ANSYS Fluent. This chapter also provides information about modeling species transport in non-reacting flows.

• **Modeling Non-Premixed Combustion (p. 941)**, describes the use of the non-premixed combustion model in ANSYS Fluent. This chapter includes details about using prePDF.

• **Modeling Premixed Combustion (p. 1003)**, describes the use of the premixed combustion model in ANSYS Fluent.

• **Modeling Partially Premixed Combustion (p. 1013)**, describes the use of the partially premixed combustion model in ANSYS Fluent.

• **Modeling a Composition PDF Transport Problem (p. 1025)**, describes the use of the composition PDF transport model in ANSYS Fluent.

• **Using Chemistry Acceleration (p. 1039)**, describes the use of methods to accelerate computations for detailed chemical mechanisms involving laminar and turbulent flames.

• **Modeling Engine Ignition (p. 1051)**, describes the use of the engine ignition models in ANSYS Fluent.

• **Modeling Pollutant Formation (p. 1065)**, describes the use of the models for the formation of NOx, SOx, and soot in ANSYS Fluent.

• **Predicting Aerodynamically Generated Noise (p. 1111)**, describes the use of the acoustics model in ANSYS Fluent.

• **Modeling Discrete Phase (p. 1131)**, describes the use of the discrete phase models in ANSYS Fluent.

• **Modeling Multiphase Flows (p. 1243)**, describes the use of the general multiphase models in ANSYS Fluent (VOF, mixture, and Eulerian).

• **Modeling Solidification and Melting (p. 1389)**, describes the use of the solidification and melting model in ANSYS Fluent.

• **Modeling Eulerian Wall Films (p. 1397)**, describes the use of the Eulerian wall film model in ANSYS Fluent.

• **Using the Solver (p. 1405)**, describes the use of the ANSYS Fluent solvers.

• **Adapting the Mesh (p. 1545)**, describes the use of the solution-adaptive mesh refinement feature in ANSYS Fluent.
2. The Contents of the Fluent Manuals

The manuals listed below form the Fluent product documentation set. They include descriptions of the procedures, commands, and theoretical details needed to use Fluent products.

- **Fluent Getting Started Guide** contains general information about getting started with using Fluent and provides details about starting, running, and exiting the program.

- **Fluent Migration Manual** contains information about transitioning from the previous release of Fluent, including details about new features, solution changes, and text command list changes.

- **Fluent User's Guide** contains detailed information about running a simulation using the solution mode of Fluent, including information about the user interface, reading and writing files, defining boundary conditions, setting up physical models, calculating a solution, and analyzing your results.

- **ANSYS Fluent Meshing User's Guide** contains detailed information about creating 3D meshes using the meshing mode of Fluent.

- **Fluent in Workbench User's Guide** contains information about getting started with and using Fluent within the Workbench environment.

- **Fluent Theory Guide** contains reference information for how the physical models are implemented in Fluent.

- **Fluent UDF Manual** contains information about writing and using user-defined functions (UDFs).
• **Fluent Tutorial Guide** contains a number of examples of various flow problems with detailed instructions, commentary, and postprocessing of results.

• **ANSYS Fluent Meshing Tutorials** contains a number of examples of general mesh-generation techniques used in ANSYS Fluent Meshing.

  Tutorials for release 15.0 are available on the ANSYS Customer Portal. To access tutorials and their input files on the ANSYS Customer Portal, go to [http://support.ansys.com/training](http://support.ansys.com/training).

• **Fluent Text Command List** contains a brief description of each of the commands in Fluent’s solution mode text interface.

• **ANSYS Fluent Meshing Text Command List** contains a brief description of each of the commands in Fluent’s meshing mode text interface.

• **Fluent Adjoint Solver Module Manual** contains information about the background and usage of Fluent’s Adjoint Solver Module that allows you to obtain detailed sensitivity data for the performance of a fluid system.

• **Fluent Battery Module Manual** contains information about the background and usage of Fluent’s Battery Module that allows you to analyze the behavior of electric batteries.

• **Fluent Continuous Fiber Module Manual** contains information about the background and usage of Fluent’s Continuous Fiber Module that allows you to analyze the behavior of fiber flow, fiber properties, and coupling between fibers and the surrounding fluid due to the strong interaction that exists between the fibers and the surrounding gas.

• **Fluent Fuel Cell Modules Manual** contains information about the background and the usage of two separate add-on fuel cell models for Fluent that allow you to model polymer electrolyte membrane fuel cells (PEMFC), solid oxide fuel cells (SOFC), and electrolysis with Fluent.

• **Fluent Magnetohydrodynamics (MHD) Module Manual** contains information about the background and usage of Fluent’s Magnetohydrodynamics (MHD) Module that allows you to analyze the behavior of electrically conducting fluid flow under the influence of constant (DC) or oscillating (AC) electromagnetic fields.

• **Fluent Population Balance Module Manual** contains information about the background and usage of Fluent’s Population Balance Module that allows you to analyze multiphase flows involving size distributions where particle population (as well as momentum, mass, and energy) require a balance equation.

• **Fluent as a Server User’s Guide** contains information about the usage of Fluent as a Server which allows you to connect to a Fluent session and issue commands from a remote client application.

• **Running Fluent Under LSF** contains information about using Fluent with Platform Computing’s LSF software, a distributed computing resource management tool.

• **Running Fluent Under PBS Professional** contains information about using Fluent with Altair PBS Professional, an open workload management tool for local and distributed environments.

• **Running Fluent Under SGE** contains information about using Fluent with Sun Grid Engine (SGE) software, a distributed computing resource management tool.
3. Typographical Conventions

Several typographical conventions are used in this manual’s text to facilitate your learning process.

- Different type styles are used to indicate graphical user interface menu items and text interface menu items (for example, Iso-Surface dialog box, surface/iso-surface command).

- The text interface type style is also used when illustrating exactly what appears on the screen to distinguish it from the narrative text. In this context, user inputs are typically shown in boldface.

- A mini flow chart is used to guide you through the navigation pane, which leads you to a specific task page or dialog box. For example,

  ![Flow Chart]

  Models → Multiphase → Edit...

  indicates that Models is selected in the navigation pane, which then opens the corresponding task page. In the Models task page, Multiphase is selected from the list. Clicking the Edit... button opens the Multiphase dialog box.

  Also, a mini flow chart is used to indicate the menu selections that lead you to a specific command or dialog box. For example,

  Define → Injections...

  indicates that the Injections... menu item can be selected from the Define pull-down menu, and

  display → mesh

  indicates that the mesh command is available in the display text menu.

In this manual, mini flow charts usually precede a description of a dialog box or command, or a screen illustration showing how to use the dialog box or command. They allow you to look up information about a command or dialog box and quickly determine how to access it without having to search the preceding material.

- The menu selections that will lead you to a particular dialog box or task page are also indicated (usually within a paragraph) using a "/". For example, Define/Materials... tells you to choose the Materials... menu item from the Define pull-down menu.

4. Mathematical Conventions

- Where possible, vector quantities are displayed with a raised arrow (e.g., \( \vec{a}, \vec{A} \)). Boldfaced characters are reserved for vectors and matrices as they apply to linear algebra (e.g., the identity matrix, \( I \)).

- The operator \( \nabla \), referred to as grad, nabla, or del, represents the partial derivative of a quantity with respect to all directions in the chosen coordinate system. In Cartesian coordinates, \( \nabla \) is defined to be

\[
\frac{\partial}{\partial x} \hat{i} + \frac{\partial}{\partial y} \hat{j} + \frac{\partial}{\partial z} \hat{k}
\]  

(1)

\( \nabla \) appears in several ways:

- The gradient of a scalar quantity is the vector whose components are the partial derivatives; for example,
\[ \nabla p = \frac{\partial p}{\partial x} \hat{i} + \frac{\partial p}{\partial y} \hat{j} + \frac{\partial p}{\partial z} \hat{k} \]  

(2)

- The gradient of a vector quantity is a second-order tensor; for example, in Cartesian coordinates,

\[ \nabla (\vec{v}) = \left( \frac{\partial}{\partial x} \vec{r} + \frac{\partial}{\partial y} \vec{J} + \frac{\partial}{\partial z} \vec{K} \right) \left( v_x \hat{i} + v_y \hat{j} + v_z \hat{k} \right) \]  

(3)

This tensor is usually written as

\[
\begin{pmatrix}
\frac{\partial v_x}{\partial x} & \frac{\partial v_y}{\partial x} & \frac{\partial v_z}{\partial x} \\
\frac{\partial v_x}{\partial y} & \frac{\partial v_y}{\partial y} & \frac{\partial v_z}{\partial y} \\
\frac{\partial v_x}{\partial z} & \frac{\partial v_y}{\partial z} & \frac{\partial v_z}{\partial z}
\end{pmatrix}
\]  

(4)

- The divergence of a vector quantity, which is the inner product between \( \nabla \) and a vector; for example,

\[ \nabla \cdot \vec{v} = \frac{\partial v_x}{\partial x} + \frac{\partial v_y}{\partial y} + \frac{\partial v_z}{\partial z} \]  

(5)

- The operator \( \nabla \cdot \nabla \), which is usually written as \( \nabla^2 \) and is known as the Laplacian; for example,

\[ \nabla^2 T = \frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} + \frac{\partial^2 T}{\partial z^2} \]  

(6)

\( \nabla^2 T \) is different from the expression \( (\nabla T)^2 \), which is defined as

\[ (\nabla T)^2 = \left( \frac{\partial T}{\partial x} \right)^2 + \left( \frac{\partial T}{\partial y} \right)^2 + \left( \frac{\partial T}{\partial z} \right)^2 \]  

(7)

- An exception to the use of \( \nabla \) is found in the discussion of Reynolds stresses in Turbulence in the Fluent Theory Guide, where convention dictates the use of Cartesian tensor notation. In this chapter, you will also find that some velocity vector components are written as \( u, v, \) and \( w \) instead of the conventional \( v \) with directional subscripts.

5. Technical Support

If you encounter difficulties while using ANSYS Fluent, please first refer to the section(s) of the manual containing information on the commands you are trying to use or the type of problem you are trying to solve. The product documentation is available from the online help, or from the ANSYS Customer Portal. To access documentation files on the ANSYS Customer Portal, go to http://support.ansys.com/documentation.
If you encounter an error, please write down the exact error message that appeared and note as much information as you can about what you were doing in ANSYS Fluent.

Technical Support for ANSYS, Inc. products is provided either by ANSYS, Inc. directly or by one of our certified ANSYS Support Providers. Please check with the ANSYS Support Coordinator (ASC) at your company to determine who provides support for your company, or go to www.ansys.com and select Contact ANSYS > Contacts and Locations.

If your support is provided by ANSYS, Inc. directly, Technical Support can be accessed quickly and efficiently from the ANSYS Customer Portal, which is available from the ANSYS Website (www.ansys.com) under Support > Customer Portal. The direct URL is: support.ansys.com.

One of the many useful features of the Customer Portal is the Knowledge Resources Search, which can be found on the Home page of the Customer Portal.

Systems and installation Knowledge Resources are easily accessible via the Customer Portal by using the following keywords in the search box: Systems/Installation. These Knowledge Resources provide solutions and guidance on how to resolve installation and licensing issues quickly.

Chapter 1: Graphical User Interface (GUI)

The ANSYS Fluent graphical interface consists of a menu bar to access the menus, a toolbar, a navigation pane, a task page, a graphics toolbar, graphics windows, and a console, which is a textual command line interface (described in Text User Interface (TUI) (p. 29)). You will also have access to the dialog boxes via the task page or the menus.

1.1. GUI Components
1.2. Customizing the Graphical User Interface (Linux Systems Only)
1.3. Using the GUI Help System

1.1. GUI Components

The graphical user interface (GUI) is made up of seven main components, which are described in detail in the subsequent sections: the menu bar, toolbars, a navigation pane, task pages, a console, dialog boxes, and graphics windows. When you use the GUI, you will be interacting with one of these components at all times. The GUI will change depending on whether you are in meshing mode (as described in the Fluent Meshing User’s Guide) or solution mode (as described in this guide, and as shown in Figure 1.1: The GUI Components (p. 2)). For details on how to switch between these modes, see Switching Between Meshing and Solution Modes in the Getting Started Guide.

On Linux systems, the attributes of the GUI (including colors and text fonts) can be customized to better match your platform environment. This is described in Customizing the Graphical User Interface (Linux Systems Only) (p. 23).
Figure 1.1: The GUI Components

For additional information, see the following sections:

1.1.1. The Menu Bar
1.1.2. Toolbars
1.1.3. The Navigation Pane
1.1.4. Task Pages
1.1.5. The Console
1.1.6. Dialog Boxes
1.1.7. Graphics Windows

1.1.1. The Menu Bar

The menu bar organizes the GUI menu hierarchy using a set of pull-down menus. A pull-down menu contains items that perform commonly executed actions. Figure 1.2: The ANSYS Fluent Menu Bar (p. 3) shows the ANSYS Fluent menu bar for solution mode (for details on the meshing mode menu bar, see the Fluent Meshing User’s Guide). Menu items are arranged to correspond to the typical sequence of actions that you perform in ANSYS Fluent (that is, from left to right and from top to bottom).
To select a pull-down menu item with the mouse, follow the procedure outlined below:

1. Move the pointer to the name of the pull-down menu.
2. Click the left mouse button to display the pull-down menu.
3. Move the pointer to the item you want to select and click it.

In addition to using the mouse, you can also select a pull-down menu item using the keyboard. If you press the **Alt** key, each pull-down menu label or menu item will display one underlined character, known as the mnemonic. If you then press the mnemonic character of a pull-down menu on the keyboard, the associated menu will be displayed (note that the mnemonic character is not case sensitive). After the pull-down menu is selected and displayed, you can type a mnemonic character associated with an item to select that item. For example, to display the **Help** menu and select the **Using Help...** option, press **Alt**, then **h**, and then **h** again. If at any time you want to cancel a menu selection while a pull-down menu is displayed, you can press the **Esc** key.

### 1.1.2. Toolbars

The ANSYS Fluent GUI includes toolbars located within the application window. These toolbars provide shortcuts to performing common tasks in ANSYS Fluent. By default, the toolbars are docked to the ANSYS Fluent interface but can also be detached and moved to a new location. You can detach a toolbar by clicking the left mouse button on the outer portion of it, holding down the mouse, and dragging the toolbar to a new location. To move the detached toolbar, select the title bar and drag the toolbar to a new position in the application window. Once detached, the toolbars can be restored to their location in the interface by double-clicking the title region of the toolbar.

**Important**

Toolbars that are detached or moved to a new location will return to their original positions each time ANSYS Fluent is launched.

The small arrow button attached to some buttons in the toolbars can be used to access additional functionality in ANSYS Fluent. For instance, there are additional selections available when you click the small arrow attached to the **Read a file** button in the standard toolbar.

The ANSYS Fluent graphical user interface includes a mode toolbar, a standard toolbar, and a graphics toolbar.

#### 1.1.2.1. The Mode Toolbar

The mode toolbar contains the **Switch to Solution** button ( ). This button allows you to switch from meshing mode to solution mode, as described in **Switching Between Meshing and Solution Modes** in the **Getting Started Guide**. It is not available when you are in solution mode.
1.1.2.2. **The Standard Toolbar**

The standard toolbar (Figure 1.3: The Standard Toolbar (p. 4)) contains options for working with ANSYS Fluent case files, saving images, and accessing the ANSYS Fluent documentation.

**Figure 1.3: The Standard Toolbar**

The following is a brief description of each of the standard toolbar options.

- **Read a file** allows you to read in a mesh, open existing ANSYS Fluent case files, and other file types using a file selection dialog box. Here, you can browse through your collection of directories, and locate a file. For more information, see *Reading and Writing Case and Data Files (p. 47)*.

- **Write a file** saves the current ANSYS Fluent case, data, or other file types. For more information, see *Reading and Writing Case and Data Files (p. 47)*.

- **Save Picture** allows you to capture an image of the active graphics window. For more information, see *Saving Picture Files (p. 102)*.

- **Help** allows you to access the ANSYS Fluent User's Guide for help topics. For more information, see *Using the GUI Help System (p. 24)*.

1.1.2.3. **The Graphics Toolbar**

The graphics toolbar (Figure 1.4: The Graphics Toolbar (p. 4)) contains options that enable you to modify the way in which you view your model or select objects in the graphics window.

**Figure 1.4: The Graphics Toolbar**

The following is a description of each of the graphics toolbar options.

- **Rotate View** lets you rotate your model about a central point in the graphics window. For more information, see *Button Functions (p. 1654)*.

- **Pan** allows you to pan horizontally or vertically across the view using the left mouse button. For more information, see *Button Functions (p. 1654)*.
• **Zoom In/Out** allows you to zoom in to and out of the model by holding the left mouse button down and moving the mouse down or up. For more information, see Button Functions (p. 1654). You can also roll the view by holding the left mouse button down and moving the mouse left or right.

• **Zoom to Area** allows you to focus on any part of your model. After selecting this option, position the mouse pointer at a corner of the area to be magnified, hold down the left mouse button and drag open a box to the desired size, and then release the mouse button. The enclosed area will then fill the graphics window. Note that you must drag the mouse to the right in order to zoom in. To zoom out, you must drag the mouse to the left. For more information, see Button Functions (p. 1654).

• **Print information about selected item** allows you to select items from the graphics windows and request information about displayed scenes. This behaves as a mouse probe button. For more information, see Button Functions (p. 1654).

• **Fit to Window** adjusts the overall size of your model to take maximum advantage of the graphics window’s width and height.

• **Isometric view** contains a drop-down of views, allowing you to display the model from the direction of the vector equidistant to all three axes, as well as in different axes orientations.

• **Arrange the workspace** provides you with several application window layout options. For example, you can choose to hide certain windows, or view multiple graphics windows. This is essentially the shortcut to the View menu. For information about the various layouts, see Viewing the Application Window (p. 1656).

• **Arrange the graphics window layout** allows you to specify the number and layout of the graphics windows, when they are embedded in the ANSYS Fluent application window. You can have up to four graphics window embedded at one time. This is essentially a shortcut to the View/Graphics Window Layout menu. See Viewing the Application Window (p. 1656) for further details.

### 1.1.2.4. The Objects Toolbar

The Objects toolbar (Figure 1.5: The Objects Toolbar (p. 5)) contains options for the display of Faces and Objects in the graphics window.

**Figure 1.5: The Objects Toolbar**

The following is a brief description of each of the Objects toolbar options.

• **Faces Options** contains options for displaying face zones in the graphics window.
- **All**
  
  draws all faces in the face zone(s) selected in the Display Grid Dialog Box, colored by their zone type.

- **Free**
  
  draws free faces (faces with no neighboring face on at least one edge) on the face zone(s) selected in the Display Grid Dialog Box.

- **Multi**
  
  draws multiply-connected faces on the face zone(s) selected in the Display Grid Dialog Box, along with their nodes. A multiply-connected face is a boundary face that shares an edge with more than one other face, while a multiply-connected node is a node that is on a multiply-connected edge (an edge that is shared by more than two boundary faces).

- **Objects Options**

  contains options for displaying objects in the graphics window.

  - **Draw Face Zones**
    
    displays the face zone(s) comprising the object(s) drawn in the graphics window.

  - **Draw Edge Zones**
    
    displays the edge zone(s) comprising the object(s) drawn in the graphics window.

### 1.1.3. The Navigation Pane

The navigation pane, located on the left side of the ANSYS Fluent GUI, contains a list of task pages, as shown in Figure 1.6: The ANSYS Fluent Navigation Pane (p. 7).
The list consists of a **Meshing** section, **Solution Setup** task pages, **Solution**-related activities, and a **Results** section for postprocessing.

When any of the items under **Meshing**, **Solution Setup**, **Solution**, or **Results** is highlighted, the task page (Task Pages (p. 8)) will be displayed to the right of the navigation pane. The items in the navigation pane are listed in the order in which you would normally set up, solve, and postprocess a case.

Using the navigation pane is an alternative to using the menu bar. For example, there are two ways you can access the **Viscous Model** dialog box (see Viscous Model Dialog Box (p. 1903)). To access it using the navigation pane, highlight **Models** in the navigation pane by clicking it with your left mouse button. The **Models** task page (see Models Task Page (p. 1896)) will appear to the right of the navigation pane. Select **Viscous** from the **Models** list and click the **Edit...** button (or simply double-click **Viscous**) to open the **Viscous Model** dialog box (see Viscous Model Dialog Box (p. 1903)).

![Models → Viscous → Edit...](image)

You can also access the **Viscous Model** dialog box (see Viscous Model Dialog Box (p. 1903)) using the following menu path:

**Define → Models...**

This will open the **Models** task page (see Models Task Page (p. 1896)), where you will select **Viscous** from the **Models** list and click the **Edit...** button (or simply double-click **Viscous**) to open the **Viscous Model** dialog box (see Viscous Model Dialog Box (p. 1903)).

Note that while most of the task pages can be accessed using the navigation pane, there are some dialog boxes that can only be accessed using the menu path. For example, to access the **Custom Field**...
Function Calculator dialog box (see Custom Field Function Calculator Dialog Box (p. 2448)), use the following menu path:

Define → Custom Field Functions...

1.1.4. Task Pages

Task pages appear on the right side of the navigation pane when an item is highlighted in the navigation pane (see Figure 1.1: The GUI Components (p. 2)). The expected workflow is that you travel down the navigation pane, setting the controls provided in each task page until you are ready to run the calculation. Note that you can access the task pages through the menu items, as described in the example in The Navigation Pane (p. 6).

Some of your setup will occur in dialog boxes, while others in task pages. For example, if General is selected in the navigation pane, this task page is displayed. Global settings are made in this task page, which are saved to the case definition.

Each task page has a Help button. Clicking this button opens the related help topic in the Reference Guide. See Using the GUI Help System (p. 24) for more information.

1.1.5. The Console

The console is located below the graphics window, as shown in Figure 1.1: The GUI Components (p. 2). ANSYS Fluent communicates with you through the console. It is used to display various kinds of information (that is, messages relating to meshing or solution procedures, etc.). ANSYS Fluent saves a certain amount of information that is written to the console into memory. You can review this information at any time by using the scroll bar on the right side of the console. The size of the console can be adjusted by raising or lowering the bottom frame of the graphics window.

The console is similar in behavior to “xterm” or other Linux command shell tools, or to the MS-DOS Command Prompt window on Windows systems. It allows you to interact with the TUI menu. More information on the TUI can be found in Text User Interface (TUI) (p. 29).

The console accepts a “break” command (pressing Ctrl+c at the same time) to let you interrupt the program while it is working. It also lets you perform text copy and paste operations between the console and other X Window (or Windows) applications that support copy and paste. The following steps show you how to perform a copy and paste operation on a Windows system:

1. Move the pointer to the beginning of the text to be copied.
2. Press and hold down the left mouse button.
3. Move the pointer to the end of the text (text should be highlighted).
4. Release the left mouse button.
5. Press the Ctrl and <Insert> keys at the same time.
6. Move the pointer to the target window and click the left mouse button.
7. Press the Ctrl+v keys at the same time.

On a Linux system, you will follow the steps below to copy text to the clipboard:

1. Move the pointer to the beginning of the text to be copied.
2. Press and hold down the left mouse button.

3. Move the pointer to the end of the text (text should be highlighted).

4. Release the left mouse button.

5. Move the pointer to the target window.

6. Press the middle mouse button to “paste” the text.

### 1.1.6. Dialog Boxes

There are two types of dialog boxes in ANSYS Fluent. Some dialog boxes are used to perform simple input/output tasks, such as issuing warning and error messages, or asking a question requiring a yes or no answer. Other forms of dialog boxes allow you to perform more complicated input tasks.

A dialog box is a separate “temporary” window that appears when ANSYS Fluent needs to communicate with you, or when various types of input controls are employed to set up your case. The types of controls you will see are described further in this section.

When you have finished entering data in a dialog box’s controls, you must apply the changes you have made, or cancel the changes, if desired. For this task, each dialog box falls into one of two behavioral categories, depending on how it was designed.

The first category of dialog boxes is used in situations where it is desirable to apply the changes and immediately close the dialog box. This type of dialog box includes an **OK** and a **Cancel** button which function as described below:

**OK**
- applies any changes you have made to the dialog box, then closes the dialog box.

**Cancel**
- closes the dialog box, ignoring any changes you have made.

An example of this type of dialog box is shown in the following figure:

![Mouse Buttons](image)

The other category of dialog boxes is used in situations where it is desirable to keep the dialog box displayed on the screen after changes have been applied. This makes it easy to quickly go back to that dialog box and make more changes. Dialog boxes used for postprocessing and mesh adaption often fall into this category. This type of dialog box typically includes an **Apply** button and a **Close** button as described below:
Apply
appllies any changes you have made to the dialog box, but does not close the dialog box. The name of this button is often changed to something more descriptive. For example, many of the postprocessing dialog boxes use the name Display for this button, and the adaption dialog boxes use the name Adapt.

Close
closes the dialog box.

An example of this type of dialog box is shown in the following figure:

![Mesh Display Dialog Box]

All dialog boxes include the following button used to access ANSYS Help:

Help
displays information about the controls in the dialog box. The help information will appear in the ANSYS Help Viewer.

Many dialog boxes also present additional buttons to accomplish specific tasks or open additional dialog boxes. You can find descriptions of the functions of these additional buttons in Menu Reference Guide (p. 2375) or Task Page Reference Guide (p. 1887) depending on whether the dialog box is accessed from the Menu Bar or from a Task Page.

1.1.6.1. Input Controls

Each type of input control utilized by the dialog boxes is described below. Note that the examples shown here are for a Windows system; if you are working on a Linux system, your dialog box controls may look slightly different, but they will work exactly as described here.

1.1.6.1.1. Tabs

Much like the tabs on a notebook divider, tabs in dialog boxes are used to mark the different sections into which a dialog box is divided. A dialog box that contains many controls may be divided into different sections to reduce the amount of screen space it occupies. You can access each section of the dialog
box by “clicking” the left mouse button on the corresponding tab. A click is one press and release of the mouse button.

1.1.6.1.2. Buttons

A button, also referred to as a push button, is used to perform a function indicated by the button label. To activate a button, place the pointer over the button and click the left mouse button.

1.1.6.1.3. Check Boxes

A check box, also referred to as a check button, is used to enable / disable an item or action indicated by the check box label. Click the left mouse button on the check box to toggle the state.

1.1.6.1.4. Radio Buttons

Radio buttons are a set of check boxes with the condition that only one can be set in the “on” position at a time. When you click the left mouse button on a radio button, it will be turned on, and all others will be turned off. Radio buttons appear either as diamonds (in Linux systems) or as circles (as shown above).

1.1.6.1.5. Text Entry Boxes

A text entry box lets you type text input. It will often have a label associated with it to indicate the purpose of the entry.

1.1.6.1.6. Integer Number Entry Boxes

An integer number entry box is similar to a text entry except it only allows integer numbers to be entered (for example, 10, -10, 50000 and 5E4). You may find it easier to enter large integer numbers using scientific notation. For example, you could enter $3.5E5$.

The integer number entry also has arrow buttons that allow you to easily increase or decrease its value. For most integer number entry controls, the value will be increased (or decreased) by one when you click an arrow button. You can increase the size of the increment by holding down a keyboard key while clicking the arrow button. The keys used are shown below:

<table>
<thead>
<tr>
<th>Key</th>
<th>Factor of Increase</th>
</tr>
</thead>
<tbody>
<tr>
<td>Shift</td>
<td>10</td>
</tr>
<tr>
<td>Ctrl</td>
<td>100</td>
</tr>
</tbody>
</table>
1.1.6.1.7. Real Number Entry Boxes

A real number entry box is similar to a text entry, except it only allows real numbers to be entered (for example, 10, -10.538, 50000.45 and 5.72E-4). In most cases, the label will show the units associated with the real number entry.

1.1.6.1.8. Single-Selection Lists

A single-selection list presents a list of items, with each item printed on a separate line. You can select an item by placing the pointer over the item line and clicking with the left mouse button. The selected item will become highlighted. Selecting another item will deselect the previously selected item in the list.

Many dialog boxes will also accept a double-click in order to invoke the dialog box action that is associated with the list selection (see information on the dialog box of interest for more details).

1.1.6.1.9. Multiple-Selection Lists

A multiple-selection list is similar to a single-selection list, except it allows for more than one selected item at a time. When you click the left mouse button on an item, its selection state will toggle. Clicking an unselected item will select it. Clicking a selected item will deselect it.

To select a range of items in a multiple-selection list, you can select the first desired item, and then select the last desired item while holding down the Shift key. The first and last items, and all the items between them, will be selected. You can also click and drag the left mouse button to select multiple items.

There are several small buttons in the upper right corner of the multiple selection list to accelerate selecting or deselecting items from the selection list.

- Click  to toggle a tree view for items listed in the selection list. In this view, the items that share a common prefix are grouped together under the prefix. The tree branches are collapsed by default—a plus
sign is (+) used to indicate this. Use Ctrl + left mouse button to expand or collapse the list. The numbers shown next to the prefix indicate the number of items in the group and the number of items that are selected, respectively. For example, +board-[3, 1] indicates that the selection list comprises 3 surfaces prefixed with board- of which 1 is currently selected. You can select or deselect all the items in a group by left clicking the prefix (regardless of whether the list is expanded or collapsed).

- Click  to select all the items in the selection list.
- Click  to deselect all the items in the selection list.

### 1.1.6.1.10. Drop-Down Lists

<table>
<thead>
<tr>
<th>Scheme</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIMPLE</td>
</tr>
<tr>
<td>SIMPLE</td>
</tr>
<tr>
<td>SIMPLEC</td>
</tr>
<tr>
<td>PISO</td>
</tr>
<tr>
<td>Coupled</td>
</tr>
</tbody>
</table>

A drop-down list is a hidden single-selection list that shows only the current selection to save space. When you want to change the selection, follow the steps below:

1. Click the arrow button to display the list.
2. Place the pointer over the new list item.
3. Click the left mouse button on the item to make the selection and close the list.

If you want to abort the selection operation while the list is displayed, you can move the pointer anywhere outside the list and click the left mouse button.

### 1.1.6.1.11. Scales

| 127 | Green |

A scale is used to select a value from a predefined range by moving a slider. The number shows the current value. You can change the value by clicking the arrow buttons, or by following one of the procedures below:

1. Place the pointer over the slider.
2. Press and hold down the left mouse button.
3. Move the pointer along the slider bar to change the value.
4. Release the left mouse button.

or

1. Place the pointer over the slider and click the left mouse button.
2. Using the arrow keys on the keyboard, move the slider bar left or right to change the value.
1.1.6.2. Types of Dialog Boxes

The following sections describe the various types of dialog boxes.

1.1.6.2.1. Information Dialog Boxes

The Information dialog box is used to report some information that ANSYS Fluent thinks you should know. After you have read the information, you can click the OK button to close the dialog box.

1.1.6.2.2. Warning Dialog Boxes

The Warning dialog box is used to warn you of a potential problem or deliver an important message. Your control of ANSYS Fluent will be suspended until you acknowledge the warning by clicking the OK button.

1.1.6.2.3. Error Dialog Boxes

The Error dialog box is used to alert you of an error that has occurred. After you have read the error information, you can click the OK button to close the dialog box.

1.1.6.2.4. The Working Dialog Box
The **Working** dialog box is displayed when ANSYS Fluent is busy performing a task. This is a special dialog box, because it requires no action by you. It is there to let you know that you must wait. When the program is finished, it will close the dialog box automatically. You can, however, abort the task that is being performed by clicking the **Cancel** button.

### 1.1.6.2.5. Question Dialog Box

![Question Dialog Box](Figure 1.7: The Select File Dialog Box for Windows (p. 16))

The **Question** dialog box is used to ask you a question. Sometimes the question will require a **Yes** or **No** answer, while other times it will require that you either allow an action to proceed (**OK**) or **Cancel** the action. You can click the appropriate button to answer the question.

### 1.1.6.2.6. The Select File Dialog Box

File selection is accomplished using the **Select File** dialog box ([The Select File Dialog Box (Windows)](p. 15) or [The Select File Dialog Box (Linux)](p. 16)).

#### 1.1.6.2.6.1. The Select File Dialog Box (Windows)

File selection on Windows systems is accomplished using the standard Windows **Select File** dialog box (Figure 1.7: The Select File Dialog Box for Windows (p. 16)).
See documentation regarding your Windows system for further instructions on file selection.

**1.1.6.2.6.2. The Select File Dialog Box (Linux)**

For Linux systems, note that the appearance of the **Select File** dialog box will not always be the same.

The version shown in Figure 1.8: The Select File Dialog Box for Linux Platforms (p. 17) will appear in almost all cases, but it will be different if you are loading external data files for use in an XY plot (see Including External Data in the Solution XY Plot (p. 1701) for more information). In such cases, the dialog box will look like Figure 1.9: Another Version of the Select File Dialog Box for Linux Platforms (p. 18).
Figure 1.8: The Select File Dialog Box for Linux Platforms

![Select File Dialog Box](image)

- **Filter**: `/home/user/tutorial/*.{cas,msh,MSH}`
- **Directories**:
  - `/home/kot/home/user/tutorial/`
  - `/home/kot/home/user/tutorial/..
- **Files**:
  - `cavity.cas`
- **Options**:
  - Display Mesh after Reading
- **Case File**: `/home/user/tutorial/cavity.cas`
- **Buttons**: OK, Filter, Cancel
The steps for file selection are as follows:

1. Go to the appropriate directory. You can do this in two different ways:
   - Enter the path to the desired directory in the Filter text entry box and then press the Enter key or click the Filter button. Be sure to include the final / character in the pathname, before the optional search pattern (described below).
   - Double-click a directory, and then a subdirectory, etc. in the Directories list until you reach the directory you want. You can also click once on a directory and then click the Filter button, instead of double-clicking. Note that the ".." item represents the current directory and the "..." item represents the parent directory.

2. Specify the file name by selecting it in the Files list or entering it in the File text entry box (if available) at the bottom of the dialog box. The name of this text entry box will change depending on the type of file you are selecting (Case File, Journal File, etc.).

   **Important**

   Note that if you are searching for an existing file with a nonstandard extension, you may need to modify the “search pattern” at the end of the path in the Filter text entry box.
For example, if you are reading a data file, the default extension in the search path will be * .dat *, and only those files that have a . dat extension will appear in the Files list. If you want files with a .DAT extension to appear in the Files list, you can change the search pattern to * .DAT*. If you want all files in the directory to be listed in the Files list, enter just * as the search pattern.

3. If you are reading a mesh or case file, use the Display Mesh after Reading option to specify whether you want ANSYS Fluent to automatically display the mesh after the file is read. All of the boundary zones will be displayed, except for the interior zones of 3D geometries. The default status of this option (that is, enabled or disabled) is determined by your decision regarding the Display Mesh After Reading option in Fluent Launcher.

4. If you using the Mesh/Replace... menu item to replace a mesh for which data exists, you can enable the Interpolate Data Across Zones option to interpolate the data across cell zones. This option is appropriate when the matching zone pairs (that is, the zones with the same names in both the current mesh and the replacement mesh) do not have the same interior zone boundaries. See Replacing the Mesh (p. 191) for details.

5. If you are reading multiple XY-plot data files, the selected file will be added to the list of XY File(s). You can choose another file, following the instructions above, and it will also be added to this list. (If you accidentally select the wrong file, you can choose it in the XY File(s) list and click the Remove button to remove it from the list of files to be read.) Repeat until all of the desired files are in the XY File(s) list.

6. If you are writing a case, data, or radiation file, use the Write Binary Files check box to specify whether the file should be written as a text or binary file. You can read and edit a text file, but it will require more storage space than the same file in binary format. Binary files take up less space and can be read and written by ANSYS Fluent more quickly.

7. Click the OK button to read or write the specified file. Shortcuts for this step are as follows:

   • If your file appears in the Files list and you are not reading an XY file, double-click it instead of just selecting it. This will automatically activate the OK button. (If you are reading an XY file, you will always have to click OK yourself. Clicking or double-clicking will just add the selected file to the XY File(s) list.)

   • If you entered the name of the file in the File text entry box, you can press the Enter key instead of clicking the OK button.

1.1.7. Graphics Windows

Graphics windows display the program’s graphical output, and may be viewed within the ANSYS Fluent application window or in separate windows. The decision to embed the graphics window or to have floating graphics windows is made when you start ANSYS Fluent using Fluent Launcher. For information about Fluent Launcher, refer to Setting General Options in Fluent Launcher in the Getting Started Guide. When viewed within the application window, the graphics windows will be placed below the toolbar on the right, as shown in Figure 1.1: The GUI Components (p. 2).
In Figure 1.10: Displaying Two Graphics Windows (p. 20), two graphics windows are displayed by selecting the menu item View/Graphics Window Layout, then selecting . Although this setup only allows two windows to be visible at a given time, any number of graphics windows can be created. You can select any existing graphics window to be displayed in either location through the drop-down menu, which appears in the top left corner of the embedded graphics window. This drop-down displays the title of the window.

**Important**

You can change the text that appears in the graphics window title section by simply clicking in the area and editing it as you would in a text editor.

The Display Options dialog box (see Display Options Dialog Box (p. 2314)) can be used to change the attributes of the graphics window or to open another graphics window. The Mouse Buttons dialog box (see Mouse Buttons Dialog Box (p. 2503)) can be used to set the action taken when a mouse button is pressed in the graphics window.

**Important**

To cancel a display operation, press Ctrl+c while the data is being processed in preparation for graphical display. You cannot cancel the operation after the program begins to draw in the graphics window.
For Windows systems, there are special features for printing the contents of the graphics window directly. These features are not available on Linux systems.

### 1.1.7.1. Printing the Contents of the Graphics Window (Windows Systems Only)

If you are using the Windows version of ANSYS Fluent with free floating graphics windows (that is, they are not embedded in the application window), you can display the graphics window's system menu by right-clicking in the uppermost portion of the graphics window. This menu contains the usual system commands, such as move, size, and close. Along with the system commands, ANSYS Fluent includes three commands in the menu for printer and clipboard support (these three commands are also available for embedded graphics windows). These commands are described below:

**Page Setup...**
- displays the Page Setup dialog box, which allows you to change attributes of the picture copied to the clipboard, or sent to a printer. Further details about this dialog box are included in the following section.

**Print...**
- displays the Microsoft Windows Print dialog box (see Printing the Contents of the Graphics Window (Windows Systems Only) (p. 21)), which enables you to send a copy of the picture to a printer. Some attributes of the copied picture can be changed using the Page Setup dialog box (see Using the Page Setup Dialog Box (Windows Systems Only) (p. 21)). Still more attributes of the final print can be specified within the Microsoft Windows Print and Print Setup dialog boxes (see documentation for Microsoft Windows and your printer for details).

**Copy to Clipboard**
- places a copy of the current picture into the Microsoft Windows clipboard. Some attributes of the copied picture can be changed using the Page Setup dialog box (see Figure 1.11: The Page Setup Dialog Box (Windows Systems Only) (p. 22)). The size of your graphics window affects the size of the text fonts used in the picture. For best results, experiment with the graphics window size and examine the resulting clipboard picture using the Windows clipboard viewer.

### 1.1.7.2. Using the Page Setup Dialog Box (Windows Systems Only)

To open the Page Setup dialog box (Figure 1.11: The Page Setup Dialog Box (Windows Systems Only) (p. 22)), select the Page Setup... menu item in the system menu of the graphics window.
Figure 1.11: The Page Setup Dialog Box (Windows Systems Only)

### Controls

**Color**
- allows you to specify a color or non-color picture.
  - **Color** selects a color picture.
  - **Gray Scale** selects a grayscale picture.
  - **Monochrome** selects a black-and-white picture.

**Color Quality**
- allows you to specify the color mode used for the picture.
  - **True Color** creates a picture defined by RGB values. This assumes that your printer or display has at least 65536 colors, or “unlimited colors”.
  - **Mapped Color** creates a picture that uses a colormap. This is the right choice for devices that have 256 colors.

**Clipboard Formats**
- allows you to choose the desired format copied to the clipboard. The size of your graphics window can affect the size of the clipboard picture. For best results, experiment with the graphics window size and examine the resulting clipboard picture using the Windows clipboard viewer.
  - **Bitmap** is a bitmap copy of the graphics window.
DIB Bitmap
   is a device-independent bitmap copy of the graphics window.

Metafile
   is a Windows Metafile.

Enhanced Metafile
   is a Windows Enhanced Metafile.

Picture Format
   allows you to specify a raster or a vector picture.

Vector
   creates a vector picture. This format will have a higher resolution when printed, but some large 3D pictures may take a long time to print.

Raster
   creates a raster picture. This format will have a lower resolution when printed, but some large 3D pictures may take much less time to print.

Printer Scale %
   controls the amount of the page that the printed picture will cover. Decreasing the scaling will effectively increase the margin between the picture and the edge of the paper.

Options
   contains options that control other attributes of the picture.

Landscape Orientation (Printer)
   specifies the orientation of the picture. If selected, the picture is made in landscape mode; otherwise, it is made in portrait mode. This option is applicable only when printing.

Reverse Foreground/Background
   specifies that the foreground and background colors of the picture will be swapped. This feature allows you to make a copy of the picture with a white background and a black foreground, while the graphics window is displayed with a black background and white foreground.

1.2. Customizing the Graphical User Interface (Linux Systems Only)

On Linux systems, you may want to customize the graphical user interface by changing attributes such as text color, background color, and text fonts. The program will try to provide default text fonts that are satisfactory for your platform's display size, but in some cases customization may be necessary if the default text fonts make the GUI too small or too large on your display, or if the default colors are undesirable.

The GUI in ANSYS Fluent is based on the X Window System Toolkit and OSF/Motif. The attributes of the GUI are represented by X Window “resources”. If you are unfamiliar with the X Window System Resource Database, refer to any documentation you may have that describes how to use the X Window System or OSF/Motif applications.

The default X Window resource values for a medium resolution display are shown below:

```plaintext
! General resources
!Fluent*geometry: +0-0
Fluent*fontList: "-helvetica-bold-r-normal--12-*."
Fluent*MenuBar*fontList: "-helvetica-bold-r-normal--12-*."
```
To customize one or more of the resources for a particular user, place appropriate resource specification lines in that user's file $HOME/.Xdefaults or whatever resource file is loaded by the X Window System on the user's platform.

To customize one or more of the resources for several users at a site, place the resource specification lines in an application defaults resource file called Fluent. This file should then be installed in a directory such as /usr/lib/X11/app-defaults, or on SUN workstations, the directory may be /usr/openwin/lib/app-defaults. See documentation regarding your platform for more information.

1.3. Using the GUI Help System

ANSYS Fluent includes an integrated help system that provides easy access to the program documentation. Through the graphical user interface, you have the entire User's Guide and other documentation available to you with the click of a mouse button. The User's Guide and other manuals are displayed in the help viewer, which allows you to use hypertext links and the browser's search and index tools to find the information you need.

There are many ways to access the information contained in the online help. You can get reference information from within a task page or dialog box, or (on Linux machines) request context-sensitive help for a particular menu item or dialog box. You can also go to the User's Guide contents page or the viewer index, and use the hypertext links to find the information you are looking for. In addition to the
**User’s Guide**, you can also access the other ANSYS Fluent documentation (for example, the Tutorial Guide or UDF Manual).

Note that the last two chapters of the *User’s Guide* (Task Page Reference Guide (p. 1887) and Menu Reference Guide (p. 2375)) are also referred to as the Reference Guide, and contain a description of each task page, menu item, and dialog box.

The sections that follow provide information on how to get help for a task page or dialog box, and brief descriptions of the Help menu items in ANSYS Fluent. For more information, refer to the information available from the Help menu in the viewer itself. See also, Using Help.

1.3.1. Task Page and Dialog Box Help
1.3.2. Context-Sensitive Help (Linux Only)
1.3.3. Opening the User’s Guide Table of Contents
1.3.4. Opening the Reference Guide
1.3.5. Help on Help
1.3.6. Accessing Printable (PDF) Manuals
1.3.7. Help for Text Interface Commands
1.3.8. Accessing the Customer Portal Web Site
1.3.9. Obtaining License Use Information
1.3.10. Version and Release Information

### 1.3.1. Task Page and Dialog Box Help

To get help about a task page or dialog box that you are currently using, click the Help button in the task page or dialog box. The help viewer will open to the section of the User’s Guide that explains the function of each item in the task page or dialog box. In this section, you will also find hypertext links to more specific section(s) of the User’s Guide that discuss how to use the task page or dialog box and provide related information.

### 1.3.2. Context-Sensitive Help (Linux Only)

If you want to find out how or when a particular menu item or dialog box is used, you can use the context-sensitive help feature. Select the Context-Sensitive Help item in the Help pull-down menu.

**Help → Context-Sensitive Help**

With the resulting question-mark cursor, select an item from a pull-down menu. The help viewer will open to the section of the User’s Guide that discusses the selected item.

### 1.3.3. Opening the User’s Guide Table of Contents

When in solution mode, you can view the User’s Guide table of contents by selecting the User’s Guide Contents... menu item in the Help drop-down menu. Note that this menu item will open the Fluent Meshing User’s Guide table of contents when you are in meshing mode.

**Help → User’s Guide Contents...**

Selecting this item will open the help viewer to the contents page of the User’s Guide (Figure 1.12: The ANSYS Fluent User’s Guide Contents Page (p. 26)). Each item in the table of contents is a hypertext link that you can click to view that chapter or section.
In addition, the Fluent documents are listed in the Table of Contents of the help viewer. These listings can be expanded by clicking the icon to the left of the document title ( ). The expanded list will contain hyperlinks to particular chapters or sections, and may also be expandable. For more information on navigation within the help viewer, refer to the information available from the Help menu in the viewer itself.

1.3.4. Opening the Reference Guide

To open the help system to the first page of the Reference Guide, which contains information about each dialog box or menu item, arranged by pull-down menu, do the following in the help viewer:

1. Expand the Fluent User's Guide in the left pane of the viewer by clicking the icon to the left of the document title.
2. Scroll down to the **Task Page Reference Guide** or **Menu Reference Guide** item in the left pane of the viewer and click the one of interest.

3. Use the hyperlinks in the main viewer window to find the topic of interest, or, expand the item in the left pane of the viewer and scroll to the topic of interest.

### 1.3.5. Help on Help

**Help ➔ Using Help...**

When you select this item, the help viewer will open to the beginning of this section.

You can obtain information about using online help by selecting the **Using Help...** menu item in the **Help** pull-down menu in the help viewer itself. See also, **Using Help**.

### 1.3.6. Accessing Printable (PDF) Manuals

You can download the PDF documentation from the ANSYS Customer Portal ([support.ansys.com/downloads](http://support.ansys.com/downloads)).

If you do not have Acrobat Reader, you can download it for free from Adobe ([www.adobe.com](http://www.adobe.com)).

See the **Getting Started Guide** for more information.

### 1.3.7. Help for Text Interface Commands

There are two ways to find information about text interface commands. You can either go to the **Text Command List** (which can be accessed in the **Contents** tab of the help viewer, as described in **Opening the User’s Guide Table of Contents (p. 25)**), or use the text interface help system described in **Using the Text Interface Help System (p. 38)**.

### 1.3.8. Accessing the Customer Portal Web Site

You can access the ANSYS Customer Portal web site by selecting the **Online Technical Resources...** menu item in the **Help** pull-down menu. You can also access the ANSYS Customer Portal by clicking the ![button](image) button in ANSYS Help Viewer.

**Help ➔ Online Technical Resources...**

ANSYS Fluent will direct your web browser to the appropriate web address.

You can download all ANSYS product documentation, including ANSYS Fluent documentation, from the ANSYS Customer Portal web site. The documentation is available from the ANSYS Customer Portal in PDF format and is appropriate for viewing and printing with Adobe Acrobat Reader.

### 1.3.9. Obtaining License Use Information

If you are running with an existing ANSYS Fluent license (FluentLM) you can obtain a listing of current ANSYS Fluent users when you select the **License Usage...** menu item in the **Help** pull-down menu.

**Help ➔ License Usage...**

ANSYS Fluent will display a list of the current users of the ANSYS Fluent license feature in the console.
If your installation of ANSYS Fluent is managed by the ANSYS License Manager (ANSLIC_ADMIN), you will see a message that will indicate that licensing is managed by ANSLIC_ADMIN. For additional information on licensing information, refer to the Installation and Licensing Documentation within the help viewer. This information can be found by doing the following in the help viewer:

1. Scroll down to the Installation and Licensing Documentation item in the left pane of the viewer.
2. Expand this document by clicking the icon to the left of the document title.
3. Use the hyperlinks in the main viewer window to find the desired information, or, expand the items in the left pane of the viewer and scroll to the topic of interest.

1.3.10. Version and Release Information

You can obtain information about the version and release of ANSYS Fluent you are running by selecting the Version... menu item in the Help pull-down menu.

Help → Version...
In addition to the graphical user interface described in Graphical User Interface (GUI) (p. 1), the user interface in ANSYS Fluent includes a textual command line interface.

2.1. Text Menu System
2.2. Text Prompt System
2.3. Interrupts
2.4. System Commands
2.5. Text Menu Input from Character Strings
2.6. Using the Text Interface Help System

The text interface (TUI) uses, and is written in, a dialect of Lisp called Scheme. Users familiar with Scheme will be able to use the interpretive capabilities of the interface to create customized commands.

2.1. Text Menu System

The text menu system provides a hierarchical interface to the program's underlying procedural interface. Because it is text based, you can easily manipulate its operation with standard text-based tools: input can be saved in files, modified with text editors, and read back in to be executed. Because the text menu system is tightly integrated with the Scheme extension language, it can easily be programmed to provide sophisticated control and customized functionality.

The menu system structure is similar to the directory tree structure of Linux operating systems. When you first start ANSYS Fluent, you are in the “root” menu and the menu prompt is a greater-than symbol.

> 

To generate a listing of the submenus and commands in the current menu, simply press Enter. Note that the available submenus and commands will depend on whether you are in meshing mode or solution mode. The submenus and commands that are available from the root menu of the solution mode are as follows:

`>Enter
adapt/ mesh/ surface/
define/ parallel/ switch-to-meshing-mode
display/ plot/ views/
exit report/
file/ solve/`

Note that `switch-to-meshing-mode` is only available for 3D sessions, before you have read a mesh or a case file.

By convention, submenu names end with a / to differentiate them from menu commands. To execute a command, just type its name (or an abbreviation). Similarly, to move down into a submenu, enter its name or an abbreviation. When you move into the submenu, the prompt will change to reflect the current menu name.

`>display
/display> set
/display/set>`
To move back to the previously occupied menu, type `q` or `quit` at the prompt.

```
/display/set> q
/display>
```

You can move directly to a menu by giving its full pathname.

```
/display> /file
/display//file>
```

In the above example, control was passed from `/display` to `/file` without stopping in the root menu. Therefore, when you quit from the `/file` menu, control will be passed directly back to `/display`.

```
/display//file> q
/display>
```

Furthermore, if you execute a command without stopping in any of the menus along the way, control will again be returned to the menu from which you invoked the command.

```
/display> /file start-journal jrnl
Opening input journal to file "jrnl".
/display>
```

The text menu system provides on-line help for menu commands. The text menu on-line help system is described in Using the Text Interface Help System (p. 38).

To edit the current command, you can position the cursor with the left and right arrow keys, delete with the Backspace key, and insert text simply by typing.

For additional information, see the following sections:

- 2.1.1. Command Abbreviation
- 2.1.2. Command Line History
- 2.1.3. Scheme Evaluation
- 2.1.4. Aliases

### 2.1.1. Command Abbreviation

To select a menu command, you do not need to type the entire name; you can type an abbreviation that matches the command. The rules for matching a command are as follows: A command name consists of phrases separated by hyphens. A command is matched by matching an initial sequence of its phrases. Matching of hyphens is optional. A phrase is matched by matching an initial sequence of its characters. A character is matched by typing that character.

If an abbreviation matches more than one command, then the command with the greatest number of matched phrases is chosen. If more than one command has the same number of matched phrases, then the first command to appear in the menu is chosen.

For example, each of the following will match the command `set-ambient-color`: `set-ambient-color`, `s-a-c`, `sac`, and `sa`. When abbreviating commands, sometimes your abbreviation will match more than one command. In such cases, the first command is selected. Occasionally, there is an anomaly such as `lint` not matching `lighting-interpolation` because the `li` gets absorbed in `lights-on?` and then the `nt` does not match `interpolation`. This can be resolved by choosing a different abbreviation, such as `liin`, or `l-int`. 
### 2.1.2. Command Line History

You can use the up and down arrow keys on your keyboard to go through recently used commands that are stored in history. By default, command-history will store only the last ten commands. This can be changed (for example to 15) by using the following command:

```
> (set! *cmd-history-length* 15)
```

#### Important

Command-history is not available if the ANSYS Fluent application is started with -g options (see Command Line Startup Options in the Getting Started Guide).

#### Important

The user inputs supplied as the arguments of the TUI command or alias will not be saved in history. By way of illustration, consider the following entry in the TUI:

```
> rc new_file.cas
```

#### Important

In history, only `rc` (an alias for `read-case`) will be saved, since `new_file.cas` is a user input to the alias-function.

Commands recalled from history can be edited or corrected using the Backspace key and the left and right arrow keys.

### 2.1.3. Scheme Evaluation

If you enter an open parenthesis, `(`, at the menu prompt, then that parenthesis and all characters up to and including the matching closing parenthesis are passed to Scheme to be evaluated, and the result of evaluating the expression is displayed.

```
> (define a 1)
a
> (+ a 2 3 4)
10
```

### 2.1.4. Aliases

Command aliases can be defined within the menu system. As with the Linux `csh` shell, aliases take precedence over command execution. The following aliases are predefined in Cortex: `error`, `pwd`, `chdir`, `ls`, `..`, and `alias`.

- **error**
  - displays the Scheme object that was the “irritant” in the most recent Scheme error interrupt.

- **pwd**
  - prints the working directory in which all file operations will take place.
2.2. Text Prompt System

Commands require various arguments, including numbers, filenames, yes/no responses, character strings, and lists. A uniform interface to this input is provided by the text prompt system. A prompt consists of a prompt string, followed by an optional units string enclosed in parentheses, followed by a default value enclosed in square brackets. The following shows some examples of prompts:

```
filled-mesh? [no] Enter
shrink-factor [0.1] Enter
line-weight [1] Enter
title ["""] Enter
```

The default value for a prompt is accepted by pressing Enter on the keyboard or typing a , (comma).

**Important**

Note that a comma is not a separator. It is a separate token that indicates a default value. The sequence "1,2" results in three values; the number 1 for the first prompt, the default value for the second prompt, and the number 2 for the third prompt.

A short help message can be displayed at any prompt by entering a ?. (See Using the Text Interface Help System (p. 38).)

To abort a prompt sequence, simply press Ctrl+c.

For additional information, see the following sections:
- 2.2.1. Numbers
- 2.2.2. Booleans
- 2.2.3. Strings
- 2.2.4. Symbols
- 2.2.5. Filenames
- 2.2.6. Lists
- 2.2.7. Evaluation
- 2.2.8. Default Value Binding

2.2.1. Numbers

The most common prompt type is a number. Numbers can be either integers or reals. Valid numbers are, for example, 16, -2.4, .9E5, and +1E-5. Integers can also be specified in binary, octal, and hexadecimal form. The decimal integer 31 can be entered as 31, #b11111, #o37, or #x1f. In Scheme,
integers are a subset of reals, so you do not need a decimal point to indicate that a number is real; 2 is just as much a real as 2.0. If you enter a real number at an integer prompt, any fractional part will simply be truncated; 1.9 will become 1.

2.2.2. Booleans

Some prompts require a yes-or-no response. A yes/no prompt will accept either yes or y for a positive response, and no or n for a negative response. Yes/no prompts are used for confirming potentially dangerous actions such as overwriting an existing file, exiting without saving case, data, mesh, etc.

Some prompts require actual Scheme boolean values (true or false). These are entered with the Scheme symbols for true and false, #t and #f.

2.2.3. Strings

Character strings are entered in double quotes, for example, “red”. Plot titles and plot legend titles are examples of character strings. Character strings can include any characters, including blank spaces and punctuation.

2.2.4. Symbols

Symbols are entered without quotes. Zone names, surface names, and material names are examples of symbols. Symbols must start with an alphabetical character (that is, a letter), and cannot include any blank spaces or commas.

2.2.5. Filenames

Filenames are actually just character strings. For convenience, filename prompts do not require the string to be surrounded with double quotes. If, for some exceptional reason, a filename contains an embedded space character, then the name must be surrounded with double quotes.

One consequence of this convenience is that filename prompts do not evaluate the response. For example, the sequence

> (define fn "valve.ps")

fn

> hc fn

will end up writing a picture file with the name fn, not valve.ps. Since the filename prompt did not evaluate the response, fn did not get a chance to evaluate “valve.ps” as it would for most other prompts.

2.2.6. Lists

Some functions in ANSYS Fluent require a “list” of objects such as numbers, strings, booleans, etc. A list is a Scheme object that is simply a sequence of objects terminated by the empty list, ’(). Lists are prompted for an element at a time, and the end of the list is signaled by entering an empty list. This terminating list forms the tail of the prompted list, and can either be empty or can contain values. For convenience, the empty list can be entered as () as well as the standard form ’(). Normally, list prompts save the previous argument list as the default. To modify the list, overwrite the desired elements and terminate the process with an empty list. For example,
element (1) [()] 1
element (2) [()] 10
element (3) [()] 100
element (4) [()] Enter

creates a list of three numbers: 1, 10, and 100. Subsequently,

element (1) [1] Enter
element (2) [10] Enter
element (3) [100] Enter
element (4) [()] 1000

element (5) [()] Enter

adds a fourth element. Then

element (1) [1] Enter
element (2) [10] Enter

element (3) [100] ()

leaves only 1 and 10 in the list. Subsequently entering

element (1) [1],,'(11 12 13)

creates a five element list: 1, 10, 11, 12, and 13. Finally, a single empty list removes all elements

element (1) [1] ()

A different type of list, namely, a “list-of-scalars” contains pick menu items (and not list items) for which a selection has to be made from listed quantities, which are available at the Enter prompt. Hence, a list-of-scalars cannot be entered as a list.

An example of a “list-of-scalars” consists of the following:
2.2.7. Evaluation

All responses to prompts (except filenames, see above) are evaluated by the Scheme interpreter before they are used. You can therefore enter any valid Scheme expression as the response to a prompt. For example, to enter a unit vector with one component equal to 1/3 (without using your calculator),

```scheme
(set-xy
  (x-component [1.0] (/ 1 3))
  (y-component [0.0] (sqrt (/ 8 9)))
)
```

or, you could first define a utility function to compute the second component of a unit vector,

```scheme
(define (unit-y x) (sqrt (- 1.0 (* x x)))
```

and then use it to compute the second component of a unit vector.

```scheme
(set-xy
  (x-component [1.0] (/ 1 3))
  (unit-y x)
)
```
2.2.8. Default Value Binding

The default value at any prompt is bound to the Scheme symbol "_" (underscore) so that the default value can form part of a Scheme expression. For example, if you want to decrease a default value so that it is one-third of the original value, you could enter

\[ \text{shrink-factor} [0.8] \ (/_ \ 3) \]

2.3. Interrupts

The execution of the code can be halted by pressing the Control+c, at which time the present operation stops at the next recoverable location.

2.4. System Commands

The way you execute system commands with the ! (bang) shell escape character will be slightly different for Linux and Windows systems.

For additional information, see the following sections:

2.4.1. System Commands for Linux-based Operating Systems
2.4.2. System Commands for Windows Operating Systems

2.4.1. System Commands for Linux-based Operating Systems

If you are running ANSYS Fluent under a Linux-based operating system, all characters following the ! up to the next newline character will be executed in a subshell. Any further input related to these system commands must be entered in the window in which you started the program, and any screen output will also appear in that window. (Note that if you started ANSYS Fluent remotely, this input and output will be in the window in which you started Cortex.)

\[ > \text{!rm junk.*} \]
\[ > \text{!vi script.rp} \]

!pwd and !ls will execute the Linux commands in the directory in which Cortex was started. The screen output will appear in the window in which you started ANSYS Fluent, unless you started it remotely, in which case the output will appear in the window in which you started Cortex. (Note that !cd executes in a subshell, so it will not change the working directory either for ANSYS Fluent or for Cortex, and is therefore not useful.) Typing cd with no arguments will move you to your home directory in the console.

ANSYS Fluent includes three system command aliases (pwd, ls, and chdir) that will be executed in your working directory with output displayed in the ANSYS Fluent console. Note that these aliases will invoke the corresponding Linux commands with respect to the parent directory of the case file. For example, pwd prints the parent directory of the case file in the ANSYS Fluent console, while !pwd prints the directory from which you started ANSYS Fluent in the Linux shell window where you started ANSYS Fluent.

Several examples of system commands entered in the console are shown below. The screen output that will appear in the window in which ANSYS Fluent was started (or, if you started the program remotely, in the window in which Cortex was started) follows the examples.
Example input (in the ANSYS Fluent console):

> !pwd
> !ls valve*.*

Example output (in the window in which ANSYS Fluent—or Cortex, if you started the program remotely—was started):

/home/cfd/run/valve
   valve1.cas  valve1.msh  valve2.cas  valve2.msh

2.4.2. System Commands for Windows Operating Systems

If you are running ANSYS Fluent under a Windows operating system, all characters following the ! up to the next newline character will be executed. The results of a command will appear in the ANSYS Fluent console, or in a separate window if the command starts an external program, such as Notepad.

> !del junk.*
> !notepad script.rp

!cd and !dir will execute the DOS commands and the screen output will appear in the ANSYS Fluent console. The !cd command with no argument will display the current working directory in the ANSYS Fluent console.

Several examples of system commands entered in the console are shown below.

Example input (in boxes) and output (in the ANSYS Fluent console):

> !cd
p:/cfd/run/valve
> !dir valve*.*/w

Volume in drive P is users
Volume Serial Number is 1234-5678
Directory of p:/cfd/run/valve
valve1.cas  valve1.msh  valve2.cas  valve2.msh
4 File(s)              621,183 bytes
0 Dir(s)          1,830,088,704 bytes free

2.5. Text Menu Input from Character Strings

Often, when writing a Scheme extension function for ANSYS Fluent, it is convenient to be able to include menu commands in the function. This can be done with ti-menu-load-string. For example, to open graphics window 2, use

(ti-menu-load-string "di ow 2")

A Scheme loop that will open windows 1 and 2 and display the front view of the mesh in window 1 and the back view in window 2 is given by

(for-each
 (lambda (window view)
    (ti-menu-load-string (format #f "di ow ~a gr view rv ~a" window view)))
 '(1 2)
 '(front back))

This loop makes use of the format function to construct the string used by menu-load-string. This simple loop could also be written without using menu commands at all, but you need to know the Scheme functions that get executed by the menu commands to do it:
String input can also provide an easy way to create aliases within ANSYS Fluent. For example, to create an alias that will display the mesh, you could type the following:

```
(alias 'dg (lambda () (ti-menu-load-string "/di gr")))
```

Then any time you enter `dg` from anywhere in the menu hierarchy, the mesh will be drawn in the active window.

**Important**

`ti-menu-load-string` evaluates the string argument in the top level menu. It ignores any menu you may be in when you invoke `ti-menu-load-string`.

As a result, the command

```
(ti-menu-load-string "open-window 2 gr") ; incorrect usage
```

will not work even if you type it from within the `display/` menu—the string itself must cause control to enter the `display/` menu, as in

```
(ti-menu-load-string "display open-window 2 mesh")
```

### 2.6. Using the Text Interface Help System

The text user interface provides context-sensitive on-line help. Within the text menu system, you can obtain a brief description of each of the commands by entering a `?` followed by the command in question.

**Example:**

```
> ?dis
```

`display/: Enter the display menu.`

You can also enter a lone `?` to enter “help mode.” In this mode, you need only enter the command or menu name to display the help message. To exit the help mode type `q` or `quit` as for a normal menu.

**Example:**

```
> ?
```

`[help-mode]> di`

`display/: Enter the display menu.`

`[help-mode]> pwd`

`pwd: #[alias]
(LAMBDA ()
(BEGIN
(SET! pwd-cmd ((LAMBDA n
n) 'system (IF (cx-send '(unix?)
"pwd"
"cd")))
(cx-send pwd-cmd)))`
To access the help, type `?` at the prompt when you are prompted for information.

Example:

```plaintext
> display/annotate Annotation text "" ?
Annotation text ""
```
Chapter 3: Reading and Writing Files

During an ANSYS Fluent session you may need to import and export several kinds of files. Files that are read include mesh, case, data, profile, Scheme, and journal files. Files that are written include case, data, profile, journal, and transcript files. ANSYS Fluent also has features that enable you to save pictures of graphics windows. You can also export data for use with various visualization and postprocessing tools. These operations are described in the following sections.

3.1. Shortcuts for Reading and Writing Files
3.2. Reading Mesh Files
3.3. Reading and Writing Case and Data Files
3.4. Reading and Writing Parallel Data Files
3.5. Reading Fluent/UNS and RAMPANT Case and Data Files
3.6. Reading and Writing Profile Files
3.7. Reading and Writing Boundary Conditions
3.8. Writing a Boundary Mesh
3.9. Reading Scheme Source Files
3.10. Creating and Reading Journal Files
3.11. Creating Transcript Files
3.12. Importing Files
3.13. Exporting Solution Data
3.14. Exporting Solution Data after a Calculation
3.15. Exporting Steady-State Particle History Data
3.16. Exporting Data During a Transient Calculation
3.17. Exporting to ANSYS CFD-Post
3.18. Managing Solution Files
3.19. Mesh-to-Mesh Solution Interpolation
3.20. Mapping Data for Fluid-Structure Interaction (FSI) Applications
3.21. Saving Picture Files
3.22. Setting Data File Quantities
3.23. The .fluent File

3.1. Shortcuts for Reading and Writing Files

The following features in ANSYS Fluent make reading and writing files convenient:

• Automatic appending or detection of default file name suffixes

• Binary file reading and writing

• Automatic detection of file format (text/binary)

• Recent file list

• Reading and writing of compressed files

• Tilde expansion

• Automatic numbering of files
• Ability to disable the overwrite confirmation prompt

• Standard toolbar buttons for reading and writing files

For additional information, see the following sections:
3.1.1. Default File Suffixes
3.1.2. Binary Files
3.1.3. Detecting File Format
3.1.4. Recent File List
3.1.5. Reading and Writing Compressed Files
3.1.6. Tilde Expansion (Linux Systems Only)
3.1.7. Automatic Numbering of Files
3.1.8. Disabling the Overwrite Confirmation Prompt
3.1.9. Toolbar Buttons

3.1.1. Default File Suffixes

Each type of file read or written in ANSYS Fluent has a default file suffix associated with it. When you specify the first part of the file name (the prefix) for the commonly used files, Fluent automatically appends or detects the appropriate suffix. For example, to write a case file named myfile.cas, just specify the prefix myfile in the Select File dialog box (Figure 3.1: The Select File Dialog Box (p. 42)) and .cas is automatically appended. Similarly, to read the case file named myfile.cas into Fluent, you can just specify myfile and ANSYS Fluent automatically searches for a file of that name with the suffix .cas.

Figure 3.1: The Select File Dialog Box

![Select File Dialog Box](image)
The default file suffix for case and data files, PDF (Probability Density Function) files, DTRM ray files, profiles, scheme files, journal files, etc., are automatically detected and appended. The appropriate default file suffix appears in the Select File dialog box for each type of file.

### 3.1.2. Binary Files

When you write a case, data, or ray file, a binary file is saved by default. Binary files take up less memory than text files and can be read and written by ANSYS Fluent more quickly.

**Note**

You cannot read and edit a binary file, as you can do for a text file.

To save a text file, turn off the Write Binary Files option in the Select File dialog box when you are writing the file.

### 3.1.3. Detecting File Format

When you read a case, data, mesh, PDF, or ray file, Fluent automatically determines whether it is a text (formatted) or binary file.

### 3.1.4. Recent File List

At the bottom of the File/Read submenu there is a list of four ANSYS Fluent case files that you most recently read or wrote. To read one of these files into ANSYS Fluent, select it in the list. This allows you to read a recently used file without selecting it in the Select File dialog box.

Note that the files listed in this submenu may not be appropriate for your current session (for example, a 3D case file can be listed even if you are running a 2D version of ANSYS Fluent). Also, if you read a case file using this shortcut, the corresponding data file is read only if it has the same base name as the case file (for example, file1.cas and file1.dat) and it was read/written with the case file the last time the case file was read/written.

### 3.1.5. Reading and Writing Compressed Files

For more information, see the following sections:

- **3.1.5.1. Reading Compressed Files**
- **3.1.5.2. Writing Compressed Files**

#### 3.1.5.1. Reading Compressed Files

You can use the Select File dialog box to read files compressed using compress or gzip. If you select a compressed file with a .Z extension, ANSYS Fluent automatically invokes zcat to import the file. If you select a compressed file with a .gz extension, Fluent invokes gunzip to import the file.

For example, if you select a file named flow.msh.gz, Fluent reports the following message indicating that the result of the gunzip is imported into ANSYS Fluent via an operating system pipe.

```
Reading "\"| gunzip -c "Y:\flow.msh.gz"\""
```

You can also type in the file name without any suffix (for example, if you are not sure whether or not the file is compressed). First, Fluent attempts to open a file with the input name. If it cannot find a file with that name, it attempts to locate files with default suffixes and extensions appended to the name.
For example, if you enter the name file-name, Fluent traverses the following list until it finds an existing file:

- file-name
- file-name.gz
- file-name.Z
- file-name.suffix
- file-name.suffix.gz
- file-name.suffix.Z

where suffix is a common extension to the file, such as .cas or .msh. Fluent reports an error if it fails to find an existing file with one of these names.

**Note**

In addition to .gz and .Z compression, ANSYS Fluent can also handle .bz2 compressed files.

**Important**

- For Windows systems, only files that were compressed with gzip (that is, files with a .gz extension) can be read. Files that were compressed with compress cannot be read into ANSYS Fluent on a Windows machine.

- Do not read a compressed ray file; ANSYS Fluent cannot access the ray tracing information properly from a compressed ray file.

### 3.1.5.2. Writing Compressed Files

You can use the Select File dialog box to write a compressed file by appending a .Z or .gz extension onto the file name.

For example, if you enter flow.gz as the name for a case file, Fluent reports the following message:

```
Writing "gzip -cfv > Y:\flow.cas.gz"
```
The status message indicates that the case file information is being piped into the \texttt{gzip} command, and that the output of the compression command is being redirected to the file with the specified name. In this particular example, the \texttt{.cas} extension is added automatically.

\begin{itemize}
  \item \textbf{Note} \textbf{In addition to .gz and .Z compression, ANSYS Fluent can also handle .bz2 compressed files.}
\end{itemize}

\begin{itemize}
  \item \textbf{Important} \textbf{In addition to .gz and .Z compression, ANSYS Fluent can also handle .bz2 compressed files.}
  \begin{itemize}
    \item For Windows systems, compression can be performed only with \texttt{gzip}. That is, you can write a compressed file by appending \texttt{.gz} to the name, but appending \texttt{.Z} does not compress the file.
    \item Do not write a compressed ray file; ANSYS Fluent cannot access the ray tracing information properly from a compressed ray file.
    \item To compress parallel data files (that is, files saved with a \texttt{.pdat} extension), you must use asynchronous file compression. (For details, see \texttt{Reading and Writing Case and Data Files (p. 47)}.)
  \end{itemize}
\end{itemize}

\subsection*{3.1.6. Tilde Expansion (Linux Systems Only)}

On Linux systems, if you specify \texttt{~} as the first two characters of a file name, the \texttt{~} is expanded as your home directory. Similarly, you can start a file name with \texttt{~username/}, and the \texttt{~username} is expanded to the home directory of "username". If you specify \texttt{~} as the case file to be written, ANSYS Fluent saves the file \texttt{file.cas} in your home directory. You can specify a subdirectory of your home directory as well: if you enter \texttt{~/cases/file.cas}, ANSYS Fluent saves the file \texttt{file.cas} in the \texttt{cases} subdirectory.

\subsection*{3.1.7. Automatic Numbering of Files}

There are several special characters that you can include in a file name. Using one of these character strings in your file name provides a shortcut for numbering the files based on various parameters (that is, iteration number, time step, or total number of files saved so far), because you need not enter a new file name each time you save a file. (See also \texttt{Automatic Saving of Case and Data Files (p. 49)} for information about saving and numbering case and data files automatically.)

\begin{itemize}
  \item For transient calculations, you can save files with names that reflect the time step at which they are saved by including the character string \texttt{%t} in the file name. For example, you can specify \texttt{contours-%t.ps} for the file name, and Fluent saves a file with the appropriate name (for example, \texttt{contours-001.ps} if the solution is at the first time step).
  \item This automatic saving of files with the time step should not be used for steady-state cases, since the time step will always remain zero.
  \item For transient calculations, you can save files with names that reflect the flow-time at which they are saved by including the character string \texttt{%f} in the file name. The usage is similar to \texttt{%t}. For example, when you specify \texttt{filename-%f.ps} for the file name, Fluent will save a file with the appropriate name (for example, \texttt{filename-005.000000.ps} for a solution at a flow-time of 5 seconds). By default, the flow-time that is included in the file name will have a field width of 10 and 6 decimal places. To modify this format, use
\end{itemize}
the character string \%x . y f, where \( x \) and \( y \) are the preferred field width and number of decimal places, respectively. ANSYS Fluent will automatically add zeros to the beginning of the flow-time to achieve the prescribed field width. To eliminate these zeros and left align the flow-time, use the character string \%–x . y f instead.

This automatic saving of files with flow-time should not be used for steady-state cases, since the flow-time will always remain zero.

- To save a file with a name that reflects the iteration at which it is saved, use the character string \%i in the file name. For example, you can specify contours-%i.ps for the file name, and Fluent saves a file with the appropriate name (for example, contours-0010.ps if the solution is at the 10th iteration).

- To save a picture file with a name that reflects the total number of picture files saved so far in the current Fluent session, use the character string \%n in the file name. This option can be used only for picture files.

The default field width for \%i, \%t, and \%n formats is 4. You can change the field width by using \%xi, \%xt, and \%xn in the file name, where \( x \) is the preferred field width.

### 3.1.8. Disabling the Overwrite Confirmation Prompt

By default, if you ask ANSYS Fluent to write a file with the same name as an existing file in that folder, it will ask you to confirm that it is “OK to overwrite” the existing file. If you do not want Fluent to ask you for confirmation before it overwrites existing files, you can use the **Batch Options** dialog box (see **Batch Execution Options** in the Getting Started Guide for details). Alternatively, enter the `file/confirm-overwrite?` text command and answer no (see **Text User Interface (TUI)** (p. 29) for the text user interface commands).

### 3.1.9. Toolbar Buttons

The standard toolbar provides buttons that make it easier to read and write files:

- The **Read a file** button ( ) allows you to read existing files using a file selection dialog box. The files available for reading include all those available through the **File/Read** menu item, as described in this chapter.

- The **Write a file** button ( ) allows you to write various types of files. The files available for writing include all those available through the **File/Write** menu item, as described in this chapter.

### 3.2. Reading Mesh Files

Mesh files are created using the mesh generators (ANSYS Meshing, the meshing mode of Fluent, TGrid, GAMBIT, GeoMesh, and PreBFC), or by several third-party CAD packages. From the point of view of ANSYS Fluent, a mesh file is a subset of a case file (described in **Reading and Writing Case Files** (p. 48)). The mesh file contains the coordinates of all the nodes, connectivity information that tells how the nodes are connected to one another to form faces and cells, and the zone types and numbers of all the faces (for example, wall-1, pressure-inlet-5, symmetry-2).

The mesh file does not contain any information on boundary conditions, flow parameters. For information about meshes, see **Reading and Manipulating Meshes** (p. 113).
To read a native-format mesh file (that is, a mesh file that is saved in the ANSYS Fluent format, which includes FLUENT 5/6, Fluent/UNS, or RAMPANT meshes) into Fluent, use the **File/Read/Mesh**... menu item.

**File → Read → Mesh...**

Note that you can also use the **File/Read/Case...** menu item (described in Reading and Writing Case Files (p. 48)), because a mesh file is a subset of a case file. ANSYS Meshing, the meshing mode of Fluent, TGrid, GAMBIT, GeoMesh, and PreBFC can all write a native-format mesh file. For information about these files and how they are created, see ANSYS Meshing Mesh Files (p. 134), Fluent Meshing Mode Mesh Files (p. 134), TGrid Mesh Files (p. 134), GAMBIT Mesh Files (p. 134), GeoMesh Mesh Files (p. 134), and PreBFC Mesh Files (p. 134).

If after reading in a mesh file (or a case and data file), you would like to read in another mesh file, the **Read Mesh Options Dialog Box** (p. 2376) will open, where you can choose to

- Discard the case and read in a new mesh.
- Replace the existing mesh.

You also have the option to have the **Scale Mesh** dialog box appear automatically for you to check or scale your mesh, which in general is the recommended practice. For this to happen, enable **Show Scale Panel** after replacing mesh.

For information on importing an unpartitioned mesh file into the parallel version of Fluent using the partition filter, see Using the Partition Filter (p. 1874).

For information about reading surface mesh files, see Reading Surface Mesh Files (p. 147).

### 3.3. Reading and Writing Case and Data Files

Information related to the ANSYS Fluent simulation is stored in both the case file and the data file. The commands for reading and writing these files are described in the following sections, along with commands for the automatic saving of case and data at specified intervals.

ANSYS Fluent can read and write either text or binary case and data files. Binary files require less storage space and are faster to read and write. By default, ANSYS Fluent writes files in binary format. To write a text file, disable the **Write Binary Files** check button in the **Select File** dialog box. In addition, you can read and write either text or binary files in compressed formats (For details, see Reading and Writing Compressed Files (p. 43)). ANSYS Fluent automatically detects the file type when reading.

Furthermore, when writing case and data files, ANSYS Fluent can improve I/O performance using asynchronous file compression which can be enabled using the **Optimize Using Asynchronous I/O** check button in the **Select File** dialog box.

This option is particularly beneficial if you want to improve the overall performance of simulations involving solution check-pointing. Performance is improved by overlapping the file compression and file system copy operations with subsequent iterations or other operations. It is best if the front end Cortex
process has its own dedicated processor core (or machine) not used by the ANSYS Fluent compute-node processes, even though the option would aid performance even if they reside on the same machine.

**Important**

- The **Optimize Using Asynchronous I/O** option is not available on Windows machines.
- If you adapt the mesh, you must save a new case file as well as a data file. Otherwise, the new data file will not correspond to the case file (for example, they will have different numbers of cells). If you have not saved the latest case or data file, ANSYS Fluent will warn you when you try to exit the program.

For additional information, see the following sections:
  - 3.3.1. Reading and Writing Case Files
  - 3.3.2. Reading and Writing Data Files
  - 3.3.3. Reading and Writing Case and Data Files Together
  - 3.3.4. Automatic Saving of Case and Data Files

### 3.3.1. Reading and Writing Case Files

Case files contain the mesh, boundary and cell zone conditions, and solution parameters for a problem. It also contains the information about the user interface and graphics environment. For information about the format of case files see Case and Data File Formats (p. 2533). The commands used for reading case files can also be used to read native-format mesh files (as described in Reading Mesh Files (p. 46)) because the mesh information is a subset of the case information. Select the **File/Read/Case...** menu item to invoke the **Select File** dialog box.

**File → Read → Case...**

Read a case file using the **Select File** dialog box. Note that the **Display Mesh After Reading** option in the **Select File** dialog box allows you to have the mesh displayed automatically after it is read.

Select the **File/Write/Case...** menu item to invoke the **Select File** dialog box.

**File → Write → Case...**

Write a case file using the **Select File** dialog box.

When ANSYS Fluent reads a case file, it first looks for a file with the exact name you typed. If a file with that name is not found, it searches for the same file with different extensions (Reading and Writing Compressed Files (p. 43)). When ANSYS Fluent writes a case file, `.cas` is added to the name you type unless the name already ends with `.cas`.

### 3.3.2. Reading and Writing Data Files

Data files contain the values of the specified flow field quantities in each mesh element and the convergence history (residuals) for that flow field. For information about the format of data files see Case and Data File Formats (p. 2533).

After reading a mesh or case file, select the **File/Read/Data...** menu item to invoke the **Select File** dialog box.
Reading and Writing Case and Data Files

File → Read → Data...

Read a data file using the Select File dialog box.

After generating data for a case file, select the File/Write/Data... menu item to invoke the Select File dialog box.

File → Write → Data...

Write a data file using the Select File dialog box.

When ANSYS Fluent reads a data file, it first looks for a file with the exact name you typed. If a file with that name is not found, it searches for the same file with different extensions (Reading and Writing Compressed Files (p. 43)). When ANSYS Fluent writes a data file, .dat is added to the name you type unless the name already ends with .dat.

3.3.3. Reading and Writing Case and Data Files Together

A case file and a data file together contain all the information required to restart a solution. Case files contain the mesh, boundary and cell zone conditions, and solution parameters. Data files contain the values of the flow field in each mesh element and the convergence history (residuals) for that flow field.

You can read a case file and a data file together by using the Select File dialog box invoked by selecting the File/Read/Case & Data... menu item. To read both files, select the appropriate case file, and the corresponding data file (same name with .dat suffix) is also read. Note that the Display Mesh After Reading option in the Select File dialog box allows you to have the mesh displayed automatically after it is read.

File → Read → Case & Data...

To write a case file and a data file, select the File/Write/Case & Data... menu item.

File → Write → Case & Data...

3.3.4. Automatic Saving of Case and Data Files

You can request ANSYS Fluent to automatically save case and data files at specified intervals during a calculation. This is especially useful for time-dependent calculations, since it allows you to save the results at different time steps or flow times without stopping the calculation and performing the save manually. You can also use the autosave feature for steady-state problems, and thus examine the solution at different stages in the iteration history.

Automatic saving is specified using the Autosave Dialog Box (p. 2256) (Figure 3.2: The Autosave Dialog Box (p. 50)), which is opened by clicking the Edit... button next to the Autosave Every text box in the Calculation Activities task page.
Specify how often you would like to save your modified files by entering the frequency in the **Save Data File Every** number-entry field. **Save Data File Every** is set to zero by default, indicating that no automatic saving is performed.

If you choose to save the case file only if it is modified, then select **If Modified During the Calculation or Manually** under **When the Data File is Saved, Save the Case File**. Note that the case file will be saved whether you make a manual change, or if ANSYS Fluent makes a change internally during the calculation. If you choose to save the case file every time the data file is saved, then select **Each Time**.

---

**Important**

To save only the data files, use the following TUI option:

```
file → auto-save → case-frequency → if-mesh-is-modified
```

This will result in the options in the **When the Data File is Saved, Save the Case** group box being disabled in the **Autosave** dialog box. In essence, this TUI command forces ANSYS Fluent to the save case file only when the mesh is modified. It does not disable case file saving, but reduces it to an absolute minimum. This is necessary to do so since you cannot read a data file without a case file containing a matching mesh.

For steady-state solutions, specify the frequency in iterations. For transient solutions, specify it in time steps (unless you are using the explicit time stepping formulation, in which case specify the frequency in iterations). If you define a frequency of 5, for example, a case file is saved every 5 iterations or time steps.

If you have limited disk space, restrict the number of files saved by ANSYS Fluent by selecting the **Retain Only the Most Recent Files** option. When selected, enter the **Maximum Number of Data Files** you would like to retain. Note that the case and data files are treated separately with regard to the maximum number of files saved when overwriting. For example, if the value of **Maximum Number of Data Files** is set to five, ANSYS Fluent saves a maximum of five case and five data files, irrespective of the frequency.
After the maximum limit of files has been saved, ANSYS Fluent begins overwriting the earliest existing file.

**Note**

When the **Retain only the Most Recent Files** option is selected, the solution history currently in memory will be discarded and the solution history reset.

If you have generated data (either by initializing the solution or running the calculation) you can view the list of standard quantities that will be written to the data file as a result of the autosave, and even select additional quantities for postprocessing in alternative applications. Click the **Data File Quantities** button to open the **Data File Quantities** dialog box, and make any necessary selections. For details, see [Setting Data File Quantities](p. 106).

Enter a root name for the autosave files in the **File Name** text box. When the files are saved, a number will be appended to this root name to indicate the point at which it was saved during the calculation: for steady-state solutions, this will be the iteration number, whereas for transient solutions it will be either the time step number or flow time (depending on your selection in the step that follows). An extension will also be automatically added to the root name (.cas or .dat). If the specified **File Name** ends in .gz or .Z, appropriate file compression is performed. For details about file compression see [Reading and Writing Compressed Files](p. 43).

For transient calculations, make a selection from the **Append File Name with** drop-down list to indicate whether you want the root file name to be appended with the **time-step** or **flow-time** (see **Figure 3.2: The Autosave Dialog Box** (p. 50)). If you select the latter, you can set the **Decimal Places in File Name** to determine the ultimate width of the file name.

Consider a transient case for which you want to save your case and data files at known time steps. The procedure you would follow is to first set the frequency in the **Save Data File Every** text box. Select **Each Time** if you want both case and data files saved at the same interval. Then enter `my_file` for the **File Name**. Finally, select **time-step** from the **Append File Name with** drop-down list. An example of the resulting files saved would be

```
my_file-0005.cas
my_file-0005.dat
```

indicating that these files were saved at the fifth time step.

You can revise the instructions for the previous example to instead save case and data files at known flow times, by selecting **flow-time** from the **Append File Name with** drop-down list. The default **Decimal Places in File Name** will be six. An example of the resulting files saved would be

```
my_file-0.500000.cas
my_file-0.500000.dat
```

indicating that these files were saved at a flow time of 0.5 seconds.

For steady-state and transient cases, you have the option of automatically numbering the files (as described in [Automatic Numbering of Files](p. 45)), and thereby include further information about when the files were saved. This involves the addition of special characters to the **File Name**. For example, you may want the file names to convey the flow times with their corresponding time steps (transient cases only). Select **time-step** from the **Append File Name with**, and enter a **File Name** that ends with
Entering a **File Name** of `filename-%f` could result in a saved case file named `filename-000.500000-0010.cas`. The conventions used in this example can be explained as follows:

- **filename-** is the file name you entered when autosaving your solution.
- **000.500000** is the result of the special character `%f` added to the file name, and is the flow time. This flow time has a field width of ten characters, which allows for six decimal places (as discussed in *Automatic Numbering of Files* (p. 45)).
- **-0010** is the appended **time-step**, as designated by the selection in the **Append File Name with** dropdown list.
- **.cas** is the file extension automatically added when using the autosave option.

All of the autosave inputs are stored in memory when you click **OK** in the **Autosave** dialog box, and can then be saved with the case file.

### 3.4. Reading and Writing Parallel Data Files

When performing parallel processing, you have the option of utilizing the parallel input/output (I/O) capability of ANSYS Fluent. This capability permits the writing and reading of data files directly to and from the node processes in a parallel fashion. This is in contrast to the standard ANSYS Fluent I/O approach, in which all data is passed from the node processes to the host process where it is then written out to disk in serial. The motivation for performing the I/O directly from the node processes is to reduce the time for the data file I/O operations.

During parallel I/O operations, all the node processes write to or read from the same file, that is, they concurrently access a single file. The format of this parallel data file is different than the format of the standard ANSYS Fluent data file. The format has been revised to permit more efficient concurrent access. The order of data written to the parallel data file is dependent on the number of processes involved in the session and on the partitioning. However, a parallel data file written from any parallel session on a given platform (that is, any number of processes or partitioning) can be read by any other parallel session on the same platform. In other words, analyses may be freely restarted using a different number of processes, as long as the files are being written or read from the same platform.

For additional information, see the following sections:

- 3.4.1. **Writing Parallel Data Files**
- 3.4.2. **Reading Parallel Data Files**
- 3.4.3. **Availability and Limitations**

#### 3.4.1. Writing Parallel Data Files

To write a parallel data file, select the **File/Write/Data...** menu item to invoke the **Select File** dialog box.

**File → Write → Data...**

In the **Select File** dialog box, enter the name of the output data file with a `.pdat` extension. The parallel data files are always binary, so you do not have to enable the **Write Binary Files** option.
Note that parallel data files written from sessions with different numbers of processes may be slightly different in size. However, they contain essentially the same information.

You can also use the text command `file/write-pdat?` to write a `.pdat` file. This is particularly useful if you want to write a `.pdat` file using the autosave data file option, after reading in a data file. The `.pdat` files will be saved during the autosave.

### 3.4.2. Reading Parallel Data Files

To read parallel data files, select the **File/Read/Data...** menu item to invoke the **Select File** dialog box.

**File → Read → Data...**

In the **Select File** dialog box, enter the name of the input data file with a `.pdat` extension.

Note that a parallel file will be read slightly quicker into a session that uses the same number of processes as the session that originally wrote the file, as opposed to a session with a different number.

### 3.4.3. Availability and Limitations

The conditions in which parallel I/O is available and the limitations related to this capability are as follows:

- The parallel I/O capability is only available for parallel ANSYS Fluent sessions. Parallel data files cannot be read into a serial ANSYS Fluent session, although they can be read if ANSYS Fluent is launched with the number of processes set to one (for example, enter 1 for **Number of Processes** in Fluent Launcher).

- On a given platform, compatibility of data files will be a function of MPI type, but not interconnect.
  - Within the same MPI on a given platform, data files will be compatible regardless of the interconnect (that is, writing with Platform MPI/ ethernet and reading with Platform MPI/ infiniband is allowed).
  - Inter-MPI compatibility on the same platform may also exist, since most of the MPIs use the same MPI-O implementation (ROMIO), but this is not guaranteed.

- Parallel data files written on one platform may not necessarily be readable on other platforms. For example, compatibility across 64-bit platforms with the same endianness (byte order) may even exist (for example, `lnamd64`); however, this is not guaranteed by the standard (since the “native” format is used) and should be investigated on a case-by-case basis.

- No parallel I/O capabilities are currently available for case files.

- The parallel/IO capability is designed to work on true parallel file systems designed for concurrent, single-file access. The capability is not supported on NFS, for example.

- File compression with parallel I/O is supported via asynchronous operation. Inline compression as with standard I/O is not possible. (For details, see Reading and Writing Case and Data Files (p. 47)).

- The general parallel I/O capability is only available with certain MPIs on certain platforms. The supported combinations are listed in Table 3.1: Architecture/MPI Combinations Compatible with Parallel I/O (p. 54).
Some of the MPIs currently used on Linux systems do not support MPI-2 features used in the parallel I/O. The default MPIs on all Linux and Windows systems should support the capability.

**Important**

Not all MPIs on a given platform work with all interconnects. For information about compatibility, see Table 34.7: Supported MPIs for Linux Architectures (Per Interconnect) (p. 1851).

### Table 3.1: Architecture/MPI Combinations Compatible with Parallel I/O

<table>

### 3.5. Reading Fluent/UNS and RAMPANT Case and Data Files

Case files created by Fluent/UNS 3 or 4 or RAMPANT 2, 3, or 4 can be read into ANSYS Fluent in the same way that current case files are read (see Reading and Writing Case and Data Files (p. 47)). If you read a case file created by Fluent/UNS, ANSYS Fluent selects Pressure-Based in the Solver group box of the General Task Page (p. 1888). If you read a case file created by RAMPANT, ANSYS Fluent selects Density-Based in the Solver group box of the General Task Page (p. 1888), as well as Explicit from the Formulation drop-down menu in the Solution Methods Task Page (p. 2204).

Data files created by Fluent/UNS 4 or RAMPANT 4 can be read into ANSYS Fluent in the same way that current data files are read (see Reading and Writing Case and Data Files (p. 47)).

### 3.6. Reading and Writing Profile Files

Boundary profiles are used to specify flow conditions on a boundary zone of the solution domain. For example, they can be used to prescribe a velocity field on an inlet plane. For information on boundary profiles, see Profiles (p. 377). For information about transient profiles, see Defining Transient Cell Zone and Boundary Conditions (p. 388).

For additional information, see the following sections:

- 3.6.1. Reading Profile Files
- 3.6.2. Writing Profile Files

#### 3.6.1. Reading Profile Files

To read the boundary profile files, invoke the Select File dialog box by selecting the File/Read/Profile... menu item.
File → Read → Profile...

This opens the Select File dialog box so that you can read a boundary profile with the standard extension .prof or a transient profile in tabular format with the standard extension .ttab. If a profile in the file has the same name as an existing profile, the old profile will be overwitten.

3.6.2. Writing Profile Files

You can also create a profile file from the conditions on a specified boundary or surface. For example, you can create a profile file from the outlet conditions of one case. Then you can read that profile into another case and use the outlet profile data as the inlet conditions for the new case.

To write a profile file, use the Write Profile Dialog Box (p. 2101) (Figure 3.3: The Write Profile Dialog Box (p. 55)).

File → Write → Profile...

Figure 3.3: The Write Profile Dialog Box

1. Retain the default option of Define New Profiles.

2. Select the surface(s) from which you want to extract data for the profile(s) in the Surfaces list.

3. Choose the variable(s) for which you want to create profiles in the Values list.

4. Click Write... and specify the profile file name in the resulting Select File dialog box.

ANSYS Fluent saves the mesh coordinates of the data points for the selected surface(s) and the values of the selected variables at those positions. When you read the profile file back into Fluent, you can
select the profile values from the relevant drop-down lists in the boundary condition dialog boxes. The names of the profile values in the drop-down lists will consist of the surface name and the particular variable.

5. Select the **Write Currently Defined Profiles** option:
   - if you have made any modifications to the boundary profiles since you read them in (for example, if you reoriented an existing profile to create a new one).
   - if you want to store all the profiles used in a case file in a separate file.

6. Click **Write...** and specify the file name in the resulting **Select File** dialog box. All currently defined profiles are saved in this file. This file can be read back into Fluent whenever you want to use these profiles again.

### 3.7. Reading and Writing Boundary Conditions

To save all currently defined boundary conditions to a file, enter the **file/write-settings** text command and specify a name for the file.

```
file → write-settings
```

ANSYS Fluent writes the boundary and cell zone conditions, the solver, and model settings to a file using the same format as the “zone” section of the case file. See [Case and Data File Formats (p. 2533)](#) for details about the case file format.

To read boundary conditions from a file and to apply them to the corresponding zones in your model, enter the **file/read-settings** text command.

```
file → read-settings
```

ANSYS Fluent sets the boundary and cell zone conditions in the current model by comparing the zone name associated with each set of conditions in the file with the zone names in the model. If the model does not contain a matching zone name for a set of boundary conditions, those conditions are ignored.

If you read boundary conditions into a model that contains a different mesh topology (for example, a cell zone has been removed), check the conditions at boundaries within and adjacent to the region of the topological change. This is important for wall zones.

**Note**

If the boundary conditions are not checked and some remain uninitialized, the case will not run successfully.

When the **file/read-settings** text command is not used, all boundary conditions get the default settings when a mesh file is imported, allowing the case to run with the default values.

If you want ANSYS Fluent to apply a set of conditions to multiple zones with similar names, or to a single zone with a name you are not sure of in advance, you can edit the boundary-condition file saved with the **file/write-settings** command to include wildcards (*) within the zone names. For example, if you want to apply a particular set of conditions to **wall-12**, **wall-15**, and **wall-17** in your current...
model, edit the boundary-condition file so that the zone name associated with the desired conditions is wall-*.  

**Note**

The settings file contains only your user-modified settings and does not include default ANSYS Fluent parameters. The default parameters may be updated with each new release. Consequently, the usage of the same settings file in different releases of ANSYS Fluent does not guarantee the same setup which can cause solution differences.

---

**3.8. Writing a Boundary Mesh**

You can write the boundary zones (surface mesh) to a file. This file can be read and used by the meshing mode of Fluent to produce a volume mesh. You may find this feature useful if you are unsatisfied with a mesh obtained from another mesh generation program.

A boundary mesh can be written using the **Select File** dialog box invoked by selecting the **File/Write/Boundary Mesh...** menu item.

**File → Write → Boundary Mesh...**

**3.9. Reading Scheme Source Files**

A Scheme source file can be loaded in three ways: through the menu system as a scheme file, through the menu system as a journal file, or through Scheme itself.

For large source files, use the **Select File** dialog box invoked by selecting the **File/Read/Scheme...** menu item

**File → Read → Scheme...**

or use the Scheme `load` function in the console, as shown in the following example:

```
> (load "file.scm")
```

Shorter files can also be loaded with the **File/Read/Journal...** menu item or the `file/read-journal` command in the text interface (or its `.source` alias, as shown in the example that follows).

```
> file.scm
> source file.scm
```

In this case, each character of the file is echoed to the console as it is read, in the same way as if you were typing in the contents of the file.

**3.10. Creating and Reading Journal Files**

A journal file contains a sequence of ANSYS Fluent commands, arranged as they would be typed interactively into the program or entered through the GUI or TUI. The GUI and TUI commands are recorded as Scheme code lines in journal files. You can also create journal files manually with a text editor. If you want to include comments in your file, be sure to put a semicolon (`;`) at the beginning of each comment line. See **Background Execution on Linux Systems** in the **Getting Started Guide** for an example.
The purpose of a journal file is to automate a series of commands instead of entering them repeatedly on the command line. Another use is to produce a record of the input to a program session for later reference, although transcript files are often more useful for this purpose. (For details, see Creating Transcript Files (p. 59)).

Command input is taken from the specified journal file until its end is reached, at which time control is returned to the standard input (usually the keyboard). Each line from the journal file is echoed to the standard output (usually the screen) as it is read and processed.

---

**Important**

A journal file is, by design, just a simple record and playback facility. It contains no information about the state in which it was recorded or the state in which it is being played back.

- Be careful not to change the folder while recording a journal file. Also, try to re-create the state in which the journal was written before you read it into the program. For example, if your journal file includes an instruction to save a new file with a specified name, you should check that if a file with that name exists in your folder before you read in your journal file. If a file with that name exists and you read in your journal file, when the program reaches the write instruction, it will prompt for a confirmation to overwrite the old file.

  Since the journal file does not contain any response to the confirmation request, ANSYS Fluent cannot continue to follow the instructions of the journal file.

- Other conditions that may affect the program's ability to perform the instructions contained in a journal file can be created by modifications or manipulations that you make within the program.

  For example, if your journal file creates several surfaces and displays data on those surfaces, you must be sure to read in appropriate case and data files before reading the journal file.

---

**Important**

At a point of time, only one journal file can be open for recording, but you can write a journal and a transcript file simultaneously. You can also read a journal file at any time.

---

Whether you choose to type the text command in full or use partial strings (as described in Command Abbreviation (p. 30)), complete commands are recorded in the journal files. Consider the following examples:

- **Typing in the TUI**

  `solve/set/expert , , yes , ,`

  will be recorded in the journal file as

  `/solve/set/expert yes no yes no no`

  where , or **Enter** signifies default values or entries, as described in Text Prompt System (p. 32).

- **Typing in the TUI**

  `so set ur mom 0.2 pres 0.4`

  will be recorded in the journal file as two separate commands:
Important

• Only successfully completed commands are recorded. For example, if you stopped an execution of a command using Ctrl+c, it will not be recorded in the journal file.

• If a GUI event happens while a text command is in progress, the GUI event is recorded first.

• All default values are recorded (as in the first example above).

For additional information, see the following section:

3.10.1. Procedure

3.10.1. Procedure

To start the journaling process, select the File/Write/Start Journal... menu item.

File → Write → Start Journal...

After you enter a name for the file in the Select File dialog box, journal recording begins. The Start Journal... menu item becomes the Stop Journal menu item. You can end journal recording by selecting Stop Journal, or by exiting the program.

File → Write → Stop Journal

You can read a journal file into the program using the Select File dialog box invoked by selecting the File/Read/Journal... menu item.

File → Read → Journal...

Journal files are always loaded in the main (that is, top-level) text menu, regardless of where you are in the text menu hierarchy when you invoke the read command.

3.11. Creating Transcript Files

A transcript file contains a complete record of all standard input to and output from ANSYS Fluent (usually all keyboard and GUI input and all screen output). GUI commands are recorded as Scheme code lines in transcript files. ANSYS Fluent creates a transcript file by recording everything typed as input or entered through the GUI, and everything printed as output in the text window.

The purpose of a transcript file is to produce a record of the program session for later reference. Because they contain messages and other output, transcript files (unlike journal files), cannot be read back into the program.

Important

Only one transcript file can be open for recording at a time, but you can write a transcript and a journal file simultaneously. You can also read a journal file while a transcript recording is in progress.
To start the transcription process, select the **File/Write/Start Transcript...** menu item.

**File → Write → Start Transcript...**

After you enter a name for the file in the **Select File** dialog box, transcript recording begins and the **Start Transcript...** menu item becomes the **Stop Transcript** menu item.

You can end transcript recording by selecting **Stop Transcript**, or by exiting the program.

**File → Write → Stop Transcript**

### 3.12. Importing Files

ANSYS Fluent allows you to import the following file formats:

- ABAQUS `.inp`, `.fil`, and `.odb` files
- CFX `.def` and `.res` files
- CGNS files
- EnSight files
- ANSYS FIDAP files
- GAMBIT files
- HYPERMESH ASCII files
- I-deas Universal files
- LSTC/DYNA keyword input files and state databases
- Marc POST files
- Mechanical APDL `.inp`, `.cdb`, `.rst`, `.rgm`, and `.rfl` files.
- NASTRAN Bulk Data files
- PATRAN Neutral files
- PLOT3D mesh files
- PTC Mechanica Design studies
- Tecplot files
For information on importing particle history data, see Importing Particle Data (p. 1218).

For additional information, see the following sections:

3.12.1. ABAQUS Files
3.12.2. CFX Files
3.12.3. Meshes and Data in CGNS Format
3.12.4. EnSight Files
3.12.5. ANSYS FIDAP Neutral Files
3.12.6. GAMBIT and GeoMesh Mesh Files
3.12.7. HYPERMESH ASCII Files
3.12.8. I-deas Universal Files
3.12.9. LSTC Files
3.12.10. Marc POST Files
3.12.11. Mechanical APDL Files
3.12.12. NASTRAN Files
3.12.13. PATRAN Neutral Files
3.12.14. PLOT3D Files
3.12.15. PTC Mechanica Design Files
3.12.16. Tecplot Files
3.12.17. Fluent 4 Case Files
3.12.18. PreBFC Files
3.12.19. Partition Files
3.12.20. CHEMKIN Mechanism
3.12.1. ABAQUS Files

To import an ABAQUS input file, use the File/Import/ABAQUS/Input File... menu item.

File → Import → ABAQUS → Input File...

Select this menu item to open the Select File dialog box. Specify the name of the ABAQUS Input File to be read. The ABAQUS input file (.inp) is a text file that contains the input description of a finite element model for the ABAQUS finite element program. The interface only produces datasets associated with the finite element model, no results of datasets are produced. Element types commonly associated with structural analysis are supported by this file format. There is a list of input keywords that are recognized in the ABAQUS Input File [3] (p. 2557).

To import an ABAQUS filbin file, use the File/Import/ABAQUS/Filbin File... menu item.

File → Import → ABAQUS → Filbin File...

Select this menu item to open the Select File dialog box. Specify the name of the ABAQUS Filbin File to be read. This output file has a .fil extension and consists of finite element model and results data.

To import an ABAQUS ODB file, use the File/Import/ABAQUS/ODB File... menu item.

File → Import → ABAQUS → ODB File...

Select this menu item to open the Select File dialog box. Specify the name of the ABAQUS ODB File to be read. This output database file has a .odb extension and consists of finite element model and results data in the OpenDocument format.

3.12.2. CFX Files

To import a CFX definition file, use the File/Import/CFX/Definition File... menu item.

File → Import → CFX → Definition File...

Select this menu item to invoke the Select File dialog box. Specify the name of the CFX Definition File to be read. Fluent reads mesh information from the CFX file with .def extensions. For information about importing CFX files, see CFX Files (p. 139).

To import a CFX result file, use the File/Import/CFX/Result File... menu item.

File → Import → CFX → Result File...

In the Select File dialog box, specify the name of the CFX Result File to be read. Those imported files will have .res extensions.

Note that the Create Zones from CCL Physics Data option in the Select File dialog boxes allows you to create zones from the physics data objects or the primitive mesh region objects.

---

Important

CFX file import is available for 3D cases only.
3.12.3. Meshes and Data in CGNS Format

To import meshes in CFD general notation system (CGNS) format (.cgns) into ANSYS Fluent, use the File/Import/CGNS/Mesh... menu item.

File → Import → CGNS → Mesh...

To import a mesh and the corresponding CGNS data, use the File/Import/CGNS/Mesh & Data... menu item.

File → Import → CGNS → Mesh & Data...

To import only the CGNS data, use the File/Import/CGNS/Data... menu item.

File → Import → CGNS → Data...

Table 3.3: CGNS Variables Supported by ANSYS Fluent

<td>y-velocity</td>
</tr>
<tr>
<td>VelocityZ</td>
<td>z-velocity</td>
</tr>
</tbody>
</table>

Important

- To import data correctly, first import the mesh using the mesh only option (Mesh...) and set up the boundary conditions. For example, if a boundary zone is of type pressure-outlet and is read as outlet, it should be changed to pressure-outlet before importing the data. Then select the appropriate model and read the data using the data only option (Data...)

- The new and original meshes should have the same zones, numbered in the same order. A warning is issued if they do not, because inconsistencies can create problems with the boundary conditions.

- ANSYS Fluent defaults to the Laminar Viscous Model after reading a CGNS mesh. You must select the appropriate model before reading data since ANSYS Fluent selectively
imports only those values from the CGNS file required for a given model. For example, if Epsilon is available in the CGNS file, the model must be changed to k-epsilon to ensure that ANSYS Fluent will import this quantity.

### 3.12.4. EnSight Files

You can import an EnSight file using the File/Import/EnSight... menu item.

File → Import → EnSight...

This file format is applied to both unstructured and structured data, where each part contains its own local coordinate array. The EnSight Gold software package, which uses this file format, allows you to analyze, visualize, and communicate engineering datasets. It allows you to take full advantage of parallel processing and rendering and supports a range of virtual reality devices. Furthermore, it enables real-time collaboration.

When selecting this option, the Select File dialog box will appear, where you will specify a file name. This file will have an .encas or .case extension.

Only the mesh file is read into ANSYS Fluent, and any data present is discarded.

### 3.12.5. ANSYS FIDAP Neutral Files

You can read an ANSYS FIDAP neutral file using the File/Import/FIDAP... menu item.

File → Import → FIDAP...

In the Select File dialog box, specify the name of the ANSYS FIDAP Neutral File to be read. This file will have an .FDNEUT or .unv file extension. ANSYS Fluent reads mesh information and zone types from the ANSYS FIDAP file. You must specify boundary conditions and other information after reading this file. For information about importing ANSYS FIDAPNeutral files, see ANSYS FIDAP Neutral Files (p. 143).

### 3.12.6. GAMBIT and GeoMesh Mesh Files

If you have saved a neutral file from GAMBIT, rather than an ANSYS Fluent mesh file, you can import it into ANSYS Fluent using the File/Import/GAMBIT... menu item.

File → Import → GAMBIT...

For information about importing files from GAMBIT and GeoMesh, see GAMBIT Mesh Files (p. 134) and GeoMesh Mesh Files (p. 134).

### 3.12.7. HYPERMESH ASCII Files

You can read a HYPERMESH ASCII file using the File/Import/HYPERMESH ASCII... menu item.

File → Import → HYPERMESH ASCII...

HYPERMESH is a high-performance finite element pre- and postprocessor for popular finite element solvers, allowing engineers to analyze product design performance in a highly interactive and visual environment.
When selecting this option, the Select File dialog box will appear, where you will specify a file name. This file should have an .hm, .hma, or .hmascii extension.

### 3.12.8. I-deas Universal Files

I-deas Universal files can be read into ANSYS Fluent with the File/Import/I-deas Universal... menu item.

**File → Import → I-deas Universal...**

Select the I-deas Universal... menu item to invoke the Select File dialog box.

Specify the name of the I-deas Universal file to be read. Fluent reads mesh information and zone types from the I-deas Universal file. For information about importing I-deas Universal files, see I-deas Universal Files (p. 135).

### 3.12.9. LSTC Files

To import an LSTC input file, use the File/Import/LSTC/Input File... menu item.

**File → Import → LSTC → Input File...**

The LSTC input file is a text file that contains the input description of a finite element model for the LS-DYNA finite element program. This interface only produces datasets associated with the mesh, no results datasets are produced. The element types commonly associated with structural analysis are supported.

LSTC input files have the following file extensions: .k, .key, and .dyn

To import an LSTC state file, use the File/Import/LSTC/State File... menu item.

**File → Import → LSTC → State File...**

The state file consists of three major sections: control data, geometry data, and state data. Each dataset in the state data section corresponds to the time and global data items associated with each state on the database. Dataset attributes include such things as time, energy, and momentum.

An LSTC state file has a .d3plot file extension.

### 3.12.10. Marc POST Files

Marc POST files can be read into ANSYS Fluent using the File/Import/Marc POST... menu item.

**File → Import → Marc POST...**

Select the Marc POST... menu item and in the Select File dialog box, specify the name of the file to be read.

These files are generated using MSC Marc, a nonlinear finite element program. MSC Marc allows you to study deformations that exceed the linear elastic range of some materials, enabling you to assess the structural integrity and performance of the material. It also allows you to simulate deformations that are part-to-part or part-to-self contact under a range of conditions.
3.12.11. Mechanical APDL Files

To import a Mechanical APDL input file, use the File/Import/Mechanical APDL/Input File... menu item.

File → Import → Mechanical APDL → Input File...

Select this menu item to invoke the Select File dialog box. Specify the name of the Mechanical APDL Prep7 File to be read. Fluent reads mesh information from the Mechanical APDL file with .ans, .neu, .cdb, and .prep7 extensions. For information about importing Mechanical APDL files, see Mechanical APDL Files (p. 139).

To import a Mechanical APDL result file, use the File/Import/Mechanical APDL/Result File... menu item.

File → Import → Mechanical APDL → Result File...

In the Select File dialog box. Specify the name of the Mechanical APDL Result File to be read. Those imported files will have .rfl, .rst, .rth, and .rmg extensions.

3.12.12. NASTRAN Files

You can read NASTRAN Bulkdata files into ANSYS Fluent with the File/Import/NASTRAN/Bulkdata File... menu item.

File → Import → NASTRAN → Bulkdata File...

When you select the Bulkdata File... menu item, the Select File dialog box will appear and you will specify the name of the NASTRAN File to be read. This file will have .nas, .dat, .bdf file extensions. Fluent reads mesh information from the NASTRAN file. For information about importing NASTRAN files, see NASTRAN Files (p. 136).

To import NASTRAN Op2 files into ANSYS Fluent, use the File/Import/NASTRAN/Op2 File... menu item.

File → Import → NASTRAN → Op2 File...

In the Select File dialog box, specify the name of the NASTRAN Output2 File to be read. This file is an output binary data file that contains data used in the NASTRAN finite element program. This file will have .op2 file extension.

3.12.13. PATRAN Neutral Files

To read a PATRAN Neutral file zoned by named components (that is, a file in which you have grouped nodes with the same specified group name), use the File/Import/PATRAN Neutral... menu item.

File → Import → PATRAN Neutral...

Selecting this menu item invokes the Select File dialog box. Specify the name of the PATRAN Neutral file to be read (extension .neu, .out, or .pat). Fluent reads mesh information from the PATRAN Neutral file. For information about importing PATRAN Neutral files, see PATRAN Neutral Files (p. 137).

3.12.14. PLOT3D Files

To import a PLOT3D mesh file, use the File/Import/PLOT3D Grid... menu item.
3.12.15. PTC Mechanica Design Files

To import a PTC Mechanica Design file, use the File/Import/PTC Mechanica Design... menu item.

File → Import → PTC Mechanica Design...

This will open the Select File dialog box. Specify the name of the neutral file to be read.

The PTC Mechanica Design file contains analysis, model and results data. Only the binary form of the results data files is supported.

The form of the file must have the .neu extension.

---

Important

Mechanica results consists of an entire directory structure of files, called a “study” in Mechanica terminology, which must be used in exactly the form that Mechanica originally generates it. ANSYS Fluent’s VKI interface keys on the .neu file and can traverse the directory structure from there to access the other files that it needs.

3.12.16. Tecplot Files

To import a Tecplot file, use the File/Import/Tecplot... menu item.

File → Import → Tecplot...

This will open the Select File dialog box. Specify the name of the neutral file to be read.

The Tecplot file is a binary file. Only the mesh is read into ANSYS Fluent and any data present is discarded.

The form of the file must have the .plt extension. ANSYS Fluent supports the importation of polyhedral cells and files created by Tecplot version 7.1–11.2, except for version 11.0 (which is unsupported).

3.12.17. Fluent 4 Case Files

You can read a Fluent 4 case file using the File/Import/Fluent 4 Case File... menu item.

File → Import → Fluent 4 Case File...

Select the Fluent 4 Case File... menu item to invoke the Select File dialog box. Specify the name of the Fluent 4 case file to be read. ANSYS Fluent reads only mesh information and zone types from the Fluent 4 case file. You must specify boundary and cell zone conditions, model parameters, material properties, and other information after reading this file. For information about importing Fluent 4 case files, see Fluent 4 Case Files (p. 143).
3.12.18. PreBFC Files

You can read a PreBFC structured mesh file into ANSYS Fluent using the **File/Import/PreBFC File...** menu item.

File → Import → PreBFC File...

Select the **PreBFC File...** menu item to invoke the **Select File** dialog box. Specify the name of the PreBFC structured mesh file to be read. Fluent reads mesh information and zone types from the PreBFC mesh file. For information about importing PreBFC mesh files, see **PreBFC Mesh Files (p. 134)**.

3.12.19. Partition Files

To perform METIS partitioning on an unpartitioned mesh, use the **File/Import/Partition/Metis...** menu item.

File → Import → Partition → Metis...

You may also partition each cell zone individually, using the **File/Import/Partition/Metis Zone...** menu item.

File → Import → Partition → Metis Zone...

See **Using the Partition Filter (p. 1874)** for detailed information about partitioning.

3.12.20. CHEMKIN Mechanism

To import a CHEMKIN format, you can import the mechanism file into ANSYS Fluent using the **File/Import/CHEMKIN Mechanism...** menu item (**Figure 15.12: The CHEMKIN Mechanism Import Dialog Box for Volumetric Kinetics (p. 916)**).

File → Import → CHEMKIN Mechanism...

See **Importing a Volumetric Kinetic Mechanism in CHEMKIN Format (p. 915)** for detailed information on importing a CHEMKIN Mechanism file.

3.13. Exporting Solution Data

The current release of ANSYS Fluent allows you to export data to ABAQUS, Mechanical APDL, Mechanical APDL Input, ASCII, AVS, ANSYS CFD-Post, CGNS, Data Explorer, EnSight, FAST, FIELDVIEW, I-deas, NASTRAN, PATRAN, RadTherm, and Tecplot formats. **Exporting Solution Data after a Calculation (p. 70)** explains how to export solution data in these formats after the calculation is complete, and **ABAQUS Files (p. 71)** to **Tecplot Files (p. 82)** provide specific information for each type of **File Type**. For information about exporting solution data during transient flow solutions, see **Exporting Data During a Transient Calculation (p. 84)**.

For NASTRAN, ABAQUS, Mechanical APDL Input, I-deas Universal, and PATRAN file formats, the following quantities are exported [3] (p. 2557):

- Nodes, Elements
- Node Sets (Boundary Conditions)
- Temperature
• Pressure
• Heat Flux
• Heat Transfer Coefficient
• Force

To generate the force data that is exported for nodes at boundaries, ANSYS Fluent performs the following steps:

1. Facial force for each wall face is calculated by summing the pressure force, viscous force and surface tension force of the face.

2. Partial force for each wall face is calculated by dividing its facial force by its number of shared nodes.

3. Total force for each wall node is calculated by summing the partial forces of all the wall faces sharing that node.

For additional information, see the following section:

3.13.1. Exporting Limitations

3.13.1. Exporting Limitations

Note the following limitations when exporting solution data:

• When using the parallel version of ANSYS Fluent, you can only export to the following packages:
  – ABAQUS
  – ANSYS CFD-Post
  – ASCII
  – CGNS
  – EnSight Case Gold
  – Fieldview Unstructured
  – I-deas Universal
  – Mechanical APDL Input
  – NAStRAN
  – PATRAN
  – Tecplot

The exported file will be written by the host process (see Introduction to Parallel Processing (p. 1833)). Note that the memory required to write the file may exceed the memory available to the host process.

• When using the parallel version of ANSYS Fluent, the only packages to which you can export custom field functions are the following:
For further information about custom field functions, see Custom Field Functions (p. 1826).

- The solution mode of Fluent cannot import surfaces. Consequently, if you export a file from ANSYS Fluent with surfaces selected, you may not be able to read these files back into the solution mode. However, the meshing mode of Fluent can import surface data (see the Fluent Meshing User’s Guide for details).

- ANSYS Fluent supports exporting polyhedral data only for ASCII, ANSYS CFD-Post, EnSight Case Gold, RadTherm, Tecplot and Fieldview Unstructured file formats. For further details, see ASCII Files (p. 73), ANSYS CFD-Post-Compatible Files (p. 74), EnSight Case Gold Files (p. 76), RadTherm Files (p. 81) and Fieldview Unstructured Files (p. 79).

- If the files that are exported during multiple transient simulations are to be used as a set, you must make sure that all of the simulations are run on the same platform, using the same number of processors. This ensures that all of the files are compatible with each other.

### 3.14. Exporting Solution Data after a Calculation

To export solution data to a different file format after a calculation is complete, use the Export Dialog Box (p. 2386) (Figure 3.5: The Export Dialog Box (p. 70)).

File → Export → Solution Data...

**Figure 3.5: The Export Dialog Box**
Information concerning the necessary steps and available options for each File Type are listed in ABAQUS Files (p. 71) to Tecplot Files (p. 82).

For details about general limitations for exporting solution data and the manner in which it is exported, see Exporting Solution Data (p. 68).

For additional information, see the following sections:

3.14.1. ABAQUS Files
3.14.2. Mechanical APDL Files
3.14.3. Mechanical APDL Input Files
3.14.4. ASCII Files
3.14.5. AVS Files
3.14.6. ANSYS CFD-Post-Compatible Files
3.14.7. CGNS Files
3.14.8. Data Explorer Files
3.14.9. EnSight Case Gold Files
3.14.10. FAST Files
3.14.11. FAST Solution Files
3.14.13. I-deas Universal Files
3.14.14. NASTRAN Files
3.14.15. PATRAN Files
3.14.16. RadTherm Files
3.14.17. Tecplot Files

3.14.1. ABAQUS Files

Select ABAQUS from the File Type drop-down list and choose the surface(s) for which you want to write data in the Surfaces list. If no surfaces are selected, the entire domain is exported.

When the Energy Equation is enabled in the Energy Dialog Box (p. 1903), you can choose the loads to be written based on the kind of finite element analysis you intend to undertake. By selecting Structural in the Analysis list, you can select the following Structural Loads: Force, Pressure, and Temperature. By selecting Thermal in the Analysis list, you can select the following Thermal Loads: Temperature, Heat Flux, and Heat Trans Coeff. Note the following limitations with these loads:

- When the Energy Equation is disabled, only the Structural Loads options of Force and Pressure are available.
- Loads are written only on boundary walls when the entire domain is exported (that is, if no Surfaces are selected).

Click the Write... button to save the file, using the Select File dialog box. The exported file format of ABAQUS (file.inp) contains coordinates, connectivity, zone groups, and optional loads.

Export of data to ABAQUS is valid only for solid zones or for those surfaces that lie at the intersection of solid zones. Temperature data is exported for the whole domain.

You have the option of exporting data at specified intervals during a transient calculation through the Automatic Export dialog box. See Exporting Data During a Transient Calculation (p. 84) for the complete details.
3.14.2. Mechanical APDL Files

Export to Mechanical APDL can only be invoked using the `file/export/mechanical-apdl` text command. You will be prompted to enter a Mechanical APDL file name and the Zone to Export.

The file written is a Mechanical APDL results file with a `.rfl` extension. This file preserves the cell zones defined in ANSYS Fluent. The Mechanical APDL file is a single file containing coordinates, connectivity, and the scalars listed below:

```
'x-velocity', 'y-velocity', 'z-velocity', 'pressure',
'temperature', 'turb-kinetic-energy', 'turb-diss-rate',
'density', 'viscosity-turb', 'viscosity-lam', 'viscosity-eff',
'thermal-conductivity-lam', 'thermal-conductivity-eff',
'total-pressure', 'total-temperature', 'pressure-coefficient',
mach-number', 'stream-function', 'heat-flux',
'heat-transfer-coef', 'wall-shear', 'specific-heat-cp'
```

**Important**

Export to ANSYS is available on a limited number of platforms (ntx86).

To read this file into Mechanical APDL, do the following:

1. In Mechanical APDL, expand the `General Postproc` item in the ANSYS Main Menu, and click Data & FileOpts. Then perform the following steps in the Data and File Options dialog box that opens.
   a. Make sure that Read single result file is selected.
   b. Click the Browse... button to open the Open dialog box, and select the `.rfl` file generated by ANSYS Fluent.
   c. Click Open in the Open dialog box.
   d. Click OK in the Data and File Options dialog box.

2. In the ANSYS Main Menu, click Results Summary in the expanded General Postproc list. A SET,LIST Command window will open, displaying a summary of the file contents.

3. In the expanded General Postproc list, expand the Read Results item and click First Set to read the data from the file.

4. Display the data from the file. You can display mesh information by selecting either the Plot/Nodes menu item or the Plot/Elements menu item from the Mechanical APDL menu bar. You can display results by selecting either the Plot/Results/Contour Plot/Nodal Solution... menu item or the Plot/Results/Contour Plot/Elem Solution... menu item, and then using the dialog box that opens.

You have the option of using the Execute Commands dialog box to export data to Mechanical APDL at specified intervals during the calculation. The text command for exporting can be entered directly into the Command text box (or the ANSYS Fluent console, if you are defining a macro). It is of the following form:

```
file/export/mechanical-apdl file_name list_of_cell_zones ()
```

where
• `file_name` specifies the name (without the extension) of the file that you want to write. You should include a special character string in the file name, so that Fluent assigns a new name to each file it saves. For details, see Automatic Numbering of Files (p. 45). By using a special character string, you can have the files numbered by time step, flow time, etc.

• `list_of_cell_zones` specifies the list of cell zones (separated by commas) from which you want to export data. The () input terminates the list. For example, the input `fluid-rotor, fluid-stator()` will select the cell zones named `fluid-rotor` and `fluid-stator`.

See Executing Commands During the Calculation (p. 1501) for information about executing commands and creating and using command macros.

### 3.14.3. Mechanical APDL Input Files

Select Mechanical APDL Input from the `File Type` drop-down list and choose the surface(s) for which you want to write data in the `Surfaces` list. If no surfaces are selected, the entire domain is exported.

When the `Energy Equation` is enabled in the Energy Dialog Box (p. 1903), you can choose the loads to be written based on the kind of finite element analysis you intend to undertake. By selecting `Structural` in the `Analysis` list, you can select the following `Structural Loads`: Force, Pressure, and Temperature. By selecting `Thermal` in the `Analysis` list, you can select the following `Thermal Loads`: Temperature, Heat Flux, and Heat Trans Coeff. Note the following limitations with these loads:

• When the `Energy Equation` is disabled, only the `Structural Loads` options of Force and Pressure are available.

• Loads are written only on boundary walls when the entire domain is exported (that is, if no `Surfaces` are selected).

Click the Write... button to save the file, using the `Select File` dialog box. ANSYS Fluent exports an input file that contains Mechanical APDL finite element information including nodes, elements, and loads that can be used to do finite element analysis in Mechanical APDL with minimal effort. The file format is written in `.cde` format. The export of Mechanical APDL Input files is in ASCII format and therefore is available on all platforms.

You have the option of exporting data at specified intervals during a transient calculation through the Automatic Export dialog box. See Exporting Data During a Transient Calculation (p. 84) for the complete details.

### 3.14.4. ASCII Files

Select ASCII from the `File Type` drop-down list and choose the surface(s) for which you want to write data in the `Surfaces` list. If no surfaces are selected, the entire domain is exported. Also select the variable(s) for which data is to be saved in the `Quantities` list.

When exporting ASCII files, you have the following options:

• Select the `Location` from which the values of scalar functions are to be taken. If you specify the data Location as Node, then the data values at the node points are exported. If you choose Cell Center, then the data values from the cell centers are exported. For boundary faces, it is the face center values that are exported when the Cell Center option is selected.

• Select the `Delimiter` separating the fields (Comma or Space).
Click the **Write...** button to save the file, using the **Select File** dialog box. ANSYS Fluent will export a single ASCII file containing coordinates, optional loads, and specified scalar function data.

### Important
ANSYS Fluent supports exporting polyhedral data to ASCII.

You have the option of exporting data at specified intervals during a transient calculation through the **Automatic Export** dialog box. See Exporting Data During a Transient Calculation (p. 84) for the complete details.

#### 3.14.5. AVS Files

Select **AVS** from the **File Type** drop-down list and specify the scalars you want in the **Quantities** list.

Click the **Write...** button to save the file, using the **Select File** dialog box. An AVS version 4 UCD file contains coordinate and connectivity information and specified scalar function data.

You have the option of exporting data at specified intervals during a transient calculation through the **Automatic Export** dialog box. See Exporting Data During a Transient Calculation (p. 84) for the complete details.

#### 3.14.6. ANSYS CFD-Post-Compatible Files

To export data to files that are compatible with ANSYS CFD-Post, select **CFD-Post Compatible** from the **File Type** drop-down list. Next, specify the cell zones from which you want data exported by making selections in the **Cell Zones** list (you must select at least one zone); note that by default, all of the cell zones will be exported. Then select the variables for which you want data saved from the **Quantities** selection list. When selecting the variables, be sure to include any variable that was used to create an isosurface or clipped surface (as described in Isosurfaces (p. 1595) and Clipping Surfaces (p. 1597), respectively); otherwise, the surface will not be created properly if you try to read the exported state file in CFD-Post.

Specify the format of the **.cdat** file by selecting either **Binary** or **ASCII** from the **Format** list. The advantage of the binary format is that it takes less time to load the exported data into ANSYS CFD-Post and requires less storage space. Note that the format for the **.cst** will always be ASCII.

By default, Fluent will write a case file (that is, **.cas**) along with the **CFD-Post Compatible** files. If you do not want such a case file for any reason (for example, to improve I/O performance or save disc space), disable the **Write Case File** option. Disabling this option is only recommended if you are performing multiple export operations for a case file that is not changing.

Click the **Write...** button to save the files, using the **Select File** dialog box. A **.cdat** file is written, containing the specified variable data for the specified cell zones and all of the boundary zones. A state file (that is, **.cst**) is also written, which contains the following surfaces that you created in Fluent for postprocessing: point surfaces, line surfaces, plane surfaces, isosurfaces, and clipped surfaces (see Creating Surfaces for Displaying and Reporting Data (p. 1579)).

### Important
When you read the **.cdat** file into ANSYS CFD-Post, the application will attempt to read in the case file that produced the data by looking in the folder for a **.cas** file with the same
prefix. If the case file is not in that folder (e.g., if you disabled the Write Case File option when exporting), ANSYS CFD-Post will prompt you to specify the appropriate case file.

---

**Important**

Before loading the .cst file into ANSYS CFD-Post, make sure that the .cas and .cdat files are already loaded for the session.

You have the option of exporting data at specified intervals during a transient calculation through the Automatic Export dialog box. See Exporting Data During a Transient Calculation (p. 84) for the complete details.

### 3.14.7. CGNS Files

Select CGNS from the File Type drop-down list and specify the scalars you want in the Quantities list.

Select the Location from which the values of scalar functions are to be taken. If you specify the data Location as Node, then the data values at the node points are exported. If you choose Cell Center, then the data values from the cell centers are exported. For boundary faces, it is the face center values that are exported when the Cell Center option is selected.

Click the Write... button to save the file, using the Select File dialog box. CGNS (CFD general notation system) is a single file (for example, file.cgns) containing coordinates, connectivity, zone information, velocity, and selected scalars.

You have the option of exporting data at specified intervals during a transient calculation through the Automatic Export dialog box. See Exporting Data During a Transient Calculation (p. 84) for the complete details.

### 3.14.8. Data Explorer Files

Select Data Explorer from the File Type drop-down list and choose the surface(s) for which you want to write data in the Surfaces list. If no surfaces are selected, the entire domain is exported. Also specify the scalars you want in the Quantities list.

---

**Important**

When you are exporting data for Data Explorer, EnSight Case Gold, or I-deas Universal and the reference zone is not a stationary zone, the data in the velocity fields is exported by default as velocities relative to the motion specification of that zone. This data is always exported, even if you do not choose to export any scalars. Any velocities that you select to export as scalars in the Quantities list (for example, X Velocity, Y Velocity, Radial Velocity, etc.) are exported as absolute velocities. For all other types of exported files, the velocities exported by default are absolute velocities.

Click the Write... button to save the file, using the Select File dialog box. A single file (for example, file.dx) is exported, containing coordinate, connectivity, velocity, and specified function data.

You have the option of exporting data at specified intervals during a transient calculation through the Automatic Export dialog box. See Exporting Data During a Transient Calculation (p. 84) for the complete details.
3.14.9. EnSight Case Gold Files

When exporting to EnSight, you can choose to export the data associated with a single data file, or you can export the data associated with multiple files that were generated by a transient solution.

- To export the solution data from a single data file, read in the case and data file and open the Export dialog box.

  File → Export → Solution Data...

  Then perform the following steps in the Export dialog box:

  1. Select EnSight Case Gold from the File Type drop-down list.

  2. Select the Location from which the values of scalar functions are to be taken. If you specify the data Location as Node, then the data values at the node points are exported. If you choose Cell Center, then the data values from the cell centers are exported. For boundary faces, it is the face center values that are exported when the Cell Center option is selected.

  3. Specify the format of the file by selecting either Binary or ASCII from the Format list. The advantage of the binary format is that it takes less time to load the exported files into EnSight.

  4. (optional) Select the Cell Zones from which you want data exported (you must select at least one zone). By default, all of the cell zones are selected.

  5. (optional) Select the Interior Zone Surfaces from which you want data exported. By default, the data being exported is taken from the entire ANSYS Fluent domain. The Interior Zone Surfaces selection list allows you to also specify that the data be taken from selected zone surfaces whose Type is identified as interior in the Boundary Conditions task page.

  6. Select the scalars you want to write from the Quantities selection list.

  7. Click the Write... button to open the Select File dialog box, which you can use to save a file that contains the specified variable data for the specified cell zones, the specified interior zone surfaces, and all of the boundary zones.

- To export solution data associated with multiple files that were generated by a transient solution, you must first make sure that the following criteria are met:
  - All of the relevant case and data files must be in the working folder.
  - The data files must be separated by a consistent number of time steps.

Next, enter the following text command in the console:

file → transient-export → ensight-gold-from-existing-files

Then, enter responses to the following prompts in the console:

1. EnSight Case Gold file name

   Enter the name you want assigned to the exported files.

2. Case / Data file selection by base name?
Enter **yes** if the case and data files share a “base name” (that is, a common initial string of characters). The alphanumeric order of the full names must correspond to the order in which the files were created. You will then be prompted to enter the base name at the **Case / Data file base name** prompt that follows. For example, with a set of files named *elbow-0001*, *elbow-0002*, *elbow-0003*, etc., enter *elbow-* for the base name.

Enter **no** if you have created an ASCII file in the working folder that lists the names of the data files in order of when they were created. The file should list one data file name per line. You will then be prompted to enter the name of this file at the **Provide the file name which contains the data file names** prompt that follows. Note that you must include the file extension if any in your entry at the prompt.

3. **Specify Skip Value**

Enter an integer value to specify the number of files you want to skip in between exporting files from the sequence. For example, enter 1 to export every other file, enter 2 to export every third file, etc.

4. **Cell-Centered?**

Enter **yes** if you want to export the data values from the cell centers (or face center values, for boundary faces).

Enter **no** if you want to export the data values from the node points.

5. **Write separate file for each time step for each variable?**

Enter **yes** if you want separate EnSight Case Gold files written for each time step. Otherwise, all of the data for the *.scl1* and *.vel* files will be combined into a single file for each.

6. **Write in binary format?**

Enter **yes** to write the files in binary format. Otherwise, they will be written in ASCII format. The advantage of the binary format is that it takes less time to load the exported files into EnSight.

7. **Specify Data File Frequency**

Enter the number of time steps between the data files being exported.

8. **Separate case file for each time step?**

Enter **no** if all the data files were generated from the same case file (that is, the simulation involved a static mesh). Note that the name of the case file must be the same (not including the extension) as the name of the first data file in the sequence.

Enter **yes** if the data files were generated from the different case files (that is, the simulation involved a sliding or dynamic mesh). Note that the names of the case files must be the same (not including the extension) as the names of the corresponding data files.

9. **Read the case file?**

Enter **no** if the first (or only, for a static mesh) case file is already in memory.

Enter **yes** if the first (or only, for a static mesh) case file is not already in memory.
10. Cell zone id/name(1)

Enter the name or ID of any cell zone from which you want data exported. By default, the data being exported is taken from the entire ANSYS Fluent domain. After you specify the first cell zone, you will be prompted to specify the second one, and so on, until you press Enter without typing any characters.

11. Interior Zone Surfaces(1)

Enter the name of any interior zone surface from which you want data exported. By default, the data being exported is taken from the entire ANSYS Fluent domain. This prompt allows you to also specify that the data be taken from selected zone surfaces whose Type is identified as interior in the Boundary Conditions task page. After you specify the first interior zone surface, you will be prompted to specify the second one, and so on, until you press Enter without typing any characters.

12. EnSight Case Gold scalar(1) else q to continue

Enter in the first scalar quantity you want exported. You can press the Enter key to print a list of available scalar quantities in the console. After you enter the first quantity, you will be prompted to enter the second quantity, and so on, until you enter q. The EnSight Case Gold files will then be written.

When exporting to EnSight Case Gold, files will be created with the following four formats:

- A geometry file (for example, file.geo) containing the coordinates and connectivity information.
- A velocity file (for example, file.vel) containing the velocity.
- A scalar file (for example, file.scl1) for each selected variable or function.
- An EnSight case file (for example, file.encas) that contains details about the other exported files.

Important

- For non-stationary reference zones, all the velocities are exported to EnSight as velocities relative to the selected reference zone. See the informational note in Data Explorer Files (p. 75) for further details.
- ANSYS Fluent supports exporting polyhedral data to EnSight.

You also have the option of exporting data at specified intervals during a transient calculation through the Automatic Export dialog box. For details, see Exporting Data During a Transient Calculation (p. 84).

3.14.10. FAST Files

This file type is valid only for triangular and tetrahedral meshes. Select FAST from the File Type drop-down list and select the scalars you want to write in the Quantities list.

Click the Write... button to save the file for the specified function(s), using the Select File dialog box. The following files are written:

- A mesh file in extended Plot3D format containing coordinates and connectivity.
• A velocity file containing the velocity.

• A scalar file for each selected variable or function.

You have the option of exporting data at specified intervals during a transient calculation through the **Automatic Export** dialog box. See *Exporting Data During a Transient Calculation* (p. 84) for the complete details.

### 3.14.11. FAST Solution Files

This file type is valid only for triangular and tetrahedral meshes. Select **FAST Solution** from the **File Type** drop-down list and click the **Write...** button. A single file is written containing density, velocity, and total energy data.

You have the option of exporting data at specified intervals during a transient calculation through the **Automatic Export** dialog box. See *Exporting Data During a Transient Calculation* (p. 84) for the complete details.

### 3.14.12. Fieldview Unstructured Files

Select **Fieldview Unstructured** from the **File Type** drop-down list. Next, specify the cell zones from which you want data exported by making selections in the **Cell Zones** list (you must select at least one zone); note that by default, all of the cell zones will be exported. Then select the scalars you want to write in the **Quantities** list. Finally, click the **Write...** button to open the **Select File** dialog box, which you can use to save a file that contains the specified function(s) for the specified cell zones and associated boundary zones.

The following files are written:

• A binary file (for example, *file.fvuns*) containing coordinate and connectivity information and specified scalar function data.

• A regions file (for example, *file.fvuns.fvreg*) containing information about the cell zones and the frame of reference.

The cell zone information includes the names of the cell zones along with the mesh numbers. For the moving frame of reference, the regions file contains information about the origin, the axis of rotation and the rotation speed. Volume data is written using the absolute frame of reference.

If you are running multiple steady-state solutions on the same mesh, you can export only the data files and avoid the repeated writing of the mesh file by using the following TUI command:

```
file/export/fieldview-unstruct-data file_name (list_of_zones) list_of_scalars q
```

where

• **file_name** specifies the name (without the extension) of the file that you want to write.

• **list_of_zones** specifies the list of cell zones (separated by spaces, that is, no commas) from which you want data exported. If you want to specify all of the cell zones, enter * within the parentheses.

• **list_of_scalars** specifies the list of cell functions (separated by spaces, that is, no commas) that you want to write to the exported file. The q input terminates the list. For example, the input x-velocity cell-zone q will select x velocity and the cell volume.
You have the option of exporting data at specified intervals during a transient calculation through the Automatic Export dialog box. See Exporting Data During a Transient Calculation (p. 84) for the complete details.

**3.14.13. I-deas Universal Files**

**Important**

If you intend to export data to I-deas, ensure that the mesh does not contain pyramidal elements, as these are currently not supported by I-deas.

Select I-deas Universal from the File Type drop-down list. Select the surface(s) for which you want to write data in the Surfaces list. If no surfaces are selected, the entire domain is exported. You can specify which scalars you want in the Quantities list.

You have the option of selecting loads to be included in the exported file. When the Energy Equation is enabled in the Energy Dialog Box (p. 1903), you can choose the loads based on the kind of finite element analysis you intend to undertake. By selecting Structural in the Analysis list, you can select the following Structural Loads: Force, Pressure, and Temperature. By selecting Thermal in the Analysis list, you can select the following Thermal Loads: Temperature, Heat Flux, and Heat Trans Coeff.

These loads have the following limitations:

- When the Energy Equation is disabled, only the Structural Loads options of Force and Pressure are available.
- Loads are written only on boundary walls when the entire domain is exported (that is, if no Surfaces are selected).

**Important**

For non-stationary reference zones, all the velocities are exported to I-deas Universal as velocities relative to the selected reference zone. See the informational note in Data Explorer Files (p. 75) for further details.

Click the Write... button to save the file, using the Select File dialog box. A single file is written containing coordinates, connectivity, optional loads, zone groups, velocity, and selected scalars.

You have the option of exporting data at specified intervals during a transient calculation through the Automatic Export dialog box. See Exporting Data During a Transient Calculation (p. 84) for the complete details.

**3.14.14. NASTRAN Files**

Select NASTRAN from the File Type drop-down list. Select the surface(s) for which you want to write data in the Surfaces list. If you do not select any surfaces, the entire domain is exported. You can specify which scalars you want in the Quantities list.

You have the option of selecting loads to be included in the exported file. When the Energy Equation is enabled in the Energy Dialog Box (p. 1903), you can choose the loads based on the kind of finite element analysis you intend to undertake. By selecting Structural in the Analysis list, you can select the following
Structural Loads: **Force, Pressure**, and **Temperature**. By selecting **Thermal** in the **Analysis** list, you can select the following **Thermal Loads: Temperature, Heat Flux, and Heat Trans Coeff**.

These loads have the following limitations:

- When the **Energy Equation** is disabled, only the **Structural Loads** options of **Force** and **Pressure** are available.

- Loads are written only on boundary walls when the entire domain is exported (that is, if no **Surfaces** are selected).

Click the **Write...** button to save the file, using the **Select File** dialog box. A single file (for example, file.bdf) is written containing coordinates, connectivity, optional loads, zone groups, and velocity. Pressure is written as **PLOAD4**, and heat flux is written as **QHBDYE** data. If you select wall zones in the **Surfaces** list, nodal forces are written for the walls. When data is written for the heat transfer coefficient, it is based on the wall faces rather than the nodes.

You have the option of exporting data at specified intervals during a transient calculation through the **Automatic Export** dialog box. For details, see **Exporting Data During a Transient Calculation** (p. 84).

### 3.14.15. PATRAN Files

Select **PATRAN** from the **File Type** drop-down list. Select the surface(s) for which you want to write data in the **Surfaces** list. If you do not select any surfaces, the entire domain is exported. You can specify which scalars you want in the **Quantities** list.

You have the option of selecting loads to be included in the exported file. When the **Energy Equation** is enabled in the **Energy Dialog Box** (p. 1903), you can choose the loads based on the kind of finite element analysis you intend to undertake. By selecting **Structural** in the **Analysis** list, you can select the following **Structural Loads: Force, Pressure, and Temperature**. By selecting **Thermal** in the **Analysis** list, you can select the following **Thermal Loads: Temperature, Heat Flux, and Heat Trans Coeff**.

These loads have the following limitations:

- When the **Energy Equation** is disabled, only the **Structural Loads** options of **Force** and **Pressure** are available.

- Loads are written only on boundary walls when the entire domain is exported (that is, if no **Surfaces** are selected).

Click the **Write...** button to save the file, using the **Select File** dialog box. A neutral file (for example, file.out) is written containing coordinates, connectivity, optional loads, zone groups, velocity, and selected scalars. Pressure is written as a distributed load. If wall zones are selected in the **Surfaces** list, nodal forces are written for the walls. The PATRAN result template file (for example, file.res_tmpl) is written, which lists the scalars present in the nodal result file (for example, file.rst).

You have the option of exporting data at specified intervals during a transient calculation through the **Automatic Export** dialog box. For details, see **Exporting Data During a Transient Calculation** (p. 84).

### 3.14.16. RadTherm Files

The option to export a RadTherm file type is available only when the **Energy Equation** is enabled in the **Energy Dialog Box** (p. 1903). Select **RadTherm** from the **File Type** drop-down list and select the surface(s) for which you want to write data in the **Surfaces** list. If no surfaces are selected, the entire domain
is exported. If the mesh contains polyhedral cells, ANSYS Fluent will export only boundary data. No volume data will be exported.

Select the method of writing the heat transfer coefficient (**Heat Transfer Coefficient**), which can be **Flux Based** or, if a turbulence model is enabled, **Wall Function** based.

Click the **Write...** button to save the file, using the **Select File** dialog box. A PATRAN neutral file (for example, file.neu) is written containing element velocity components (that is, the element that is just touching the wall), heat transfer coefficients, and temperatures of the wall for any selected wall surface. If the wall is one-sided, the data is written for one side of the wall. If the wall is two-sided (a wall-wall shadow pair), the values are written only for the original wall face, not for the shadow face (which is a duplicate).

You have the option of exporting data at specified intervals during a transient calculation through the **Automatic Export** dialog box. See **Exporting Data During a Transient Calculation** (p. 84) for the complete details.

### 3.14.17. Tecplot Files

Select **Tecplot** from the **File Type** drop-down list and choose the surface(s) for which you want to write data in the **Surfaces** list. If no surfaces are selected, the data is written for the entire domain. Select the variable(s) for which data is to be saved in the **Quantities** list.

Click the **Write...** button to save the file, using the **Select File** dialog box. A single file is written containing the coordinates and scalar functions in the appropriate tabular format.

**Important**

- The **utility fe2ram** can import Tecplot files only in **FEPOINT** format.

- If you intend to postprocess ANSYS Fluent data with Tecplot, you can either export data from ANSYS Fluent and import it into Tecplot, or use the Tecplot ANSYS Fluent Data Loader included with your Tecplot distribution. The data loader reads native ANSYS Fluent case and data files directly. If you are interested in this option, contact Tecplot, Inc. for assistance or visit www.tecplot.com.

You have the option of exporting data at specified intervals during a transient calculation through the **Automatic Export** dialog box. See **Exporting Data During a Transient Calculation** (p. 84) for the complete details.

### 3.15. Exporting Steady-State Particle History Data

Particle history data can be exported for steady-state solutions or for single transient particle steps by selecting the **Particle History Data...** option under the **File/Export** menu and performing the steps described in this section. For details about exporting particle history data automatically during transient simulations, see **Creating Automatic Export Definitions for Transient Particle History Data** (p. 88).

**File → Export → Particle History Data...**
Figure 3.6: The Export Particle History Data Dialog Box

1. Specify the **File Type** you want to export by selecting one of the following:
   - **CFD-Post** for the CFD-Post compatible format
   - **FieldView** for the FIELD VIEW format
   - **EnSight** for the EnSight format
   - **Geometry** for the `.ibl` format (not available when **Unsteady Particle Tracking** is enabled in the **Discrete Phase Model** dialog box)

   **Important**

   If you plan to export particle data to EnSight, you should first verify that you have already written the files associated with the EnSight Case Gold file type by using the **File/Export/Solution Data...** menu option (see **EnSight Case Gold Files** (p. 76)).

   Select the predefined injections that are the source of the particles from the **Injections** selection list. See Creating and Modifying Injections (p. 1174) for details about creating injections.

2. Select the particle variables contained in the export file by clicking the **Exported Particle Variables...** button and selecting the variables appearing in the **Reporting Variables** dialog box (Figure 24.40: The Reporting Variables Dialog Box (p. 1228)), as described in Reporting of Current Positions for Unsteady Tracking (p. 1229).

3. If you have added the **Color by** variable in the **Reporting Variables** dialog box, select an appropriate category and variable under **Quantity** for the particle data to be exported.

4. If your exported particle history file is too large to postprocess because there are too many tracks or particles written to the file, you can reduce the number of particle tracks by increasing the **Skip** value.

5. To control the exported file size, the number of points of the particle trajectories can be reduced using the **Coarsen** value. This is only valid for steady-state particle trajectories.
6. Enter the name (and folder path, if you do not want it to be written in the current folder) for the exported particle data file in the **Particle File Name** text box. Alternatively, you can specify it through the **Select File** dialog box, which is opened by clicking the **Browse...** button.

7. If you selected **EnSight** under **File Type**, you should specify the **EnSight Encas File Name**. Use the **Browse...** button to select the .encas file that was created when you exported the file with the **File/Export/Solution Data...** menu option. The selected file will be modified and renamed as a new file that contains information about all of the related particle files that are generated during the export process (including geometry, velocity, scalars, particle and particle scalar files).

   The name of the new file will be the root of the original file with .new appended to it (for example, if test.encas is selected, a file named test.new.encas will be written). It is this new file that should be read into EnSight. If you do not specify a **EnSight Encas File Name**, then you must create an appropriate .encas file manually.

8. If you selected **EnSight** under **File Type**, and you are exporting steady-state particle tracks, enter the **Number of Particle Time Steps**.

9. Click **Write** to export the particle history data. If you selected **EnSight** under **File Type**, data files will be written in both .mpg and .mscl formats.

10. Click **Close** to close the dialog box.

**3.16. Exporting Data During a Transient Calculation**

Before you run a transient flow solution, you can set up the case file so that solution data and particle history data is exported as the calculation progresses. This is accomplished by creating automatic export definitions using the **Calculation Activities Task Page** (p. 2254) (Figure 3.7: The **Calculation Activities Task Page** (p. 85)), as described in the following sections.
The names of the automatic export definitions you create are displayed in the Automatic Export selection list, along with the format in which it will be exported. You can edit or delete the definition by selecting a definition in the list and clicking the Edit... or Delete button.

For additional information, see the following sections:

3.16.1. Creating Automatic Export Definitions for Solution Data
3.16.2. Creating Automatic Export Definitions for Transient Particle History Data

3.16.1. Creating Automatic Export Definitions for Solution Data

To create an automatic export definition for solution data, begin by making sure that Transient is selected for Time in the General Task Page (p. 1888). Next, click the Create button under the Automatic Export... button.
Export selection list in the Calculation Activities task page (a drop-down list will appear). Select Solution Data Export... from the drop-down list to open the Automatic Export dialog box (Figure 3.8: The Automatic Export Dialog Box (p. 86)).

**Figure 3.8: The Automatic Export Dialog Box**

![Automatic Export Dialog Box](image)

Then perform the following steps:

1. Enter a name for the automatic export definition in the Name text box. This is the name that will be displayed in the Automatic Export selection list in the Calculation Activities task page.

2. Define the data to be exported by making selections in the relevant group boxes and selection lists: File Type, Cell Zones, Surfaces, Interior Zone Surfaces, Quantities, Analysis, Structural Loads, Thermal Loads, Location, Delimiter, Format, and Heat Transfer Coefficient. See ABAQUS Files (p. 71) – Tecplot Files (p. 82) for details about the specific options available for the various file types.

3. Set the Frequency at which the solution data will be exported during the calculation. If you enter 10 in the Frequency text box, for example, a file will be written after every 10 time steps.

4. If you selected EnSight Case Gold from the File Type drop-down list, the Separate Files for Each Time Step option allows you to specify that separate files are written at the prescribed time steps. This option
is enabled by default and is the recommended practice, as it ensures that all of the data is not lost if there is a disruption to the calculation (for example, from a network failure) before it is complete. If you choose to disable this option, all of the data for the .scll and .vel files will be combined into a single file for each.

5. If you selected **CFD-Post Compatible** from the **File Type** drop-down list, by default ANSYS Fluent will save a case (.cas) file with every .cdat file (that is, at the specified **Frequency**). You can change the criteria for when case files are saved by disabling the **Write Case File Every Time** option; then, ANSYS Fluent will save case files according to the settings specified by the following text command:

```
file  transient-export  settings  cfd-post-compatible
```

By default, the **cfd-post-compatible** text command is set to save a case file only if ANSYS Fluent detects that the mesh or case file has been modified.

Note that regardless of the settings, only a single .cst file will be written when exporting during a transient calculation.

For more information about the **CFD-Post Compatible** file type, go to **ANSYS CFD-Post-Compatible Files (p. 74)**.

6. Specify how the exported files will be named. Every file saved will begin with the characters entered in the **File Name** text box (note that a file extension is not necessary). You can specify a folder path if you do not want it written in the current folder. The **File Name** can also be specified through the **Select File** dialog box, which is opened by clicking the **Browse...** button.

Next, make a selection in the **Append File Name with** drop-down list, to specify that the **File Name** be followed by either the time step or flow time at which it was saved. Note that this selection is not available when exporting to EnSight. When **EnSight Case Gold** is selected from the **File Type** drop-down list, the time step is always appended if the **Separate Files for Each Time Step** option is enabled; otherwise, no digits are appended.

When appending the file name with the flow time, you can specify the number of decimal places that will be used by making an entry in the **Decimal Places in File Name** text box. By default, six decimal places will be used.

7. Click **OK** to save the settings for the automatic export definition.

For details about general limitations for exporting solution data and the manner in which it is exported, see **Exporting Solution Data (p. 68)**.

---

**Important**

- If the files that are exported during multiple transient simulations are to be used as a set, you should run all of the simulations on the same platform, using the same number of processors. This ensures that all of the files are compatible with each other.

- If you selected **EnSight Case Gold** from the **File Type** drop-down list, note the following:
  
  - Though it is possible for ANSYS Fluent to export a file that is greater than 2 Gbytes, such a file could not be read using EnSight when it is run on 32-bit Windows, as this exceeds EnSight's maximum file size.
– ANSYS Fluent does not support exporting data files to EnSight during a transient calculation in which a new cell zone or surface is created after the calculation has begun (as can be the case for an in-cylinder simulation, for example).

### 3.16.2. Creating Automatic Export Definitions for Transient Particle History Data

To create an automatic export definition for particle history data, begin by making sure that **Unsteady Particle Tracking** is selected in the **Discrete Phase Model** dialog box. Next, click the **Create** button under the **Automatic Export** selection list in the **Calculation Activities** task page (a drop-down list will appear). Select **Particle History Data Export...** from the drop-down list to open the **Automatic Particle History Data Export** dialog box (Figure 3.9: The Automatic Particle History Data Export Dialog Box (p. 88)).

#### Figure 3.9: The Automatic Particle History Data Export Dialog Box

![Automatic Particle History Data Export Dialog Box](image)

Then perform the following steps:

1. Enter a name for the automatic export definition in the **Name** text box. This is the name that will be displayed in the **Automatic Export** selection list in the **Calculation Activities** task page. Make sure that the chosen name is not already used for another **Automatic Export**.

2. Choose the **File Type** you want to export by selecting one of the following:
   - **CFD-Post** for the CFD-Post compatible format
   - **FieldView** for the FIELDVIEW format
• **EnSight** for the EnSight format

---

**Important**

If you plan to export particle data to EnSight, you should first set up an automatic export definition so that solution data is also exported to EnSight during this calculation (see Creating Automatic Export Definitions for Solution Data (p. 85)). As described in the steps that follow, some of the settings must correspond between the two automatic export definitions.

3. Select the predefined injections that are the source of the particles from the **Injections** selection list. See Creating and Modifying Injections (p. 1174) for details about creating injections.

4. Select the particle variables contained in the export file by clicking the **Exported Particle Variables...** button and selecting the variables appearing in the **Reporting Variables** dialog box (Figure 24.40: The Reporting Variables Dialog Box (p. 1228)), as described in Reporting of Current Positions for Unsteady Tracking (p. 1229).

5. If you have added the **Color by** variable in the **Reporting Variables** dialog box, select an appropriate category and variable under **Quantity** for the particle data to be exported.

6. Set the **Frequency** at which the particle history data will be exported during the calculation. If you enter 10 in the **Frequency** text box, for example, a file will be written after every 10 time steps for transient flow cases or 10 DPM iterations for steady flow cases.

7. If your exported particle history file is too large to postprocess because there are too many tracks or particles written to the file, you can reduce the number of particle tracks by increasing the **Skip** value.

8. If you selected **EnSight Case Gold** for the **File Type**, the **Separate Files for Each Time Step** option allows you to specify that separate files are written at the prescribed time steps. This option is enabled by default and is the recommended practice, as it ensures that all of the data is not lost if there is a disruption to the calculation (for example, from a network failure) before it is complete. If you choose to disable this option, all of the data for the .mscl and .mpg files will be combined into a single file for each.

---

**Important**

The setting for the **Separate Files for Each Time Step** option should be the same (that is, enabled or disabled) as that of the automatic export definition you set up to export solution data to EnSight during this calculation. For details, see Creating Automatic Export Definitions for Solution Data (p. 85).

9. Enter the name (and folder path, if you do not want it to be written in the current folder) for the exported particle data file in the **Particle File Name** text box. Alternatively, you can specify it through the **Select File** dialog box, which is opened by clicking the **Browse...** button. Make sure the file name is different from other existing automatic export definitions to avoid overwriting data.

10. If you selected **EnSight** under **File Type**, you should specify the **EnSight Encas File Name**. Enter the same name (and folder path, if necessary) that you entered in the **File Name** text box when you set up the automatic export definition for exporting solution data to EnSight during this calculation. (For details, see Creating Automatic Export Definitions for Solution Data (p. 85)). The .encas file created during the solution data export will be modified and renamed as a new file that contains information about all of
the related particle files that are generated after every time step during the export process (including geometry, velocity, scalars, particle and particle scalar files). The name of the new file will be the root of the original .encas file with .new appended to it (for example, if the solution data export creates test.encas, a file named test.new.encas will be written for the particle data export). It is this new file that should be read into EnSight.

**Important**

If you do not specify an **EnSight Encas File Name**, you will have to manually create an appropriate .encas file.

11. Click **OK** to save the settings for the automatic export definition.

The particle data will be exported as it is generated during the transient calculation. If you selected **EnSight** under **File Type**, data files will be written in both .mpg and .mscl formats.

### 3.17. Exporting to ANSYS CFD-Post

You can use the **Export to CFD-Post** dialog box ([Figure 3.10: The Export to CFD-Post Dialog Box (p. 91)](https://www.ansys.com/products/cfd/post-processing)) to export the results from all of the cell zones to files that are compatible with ANSYS CFD-Post.

**File → Export to CFD-Post...**
Select the variables for which you want data saved from the **Select Quantities** selection list. When selecting the variables, be sure to include any variable that was used to create an isosurface or clipped surface (as described in **Isosurfaces** (p. 1595) and **Clipping Surfaces** (p. 1597), respectively); otherwise, the surface will not be created properly if you try to read the exported state file in CFD-Post.

Specify the format of the `.cdat` file by selecting either **Binary** or **ASCII** from the **Format** list. The advantage of the binary format is that it takes less time to load the exported data into ANSYS CFD-Post and requires less storage space. Note that the format for the `.cst` will always be ASCII.

By default, Fluent will write a case file (that is, `.cas`) along with the **CFD-Post Compatible** files. If you do not want such a case file for any reason (for example, to improve I/O performance or save disk space), disable the **Write Case File** option. Disabling this option is only recommended if you are performing multiple export operations for a case file that is not changing.

By default, the **Open CFD-Post** option is enabled so that the following actions will occur after the files are exported:

1. A CFD-Post session opens automatically.
2. The case and `.cdat` files are loaded in CFD-Post.
3. CFD-Post displays the results.
If you disable the **Open CFD-Post** option, you can open CFD-Post manually and use the **Load Results** item in the **File** drop-down menu to load the results files. For more information about this feature in CFD-Post, see the separate ANSYS CFD-Post manual.

Click the **Write...** button to save the files, using the **Select File** dialog box. A `.cdat` file is written, containing the specified variable data for the specified cell zones and all of the boundary zones. A state file (that is, `.cst`) is also written, which contains the following surfaces that you created in Fluent for postprocessing: point surfaces, line surfaces, plane surfaces, isosurfaces, and clipped surfaces (see *Creating Surfaces for Displaying and Reporting Data (p. 1579)*).

### Important

When you read the `.cdat` file into ANSYS CFD-Post, the application will attempt to read in the case file that produced the data by looking in the folder for a `.cas` file with the same prefix. If the case file is not in that folder (e.g., if you disabled the **Write Case File** option when exporting), ANSYS CFD-Post will prompt you to specify the appropriate case file.

### Important

Before loading the `.cst` file into ANSYS CFD-Post, make sure that the `.cas` and `.cdat` files are already loaded for the session.

You have the option of exporting data at specified intervals during a transient calculation through the **Automatic Export** dialog box. See *Exporting Data During a Transient Calculation (p. 84)* for the complete details.

### 3.18. Managing Solution Files

You can manage your solution files effectively and efficiently using the **Solution Files** dialog box. Here, you can select previously saved files created using the **Autosave** dialog box and read or delete them.

**File → Solution Files...**

**Figure 3.11: The Solution Files Dialog Box**

![Solution Files dialog box](image)
The Solution Files dialog box (Figure 3.11: The Solution Files Dialog Box (p. 92)) lists all of the solution files that have been automatically saved. They are listed by iteration number or time step/flow time. For the file that is currently read in, the status of current will appear in the Solution Files at list. You can make any of the files in the list current by clicking the Read button. Note that if more than one file is selected, the Read button is disabled. When an earlier solution is made current, the solution files that were generated for a later iteration/time step will be removed from this list when the calculation continues.

You can delete solution files by selecting an entry in the list and clicking Delete. Note that a currently loaded solution file cannot be deleted, however multiple (non-current) files can be selected and deleted. If multiple files are selected and one of those files is a currently loaded solution file, clicking Delete will result in the current solution file being skipped.

You can click the File Names... button to obtain information about the solution files and the path of the associated files.

The Solution Files dialog box is particularly useful for reading in files that were saved during the autosave session, since case and data files may not necessarily have the same file name.

### 3.19. Mesh-to-Mesh Solution Interpolation

ANSYS Fluent can interpolate solution data for a given geometry from one mesh to another, allowing you to compute a solution using one mesh (for example, hexahedral) and then change to another mesh (for example, hybrid) and continue the calculation using the first solution as a starting point.

---

**Important**

ANSYS Fluent does zeroth-order interpolation for interpolating the solution data from one mesh to another.

---

For additional information, see the following sections:

- 3.19.1. Performing Mesh-to-Mesh Solution Interpolation
- 3.19.2. Format of the Interpolation File

#### 3.19.1. Performing Mesh-to-Mesh Solution Interpolation

The procedure for mesh-to-mesh solution interpolation is as follows:

1. Set up the model and calculate a solution on the initial mesh.

2. Write an interpolation file for the solution data to be interpolated onto the new mesh, using the Interpolate Data dialog box (Figure 3.12: The Interpolate Data Dialog Box (p. 94)).

   **File → Interpolate...**
a. Under **Options**, select **Write Data**.

b. In the **Cell Zones** selection list, select the cell zones for which you want to save data to be interpolated.

   **Note**

   If your case includes both fluid and solid zones, write the data for the fluid zones and the data for the solid zones to separate files.

c. Select the variable(s) for which you want to interpolate data in the **Fields** selection list. All ANSYS Fluent solution variables are available for interpolation.

d. Select the **Binary File** check box if you want a binary interpolation file to be generated.

   **Note**

   Writing a binary interpolation file is significantly faster and requires less memory than writing a text file.

e. Click **Write...** and specify the interpolation file name in the resulting **Select File** dialog box. The file format is described in **Format of the Interpolation File** (p. 95).

3. Set up a new case.

   a. Read in the new mesh, using the appropriate menu item in the **File/Read/** or **File/Import/** menu.
b. Define the appropriate models.

**Important**

Enable all of the models that were enabled in the original case. For example, if the energy equation was enabled in the original case and you forget to enable it in the new case, the temperature data in the interpolation file will not be interpolated.

c. Define the boundary conditions, material properties, etc.

**Important**

An alternative way to set up the new case is to save the boundary conditions from the original model using the `write-settings` text command, and then read in those boundary conditions with the new mesh using the `read-settings` text command. See *Reading and Writing Boundary Conditions (p. 56)* for further details.

4. Read in the data to be interpolated.

**File → Interpolate...**

a. Under **Options**, select **Read and Interpolate**.

b. In the **Cell Zones** list, select the cell zones for which you want to read and interpolate data.

If the solution has not been initialized, computed, or read, all zones in the **Cell Zones** list are selected by default, to ensure that no zone remains without data after the interpolation. If all zones already have data (from initialization or a previously computed or read solution), select a subset of the **Cell Zones** to read and interpolate data onto a specific zone (or zones).

c. Click the **Read...** button and specify the interpolation file name in the resulting **Select File** dialog box.

**Important**

If your case includes both fluid and solid zones, the two sets of data are saved to separate files. Hence perform these steps twice, once to interpolate the data for the fluid zones and once to interpolate the data for the solid zones.

5. Reduce the under-relaxation factors and calculate on the new mesh for a few iterations to avoid sudden changes due to any imbalance of fluxes after interpolation. Then increase the under-relaxation factors and compute a solution on the new mesh.

**3.19.2. Format of the Interpolation File**

An example of an interpolation file is shown below:

```
3
2
34800
```
The format of the interpolation file is as follows:

• The first line is the interpolation file version. It is 2 for files generated using ANSYS Fluent 12.0 through 14.0, 3 for text files generated using ANSYS Fluent 14.5, 4 for binary files generated using single precision ANSYS Fluent 14.5, and 5 for files generated using double precision ANSYS Fluent 14.5.

• The second line is the dimension (2 or 3).

• The third line is the total number of points.

• The fourth line is the total number of fields (temperature, pressure, etc.) included.

• Starting at the fifth line is a list of field names. To see a complete list of the field names used by ANSYS Fluent, enter the display/contour text command and view the available choices by pressing Enter at the contours of> prompt. The list depends on the models turned on.

• After the field names is a section for each list of \( x, y, \) and (in 3D) \( z \) coordinates for all the data points.

• At the end is a section for each list of the field values at all the points in the same order as their names. The number of coordinate and field points should match the number given in line 3.

• For version 3 interpolation files, the sections are bounded by "(" and ")".

• For version 4 and 5 interpolation files, the sections are bounded by "(" and "\nEnd of Binary Section 0)".

• The delimiters help skip a section if the associated model is not enabled. With version 2 interpolation files (where the delimiters do not exist), sections may not be skipped properly if the size of the field cannot be determined without enabling the associated model. This may result in incorrect interpolation of the subsequent field variables.

---

**Important**

An interpolation file written with ANSYS Fluent 14.5 and above is not readable in prior versions of ANSYS Fluent.

### 3.20. Mapping Data for Fluid-Structure Interaction (FSI) Applications

ANSYS Fluent allows you to map variables (for example, temperature, pressure) from the cell or face zones of an ANSYS Fluent simulation onto locations associated with a finite element analysis (FEA) mesh. The results are written to a file for inclusion into an FEA simulation. During this process, both the original and the new mesh can be viewed simultaneously. ANSYS Fluent maps the data using zeroth-order interpolation, and can write the output file in a variety of formats.

This capability is useful when solving fluid-structure interaction (FSI) problems, and allows you to perform further analysis on the solid portion of your model using FEA software. Mapping the data may be
preferable to simply exporting the ANSYS Fluent data file (as described in Exporting Solution Data (p. 68)), since the meshes used in CFD analysis are typically finer than those used in finite element analysis.

For additional information, see the following sections:
3.20.1. FEA File Formats
3.20.2. Using the FSI Mapping Dialog Boxes

3.20.1. FEA File Formats

The FEA software types that are compatible with ANSYS Fluent’s FSI mapping capability include ABAQUS, I-deas, ANSYS, NASTRAN, and PATRAN. For details about the kinds of files that can be read or written during this process, see Table 3.4: FEA File Extensions for FSI Mapping (p. 97).

Table 3.4: FEA File Extensions for FSI Mapping

<table>

<td>.out</td>
</tr>
</tbody>
</table>

3.20.2. Using the FSI Mapping Dialog Boxes

To begin the process of mapping ANSYS Fluent data, you must first create a mesh file that can be used as the input file in the steps that follow. The resolution of the mesh should be appropriate for your eventual finite element analysis. You are free to use the method and preprocessor of your choice in the creation of this file, but the end result must correspond to one of the entries in the Input File column of Table 3.4: FEA File Extensions for FSI Mapping (p. 97).

When creating the input file, note the following:

- While the input file may be scaled when it is read into ANSYS Fluent, the volumes or surfaces on which the data is to be mapped must otherwise be spatially coincident with their counterparts in the ANSYS Fluent simulation.

- ANSYS Fluent can map volume and surface data only for 3D cases; data mapping is not supported for 2D cases since data mapping for edges is not supported.

- The input file can be only a portion of the overall FEA model (that is, you can exclude the parts of the model on which you are not mapping ANSYS Fluent data). When this is the case, note that the numbering of the nodes and elements in the input file must match the numbering of the nodes and elements in the complete file you will use for your finite element analysis.

Next, read a case file in ANSYS Fluent and make sure data is available for mapping, either by running the calculation or by reading a data file.

Finally, perform the following steps to generate an output file in which the ANSYS Fluent data has been mapped to the mesh of the input file:

1. Open the ANSYS Fluent dialog box that is appropriate for the zones from which the data is to be taken. If the data you are mapping is from a volume (for example, the cell zone of a solid region), open the...
**Volume FSI Mapping** dialog box using the **File/FSI Mapping/Volume** menu item (*Figure 3.13: The Volume FSI Mapping Dialog Box for Cell Zone Data (p. 98)*). If instead the data is from a surface (for example, a face boundary zone), open the **Surface FSI Mapping** dialog box using the **File/FSI Mapping/Surface** menu item (*Figure 3.14: The Surface FSI Mapping Dialog Box for Face Zone Data (p. 99)*).

**File → FSI Mapping → Volume...**

or

**File → FSI Mapping → Surface...**

*Figure 3.13: The Volume FSI Mapping Dialog Box for Cell Zone Data*
2. Specify the parameters of the input file and read it into ANSYS Fluent.

   a. Select the format of the input file from the **Type** list in the **Input File** group box, based on the FEA software with which it is associated. The choices include:

      - ABAQUS
      - I-deas
      - Mechanical APDL
      - NASTRAN
      - PATRAN

      For a list of the file extensions associated with these types, see the Input File column of *Table 3.4: FEA File Extensions for FSI Mapping (p. 97).*

   b. Enter the name and extension (along with the folder path, if it is not in the current folder) of the input file in the **FEA File** text-entry box. Alternatively, you can specify it through the **Select File** dialog box, which is opened by clicking the **Browse...** button.

   c. Specify the length units that were used in the creation of the input file by making a selection from the **Length Units** drop-down menu. This ensures that the input file is scaled appropriately relative to the ANSYS Fluent file.
d. Click the **Read** button to read the input file into memory.

**Important**

Note that the input file will only be held in memory until the output file is written, or until the FSI mapping dialog box is closed.

---

3. Display the meshes so that you can visually verify that the input file is properly scaled and aligned with the ANSYS Fluent mesh file.

a. Make sure that the **FEA Mesh** and **Fluent - Mesh** options are selected in the **Display Options** group box. Note that you can disable either of these options if you want to examine one of the meshes independently.

b. Click the **Display** button to display the meshes in the graphics window.

**Important**

For the ANSYS Fluent mesh, only the zones selected in the **Fluent Zones** group box will be displayed—in this case, the default selections. If the default zones are not appropriate, you should redisplay the meshes after you make your zone selections in a later step.

---

4. Specify the type of data variables to be mapped.

a. Select either **Structural** or **Thermal** in the **Analysis** group box. Your selection should reflect the kind of further analysis you intend to pursue, and will determine what variables are available for mapping.

b. Enable the variables you want to map in the **Structural Loads** or **Thermal Loads** group box. When mapping volume data, you can enable only **Temperature**. When mapping surface data, you can enable **Force**, **Pressure**, and **Temperature** for structural analysis, or **Temperature**, **Heat Flux**, and **Heat Trans Coeff** for thermal analysis.

**Important**

Note that the **Energy Equation** must be enabled in the **Energy** dialog box if you want to map temperature for a structural analysis or any variable for a thermal analysis.

---

5. Select the zones that contain the data to be mapped in the **Fluent Zones** group box. You can select individual zones in the **Cell Zones** or **Face Zones** selection lists, or select all zones of a particular type in the **Zone Type** selection list. If you modify the default selections, you should display the meshes again, as described previously.

**Important**

- Note that all wall zones in the **Face Zones** selection list are selected by default in the **Surface FSI Mapping** dialog box, and this includes the shadow walls created for two-sided walls.
  
  If your ANSYS Fluent file contains a wall/shadow pair (for example, separating a solid zone...
from a fluid zone), you should make sure that only the correct wall or shadow of the pair is selected.

• Inlet zones do not have heat transfer coefficient data, and so any attempts to map this combination will be ignored.

6. Specify the parameters of the output file and write it.

a. Select the format of the output file from the **Type** list in the **Output File** group box, based on the software with which you plan to perform your finite element analysis. The choices in this list are the same as those for the input file type. Note that you can select an output file type that is different from the input file type.

For details about the file extensions associated with the various types of output files, see the **Output File** column of Table 3.4: FEA File Extensions for FSI Mapping (p. 97).

b. Enter the name (with the folder path, if appropriate) of the output file in the **File Name** text-entry box. Alternatively, you can specify it through the **Select File** dialog box, which is opened by clicking the **Browse...** button.

c. To include additional FEA information like node/element information in the exported output file, enable **Include FEA Mesh**. By default, this option is disabled and therefore, only the selected boundary condition values are exported.

d. When mapping temperature for a structural analysis or any variable for a thermal analysis, make a selection in the **Temperature Units** drop-down menu. Table 3.5: Units Associated with the Temperature Units Drop-Down List Selections (p. 101) shows the units for the mapped variables, depending on the **Temperature Units** selection.

<table>
<thead>
<tr>
<th>Temperature Units Selection</th>
<th>Temperature</th>
<th>Heat Flux</th>
<th>Heat Transfer Coefficient</th>
</tr>
</thead>
<tbody>
<tr>
<td>K</td>
<td>K</td>
<td>W/m²</td>
<td>W/m²-K</td>
</tr>
<tr>
<td>°C</td>
<td>°C</td>
<td>W/m²</td>
<td>W/m²-°C</td>
</tr>
<tr>
<td>°F</td>
<td>°F</td>
<td>BTU/ft²-hr</td>
<td>BTU/ft²-hr-°F</td>
</tr>
</tbody>
</table>

e. When mapping the heat transfer coefficient for a thermal analysis, make a selection in the **HTC Type** drop-down menu to determine how the heat transfer coefficient $h_{eff}$ is calculated.

**ref-temp**

calculates $h_{eff}$ using Equation 33.42 (p. 1819), where $T_{ref}$ is the reference temperature defined in the Reference Values Task Page (p. 2202). Note that this option has the same definition as the field variable **Surface Heat Transfer Coef.**, as described in Alphabetical Listing of Field Variables and Their Definitions (p. 1787).
cell-temp
calculates \( h_{eff} \) using the general form of Equation 33.42 (p. 1819), but defines \( T_{ref} \) as the temperature of the cell adjacent to the face.

wall-func-htc
calculates \( h_{eff} \) using Equation 33.54 (p. 1825). Note that this option has the same definition as the field variable Wall Func. Heat Tran. Coef., as described in Alphabetical Listing of Field Variables and Their Definitions (p. 1787).

f. Click **Write** to write an output file in which the ANSYS Fluent data has been mapped to the mesh of the input file.

The input file will be released from memory when the output file is written.

### 3.21. Saving Picture Files

Graphic window displays can be saved in various formats (including TIFF and PostScript). There can be slight differences between pictures and the displayed graphics windows, since pictures are generated using the internal software renderer, while the graphics windows may utilize specialized graphics hardware for optimum performance.

Many systems provide a utility to “dump” the contents of a graphics window into a raster file. This is generally the fastest method of generating a picture (since the scene is already rendered in the graphics window), and guarantees that the picture is identical to the window.

For additional information, see the following sections:

3.21.1. Using the Save Picture Dialog Box
3.21.2. Picture Options for PostScript Files

#### 3.21.1. Using the Save Picture Dialog Box

To set picture parameters and save picture files, use the Save Picture Dialog Box (p. 2309) (Figure 3.15: The Save Picture Dialog Box (p. 102)).

**File → Save Picture...**

**Figure 3.15: The Save Picture Dialog Box**

[Image of the Save Picture Dialog Box]
For your convenience, this dialog box may also be opened using the **Save Picture** button ( ) in the standard toolbar.

The procedure for saving a picture file is as follows:

1. Choose the picture file **Format**.
2. Set the **Coloring**.
3. Specify the **File Type**, if applicable.
4. Define the **Resolution**, if applicable.
5. Set the appropriate **Options**.
6. If you are generating a window dump, specify the **Window Dump Command**.
7. (optional) Preview the result by clicking **Preview**.
8. Click the **Save...** button and enter the file name in the resulting **Select File** dialog box. See **Automatic Numbering of Files (p. 45)** for information on special features related to file name specification.

If you are not ready to save a picture but want to save the current picture settings, click the **Apply** button instead of the **Save...** button. The applied settings become the defaults for subsequent pictures.

### 3.21.1.1. Choosing the Picture File Format

To choose the picture file format, select one of the following items in the **Format** list:

**EPS**
(Encapsulated PostScript) output is the same as PostScript output, with the addition of Adobe Document Structuring Conventions (v2) statements. Currently, no preview bitmap is included in EPS output. Often, programs that import EPS files use the preview bitmap to display on-screen, although the actual vector PostScript information is used for printing (on a PostScript device). You can save EPS files in raster or vector format.

**JPEG**
is a common raster file format.

**PPM**
output is a common raster file format.

**PostScript**
is a common vector file format. You can also choose to save a PostScript file in raster format.

**TIFF**
is a common raster file format.

**PNG**
is a common raster file format.
VRML

is a graphics interchange format that allows export of 3D geometrical entities that you can display in the ANSYS Fluent graphics window. This format can commonly be used by VR systems and the 3D geometry can be viewed and manipulated in a web-browser graphics window.

---

**Important**

Non-geometric entities such as text, titles, color bars, and orientation axis are not exported. In addition, most display or visibility characteristics set in ANSYS Fluent, such as lighting, shading method, transparency, face and edge visibility, outer face culling, and hidden line removal, are not explicitly exported but are controlled by the software used to view the VRML file.

---

**Window Dump**

(Windows systems only) selects a window dump operation for generating the picture. With this format, you must specify the appropriate **Window Dump Command**.

---

### 3.21.1.2. Specifying the Color Mode

For all formats except VRML and the window dump, specify the type of **Coloring** you want to use for the picture file.

- Select **Color** for a color-scale copy.
- Select **Gray Scale** for a gray-scale copy.
- Select **Monochrome** for a black-and-white copy.

Most monochrome PostScript devices render **Color** images in shades of gray, but to ensure that the color ramp is rendered as a linearly-increasing gray ramp, you should select **Gray Scale**.

---

### 3.21.1.3. Choosing the File Type

When you save an EPS (Encapsulated PostScript) or PostScript file, choose one of the following under **File Type**:

- A **Raster** file defines the color of each individual pixel in the image. Raster files have a fixed resolution. The supported raster formats are EPS, JPEG, PPM, PostScript, TIFF, and PNG.

- A **Vector** file defines the graphics image as a combination of geometric primitives like lines, polygons, and text. Vector files are usually scalable to any resolution. The supported vector formats include EPS, PostScript, and VRML.

---

**Important**

For the quickest print time, you can save vector files for simple 2D displays and raster files for complicated scenes.

---

### 3.21.1.4. Defining the Resolution

For raster picture files (that is, JPEG, PPM, TIFF, and PNG), you can control the resolution of the picture image by specifying the size (in pixels). Set the desired **Width** and **Height** under **Resolution**. If the
Width and Height are both zero, the picture is generated at the same resolution as the active graphics window. To check the size of the active window in pixels, click Info in the Display Options dialog box.

For EPS and PostScript files, specify the resolution in dots per inch (DPI) instead of setting the width and height.

3.21.1.5. Picture Options

For all picture formats except VRML and the window dump, you can control two additional settings under Options:

- Specify the orientation of the picture using the Landscape Orientation button. If this option is turned on, the picture is made in landscape mode; otherwise, it is made in portrait mode.

- Control the foreground/background color using the White Background option. If this option is enabled, the picture is saved with a white background, and (if you are using the classic color scheme for the graphics window) the foreground color is changed to black.

3.21.2. Picture Options for PostScript Files

ANSYS Fluent provides options that allow you to save PostScript files that can be printed more quickly. The following options are found in the display/set/picture/driver/post-format text menu:

- fast-raster enables a raster file that may be larger than the standard raster file, but will print much more quickly.

- raster enables the standard raster file.

- rle-raster enables a run-length encoded raster file that is about the same size as the standard raster file, but will print slightly more quickly. This is the default file type.

- vector enables the standard vector file.

3.21.2.1. Window Dumps (Linux Systems Only)

If you select the Window Dump format, the program uses the specified Window Dump Command to save the picture file. For example, if you want to use xwd to capture a window, set the Window Dump Command to

```
xwd -id %w >
```

When the dump occurs, ANSYS Fluent automatically interprets %w to be the ID number of the active window.

When you click the Save... button, the Select File dialog box appears. Enter the file name for the output from the window dump (for example, myfile.xwd).

If you are planning to make an animation, save the window dumps into numbered files, using the %n variable. To do this, use the Window Dump Command (xwd -id %w), but for the file name in the Select File dialog box enter myfile%n.xwd. Each time a new window dump is created, the value of %n increases by one. So there is no need to tack numbers onto the picture file names manually.
To use the ImageMagick animate program, saving the files in MIFF format (the native ImageMagick format) is more efficient. In such cases, use the ImageMagick tool import. Set the default Window Dump Command enter

`import -window %w`

Click Save... to invoke the Select File dialog box. Specify the output format to be MIFF by using the .miff suffix at the end of file name.

The window dump feature is both, system and graphics-driver specific. Thus the commands available for dumping windows depends on the particular configuration.

The window dump captures the window exactly as it is displayed, including resolution, colors, transparency, etc. For this reason, all of the inputs that control these characteristics are disabled in the Save Picture dialog box when you enable the Window Dump format. If you are using an 8-bit graphics display, use one of the built-in raster drivers (for example, TIFF) to generate higher-quality 24-bit color output rather than dumping the 8-bit window.

### 3.21.2.2. Previewing the Picture Image

Before saving a picture file, you have the option of previewing what the saved image will look like. Click Preview to open a new window that will display the graphics using the current settings. This allows you to investigate the effects of different options interactively before saving the final, approved picture.

### 3.22. Setting Data File Quantities

By default, the information saved in a data file includes a standard set of quantities that were computed during the calculation. These quantities are specifically suitable for postprocessing and restarting solutions in ANSYS Fluent. If, however, you plan to postprocess the data file in an application other than ANSYS Fluent (such as ANSYS CFD-Post) you may want to include additional quantities that are derived from the standard quantities.

Note that some standard quantities are also listed as additional quantities. If using ANSYS CFD-Post, where a standard quantity has a corresponding entry in the additional quantity list, the latter should be selected. This is because ANSYS CFD-Post requires that some standard quantities be derived into a specific form.

---

**Note**

Not all standard quantities will be available in CFD-Post for post processing. An example of such a quantity is the Mach number.

The procedure for generating a data file with additional quantities is as follows:

1. Set up the case file for your simulation.
2. Initialize the solution using the Solution Initialization Task Page (p. 2249).
3. Specify the quantities to be written in the data file, using the Data File Quantities dialog box (Figure 3.16: The Data File Quantities Dialog Box (p. 107)).

File → Data File Quantities...
Figure 3.16: The Data File Quantities Dialog Box

![Data File Quantities Dialog Box](image)

Many quantities are available for postprocessing in external applications through the standard data file. To include additional quantities in the data file for postprocessing in external applications, select them below.

**Standard Quantities**
- Mass Flux
- Mass Flux M1
- Body Force
- Wall Velocity
- Original Wall Velocity
- Wall Shear
- Temperature
- Inner Wall Temperature
- Boundary Heat Flux
- Boundary Rad Heat Flux
- Enthalpy
- Energy M1
- Turbulent Kinetic Energy
- Turbulent Kinetic Energy M1
- Specific Dissipation Rate
- Specific Dissipation Rate M1
- Density
- Density T-1
- Laminar Viscosity
- Turbulent Viscosity
- 2nd Grad Bc Source
- Distance From Wall

**Additional Quantities**
- Static Pressure
- Pressure Coefficient
- Dynamic Pressure
- Absolute Pressure
- Total Pressure
- Relative Total Pressure
- Density
- Density All
- Velocity Magnitude
- X Velocity
- Y Velocity
- Stream Function
- Radial Velocity
- Tangential Velocity
- Mach Number
- Relative Velocity Magnitude
- Relative X Velocity
- Relative Y Velocity
- Relative Tangential Velocity
- Relative Mach Number
- Mesh X-Velocity
- Mesh Y-Velocity

4. Save the case file. Note that the data file quantities you specified in the previous step will be saved as part of the case file.

5. Run the calculation and save the data file. This can be done as separate steps, or as one step if you have selected the automatic saving of data files via the Calculation Activities Task Page (p. 2254).

The Data File Quantities dialog box can also be opened by clicking the Data File Quantities... button in the Autosave Case/Data dialog box.

### 3.23. The .fluent File

When starting up, ANSYS Fluent looks in your home folder for an optional file called .fluent. If it finds the file, it loads it with the Scheme load function. This file can contain Scheme functions that customize the code's operation.

The .fluent file can also contain TUI commands that are executed via the Scheme function ti-menu-load-string. For example, if the .fluent file contains...
then ANSYS Fluent will read in the case file \texttt{test.cas}. For more details about the function \texttt{ti-menu-load-string}, see \textit{Text Menu Input from Character Strings (p. 37)}.

\textbf{Important}

Another optional file, \texttt{.tgrid}, if present, is also loaded at start up. This file may contain Scheme functions that customize the operation of the code in meshing mode. When both the \texttt{.fluent} and \texttt{.tgrid} files are present, the \texttt{.tgrid} file will be loaded first, followed by the \texttt{.fluent} file, when the solution mode is launched. Hence, the functions in the \texttt{.fluent} file will take precedence over those in the \texttt{.tgrid} file for the solution mode.

The \texttt{.fluent} file is not loaded automatically when switching to solution mode from meshing mode. You will need to load the file separately using the Scheme load function, if needed.
Chapter 4: Unit Systems

This chapter describes the units used in ANSYS Fluent and how you can control them. Information is organized into the following sections:

4.1. Restrictions on Units
4.2. Units in Mesh Files
4.3. Built-In Unit Systems in ANSYS Fluent
4.4. Customizing Units

ANSYS Fluent enables you to work in any unit system, including inconsistent units. Thus, for example, you may work in British units with heat input in Watts or you may work in SI units with length defined in inches. This is accomplished by providing ANSYS Fluent with a correct set of conversion factors between the units you want to use and the standard SI unit system that is used internally by the solver. ANSYS Fluent uses these conversion factors for input and output, internally storing all parameters and performing all calculations in SI units. Both solvers always prompt you for the units required for all dimensional inputs.

Units can be altered part-way through a problem setup and/or after you have completed your calculation. If you have input some parameters in SI units and then you switch to British, all of your previous inputs (and the default prompts) are converted to the new unit system. If you have completed a simulation in SI units but you would like to report the results in any other units, you can alter the unit system and ANSYS Fluent will convert all of the problem data to the new unit system when results are displayed. As noted above, all problem inputs and results are stored in SI units internally. This means that the parameters stored in the case and data files are in SI units. ANSYS Fluent simply converts these values to your unit system at the interface level.

4.1. Restrictions on Units

It is important to note that the units for some inputs in ANSYS Fluent are different from the units used for the rest of the problem setup.

• You must always define the following in SI units, regardless of the unit system you are using:
  – Boundary profiles (see Profiles (p. 377))
  – Source terms (see Defining Mass, Momentum, Energy, and Other Sources (p. 251))
  – Custom field functions (see Custom Field Functions (p. 1826))
  – Data in externally-created XY plot files (see XY Plots of File Data (p. 1701))
  – User-defined functions (See the UDF Manual for details about user-defined functions.)

• If you define a material property by specifying a temperature-dependent polynomial or piecewise-polynomial function, remember that temperature in the function is always in units of Kelvin or Rankine. If you are using Celsius or Kelvin as your temperature unit, then polynomial coefficient values must be entered in terms of Kelvin; if you are using Fahrenheit or Rankine as the temperature unit, values must be entered...
in terms of Rankine. See Defining Properties Using Temperature-Dependent Functions (p. 412) for information about temperature-dependent material properties.

4.2. Units in Mesh Files

Some mesh generators allow you to define a set of units for the mesh dimensions. However, when you read the mesh into ANSYS Fluent, it is always assumed that the unit of length is meters. If this is not true, you must scale the mesh, as described in Scaling the Mesh (p. 196).

4.3. Built-In Unit Systems in ANSYS Fluent

ANSYS Fluent provides four built-in unit systems: British, SI, CGS, and "default", all of which can be selected in the Set Units dialog box (Figure 4.1: The Set Units Dialog Box (p. 110)), using the buttons under the Set All to heading. To display the Set Units dialog box, select General in the navigation pane and click Units... in the task page.

![General](image)

To choose the English Engineering standard for all units, click the british button; to select the International System of units (SI) standard for all units, click the si button; to choose the CGS (centimeter-gram-second) standard for all units, click the cgs button; and to return to the "default" system, click the default button. The default system of units is similar to the SI system, but uses degrees instead of radians for angles. Clicking on one of the buttons under Set All to will immediately change the unit system. You can then close the dialog box if you are not interested in customizing any units.

Changing the unit system in the Set Units dialog box causes all future inputs that have units to be based on the newly selected unit system.

4.4. Customizing Units

If you would like a mixed unit system, or any unit system different from the four supplied by ANSYS Fluent (and described in Built-In Unit Systems in ANSYS Fluent (p. 110)), you can use the Set Units dialog box (Figure 4.1: The Set Units Dialog Box (p. 110)) to select an available unit or specify your own unit name and conversion factor for each quantity.
For additional information, see the following sections:

4.4.1. Listing Current Units
4.4.2. Changing the Units for a Quantity
4.4.3. Defining a New Unit

4.4.1. Listing Current Units

Before customizing units for one or more quantities, you may want to list the current units. You can do this by clicking the List button at the bottom of the Set Units dialog box. ANSYS Fluent will print out a list (in the text window) containing all quantities and their current units, conversion factors, and offsets.

4.4.2. Changing the Units for a Quantity

ANSYS Fluent will enable you to modify the units for individual quantities. This is useful for problems in which you want to use one of the built-in unit systems, but you want to change the units for one quantity (or for a few). For example, you may want to use SI units for your problem, but the dimensions of the geometry are given in inches. You can select the SI unit system, and then change the unit of length from meters to inches.

To change the units for a particular quantity, you will follow these two steps:

1. Select the quantity in the Quantities list (they are arranged in alphabetical order).
2. Choose a new unit from those that are available in the Units list.

For the example cited above, you would choose length in the Quantities list, and then select in in the Units list. The Factor will automatically be updated to show 0.0254 meters/inch. (See Figure 4.1: The Set Units Dialog Box (p. 110).) If there was a non-zero offset for the new unit, the Offset field would also be updated. For example, if you were using SI units but wanted to define temperature in Celsius instead of Kelvin, you would select temperature in the Quantities list and c in the Units list. The Factor would change to 1, and the Offset would change to 273.15. Once you have selected the quantity and the new unit, no further action is needed, unless you want to change the units for another quantity by following the same procedure.

4.4.3. Defining a New Unit

To create a new unit to be used for a particular quantity, you will follow the procedure below:

1. In the Set Units dialog box, select the quantity in the Quantities list.
2. Click the New... button and the Define Unit dialog box (Figure 4.2: The Define Unit Dialog Box (p. 112)) will open. In this dialog box, the selected quantity will be shown in the Quantity field.
3. Enter the name of your new unit in the **Unit** field, the conversion factor in the **Factor** field, and the offset in the **Offset** field.

4. Click **OK** in the **Define Unit** dialog box, and the new unit will appear in the **Set Units** dialog box.

   For example, if you want to use hours as the unit of time, select **time** in the **Quantities** list in the **Set Units** dialog box and click the **New...** button. In the resulting **Define Unit** dialog box, enter **hr** for the **Unit** and **3600** for the **Factor**, as in Figure 4.2: The Define Unit Dialog Box (p. 112). Then click **OK**. The new unit hr will appear in the **Units** list in the **Set Units** dialog box, and it will be selected.

### 4.4.3.1. Determining the Conversion Factor

The conversion factor you specify (**Factor** in the **Define Unit** dialog box) tells ANSYS Fluent the number to multiply by to obtain the SI unit value from your customized unit value. Thus the conversion factor should have the form SI units/custom units. For example, if you want the unit of length to be inches, you should input a conversion factor of 0.0254 meters/inch. If you want the unit of velocity to be feet/min, you can determine the conversion factor by using the following equation:

\[
\frac{\text{ft}}{\text{min}} \times \frac{0.3048 \text{m}}{\text{ft}} \times \frac{\text{min}}{60 \text{s}} = \frac{\text{m}}{\text{s}}
\]  

(4.1)

You should input a conversion factor of 0.0051, which is equal to 0.3048/60.
Chapter 5: Reading and Manipulating Meshes

ANSYS Fluent can import different types of meshes from various sources. You can modify the mesh by translating or scaling node coordinates, partitioning the domain for parallel processing, reordering the cells in the domain to decrease bandwidth, and merging or separating zones. You can convert all 3D meshes to polyhedral cells, except for pure hex meshes. Hexahedral cells are preserved during conversion. You can also obtain diagnostic information on the mesh, including memory usage and simplex, topological, and domain information. You can find out the number of nodes, faces, and cells in the mesh, determine the minimum and maximum cell volumes in the domain, and check for the proper numbers of nodes and faces per cell. These and other capabilities are described in the following sections.

5.1. Mesh Topologies
5.2. Mesh Requirements and Considerations
5.3. Mesh Sources
5.4. Non-Conformal Meshes
5.5. Checking the Mesh
5.6. Reporting Mesh Statistics
5.7. Converting the Mesh to a Polyhedral Mesh
5.8. Modifying the Mesh

See Adapting the Mesh (p. 1545) for information about adapting the mesh based on solution data and related functions, and Mesh Partitioning and Load Balancing (p. 1852) for details on partitioning the mesh for parallel processing.

5.1. Mesh Topologies

As an unstructured solver, ANSYS Fluent uses internal data structures to assign an order to the cells, faces, and grid points in a mesh and to maintain contact between adjacent cells. Therefore, it does not require i,j,k indexing to locate neighboring cells. This gives you the flexibility to use the best mesh topology for your problem, as the solver does not force an overall structure or topology on the mesh.

For 2D meshes, quadrilateral and triangular cells are accepted, and for 3D meshes, hexahedral, tetrahedral, pyramid, wedge, and polyhedral cells can be used. Figure 5.1: Cell Types (p. 114) depicts each of these cell types. Both single-block and multi-block structured meshes, as well as hybrid meshes containing quadrilateral and triangular cells or hexahedral, tetrahedral, pyramid, and wedge cells are acceptable. ANSYS Fluent also accepts meshes with hanging nodes (that is, nodes on edges and faces that are not vertices of all the cells sharing those edges or faces) and hanging edges (that is, edges on faces that do not act as edges for both of the cells sharing those faces), although you may need to remove the hanging nodes/edges from interior walls. See Hanging Node Adaption in the Theory Guide for information about acceptable hanging nodes, and Using the tpoly Filter to Remove Hanging Nodes/Edges (p. 141) and Converting Cells with Hanging Nodes / Edges to Polyhedra (p. 174) for details on removing hanging nodes/edges. Meshes with non-conformal boundaries (that is, meshes with multiple subdomains in which the mesh node locations at the internal subdomain boundaries are not identical) are also acceptable. For details, see Non-Conformal Meshes (p. 148).
Some examples of meshes that are valid for ANSYS Fluent are presented in Examples of Acceptable Mesh Topologies (p. 114). Different cell shapes and their face-node connectivity are explained in Face-Node Connectivity in ANSYS Fluent (p. 119). Choosing the Appropriate Mesh Type (p. 126) explains how to choose the mesh type that is best suited for your problem.

### 5.1.1. Examples of Acceptable Mesh Topologies

ANSYS Fluent can solve problems on a wide variety of meshes. Figure 5.2: Structured Quadrilateral Mesh for an Airfoil (p. 115)-Figure 5.13: Polyhedral Mesh (p. 119) show examples of meshes that are valid for ANSYS Fluent.
O-type meshes, meshes with zero-thickness walls, C-type meshes, conformal block-structured meshes, multiblock structured meshes, non-conformal meshes, and unstructured triangular, tetrahedral, quadrilateral, hexahedral, and polyhedral meshes are all acceptable.

**Note**

Though ANSYS Fluent does not require a cyclic branch cut in an O-type mesh, it will accept a mesh that contains one.

**Figure 5.2: Structured Quadrilateral Mesh for an Airfoil**

**Figure 5.3: Unstructured Quadrilateral Mesh**

5.1.2. Face-Node Connectivity in ANSYS Fluent

This section contains information about the connectivity of faces and their related nodes in terms of node number and face number.

Face-node connectivity for the following cell shapes is explained here:

- triangular (Figure 5.14: Face and Node Numbering for Triangular Cells (p. 120))
- quadrilateral (Figure 5.15: Face and Node Numbering for Quadrilateral Cells (p. 121))
- tetrahedral (Figure 5.16: Face and Node Numbering for Tetrahedral Cells (p. 122))
- wedge (Figure 5.17: Face and Node Numbering for Wedge Cells (p. 123))
- pyramidal (Figure 5.18: Face and Node Numbering for Pyramidal Cells (p. 124))
- hex (Figure 5.19: Face and Node Numbering for Hex Cells (p. 125))
- polyhedral (Figure 5.20: An Example of a Polyhedral Cell (p. 126))

This information is useful in interfacing with ANSYS Fluent.

5.1.2.7. Face-Node Connectivity for Polyhedral Cells

Figure 5.20: An Example of a Polyhedral Cell

For polyhedral cells, there is no explicit face and node numbering as with the other cell types.

5.1.3. Choosing the Appropriate Mesh Type

ANSYS Fluent can use meshes comprised of triangular or quadrilateral cells (or a combination of the two) in 2D, and tetrahedral, hexahedral, polyhedral, pyramid, or wedge cells (or a combination of these) in 3D. The choice of which mesh type to use will depend on your application. When choosing mesh type, consider the following issues:

• setup time
• computational expense
• numerical diffusion

5.1.3.1. Setup Time

Many flow problems solved in engineering practice involve complex geometries. The creation of structured or block-structured meshes (consisting of quadrilateral or hexahedral elements) for such problems can be extremely time-consuming if not impossible. Therefore, setup time for complex geometries is the major motivation for using unstructured meshes employing triangular or tetrahedral cells. However, if your geometry is relatively simple, there may be no saving in setup time with either approach.
Other risks of using structured or block-structured meshes with complicated geometries include the oversimplification of the geometry, mesh quality issues, and a less efficient mesh distribution (for example, fine resolution in areas of less importance) that results in a high cell count.

If you already have a mesh created for a structured code, it will save you time to use this mesh in ANSYS Fluent rather than regenerate it. This can be a motivation for using quadrilateral or hexahedral cells in your ANSYS Fluent simulation.

**Note**

ANSYS Fluent has a range of filters that allow you to import structured meshes from other codes, including Fluent 4. For details, see Mesh Sources (p. 133).

### 5.1.3.2. Computational Expense

When geometries are complex or the range of length scales of the flow is large, a triangular/tetrahedral mesh can be created with far fewer cells than the equivalent mesh consisting of quadrilateral/hexahedral elements. This is because a triangular/tetrahedral mesh allows clustering of cells in selected regions of the flow domain. Structured quadrilateral/hexahedral meshes will generally force cells to be placed in regions where they are not needed. Unstructured quadrilateral/hexahedral meshes offer many of the advantages of triangular/tetrahedral meshes for moderately-complex geometries.

A characteristic of quadrilateral/hexahedral elements that might make them more economical in some situations is that they permit a much larger aspect ratio than triangular/tetrahedral cells. A large aspect ratio in a triangular/tetrahedral cell will invariably affect the skewness of the cell, which is undesirable as it may impede accuracy and convergence. Therefore, if you have a relatively simple geometry in which the flow conforms well to the shape of the geometry, such as a long thin duct, use a mesh of high-aspect-ratio quadrilateral/hexahedral cells. The mesh is likely to have far fewer cells than if you use triangular/tetrahedral cells.

Converting the entire domain of your (tetrahedral) mesh to a polyhedral mesh will result in a lower cell count than your original mesh. Although the result is a coarser mesh, convergence will generally be faster, possibly saving you some computational expense.

In summary, the following practices are generally recommended:

- For simple geometries, use quadrilateral/hexahedral meshes.
- For moderately complex geometries, use unstructured quadrilateral/hexahedral meshes.
- For relatively complex geometries, use triangular/tetrahedral meshes with wedge elements in the boundary layers.
- For extremely complex geometries, use pure triangular/tetrahedral meshes.

### 5.1.3.3. Numerical Diffusion

A dominant source of error in multidimensional situations is numerical diffusion (false diffusion). The term *false diffusion* is used because the diffusion is not a real phenomenon, yet its effect on a flow calculation is analogous to that of increasing the real diffusion coefficient.

The following comments can be made about numerical diffusion:
• Numerical diffusion is most noticeable when the real diffusion is small, that is, when the situation is convection-dominated.

• All practical numerical schemes for solving fluid flow contain a finite amount of numerical diffusion. This is because numerical diffusion arises from truncation errors that are a consequence of representing the fluid flow equations in discrete form.

• The second-order and the MUSCL discretization scheme used in ANSYS Fluent can help reduce the effects of numerical diffusion on the solution.

• The amount of numerical diffusion is inversely related to the resolution of the mesh. Therefore, one way of dealing with numerical diffusion is to refine the mesh.

• Numerical diffusion is minimized when the flow is aligned with the mesh.

This is the most relevant to the choice of the mesh. If you use a triangular/tetrahedral mesh, the flow can never be aligned with the mesh. If you use a quadrilateral/hexahedral mesh, this situation might occur, but not for complex flows. It is only in a simple flow, such as the flow through a long duct, in which you can rely on a quadrilateral/hexahedral mesh to minimize numerical diffusion. In such situations, it is advantageous to use a quadrilateral/hexahedral mesh, since you will be able to get a better solution with fewer cells than if you were using a triangular/tetrahedral mesh.

• If you would like higher resolution for a gradient that is perpendicular to a wall, you can create prism layers with higher aspect ratios near the wall.

5.2. Mesh Requirements and Considerations

This section contains information about special geometry/mesh requirements and general comments on mesh quality.

5.2.1. Geometry/Mesh Requirements

5.2.2. Mesh Quality

5.2.1. Geometry/Mesh Requirements

You should be aware of the following geometry setup and mesh construction requirements at the beginning of your problem setup:

• Axisymmetric geometries must be defined such that the axis of rotation is the \( x \) axis of the Cartesian coordinates used to define the geometry (Figure 5.21: Setup of Axisymmetric Geometries with the \( x \) Axis as the Centerline (p. 129)).
• ANSYS Fluent allows you to set up periodic boundaries using either conformal or non-conformal periodic zones. For conformal periodic boundaries, the periodic zones must have identical meshes.

The conformal periodic boundaries can be created in the meshing mode of Fluent or GAMBIT when you are generating the volume mesh. See the Fluent Meshing User’s Guide or the GAMBIT Modeling Guide for more information. Alternatively, you can create the conformal periodic boundaries in the solution mode of Fluent using the mesh/modify-zones/make-periodic text command. For details, see Creating Conformal Periodic Zones (p. 184).

Although Fluent meshing mode and GAMBIT can produce true periodic boundaries, most CAD packages do not. If your mesh was created in such a package, set up a non-conformal interface with the periodic boundary condition option enabled in Fluent. For details, see The Periodic Boundary Condition Option (p. 151).

5.2.2. Mesh Quality

The quality of the mesh plays a significant role in the accuracy and stability of the numerical computation. Regardless of the type of mesh used in your domain, checking the quality of your mesh is essential. One important indicator of mesh quality that ANSYS Fluent allows you to check is a quantity referred to as the orthogonal quality. In order to determine the orthogonal quality of a given cell, the following quantities are calculated for each face \( i \):

- the normalized dot product of the area vector of a face \( \overrightarrow{A}_i \) and a vector from the centroid of the cell to the centroid of that face \( \overrightarrow{f}_i \):
  \[
  \frac{\overrightarrow{A}_i \cdot \overrightarrow{f}_i}{|\overrightarrow{A}_i| \cdot |\overrightarrow{f}_i|}
  \]  
  (5.1)

- the normalized dot product of the area vector of a face \( \overrightarrow{A}_i \) and a vector from the centroid of the cell to the centroid of the adjacent cell that shares that face \( \overrightarrow{c}_i \):
  \[
  \frac{\overrightarrow{A}_i \cdot \overrightarrow{c}_i}{|\overrightarrow{A}_i| \cdot |\overrightarrow{c}_i|}
  \]  
  (5.2)
The minimum value that results from calculating Equation 5.1 (p. 129) and Equation 5.2 (p. 129) for all of the faces is then defined as the orthogonal quality for the cell. Therefore, the worst cells will have an orthogonal quality closer to 0 and the best cells will have an orthogonal quality closer to 1. Figure 5.22: The Vectors Used to Compute Orthogonal Quality (p. 130) illustrates the relevant vectors, and is an example where Equation 5.2 (p. 129) produces the minimum value and therefore determines the orthogonal quality.

**Figure 5.22: The Vectors Used to Compute Orthogonal Quality**

Another important indicator of the mesh quality is the aspect ratio. The aspect ratio is a measure of the stretching of a cell. It is computed as the ratio of the maximum value to the minimum value of any of the following distances: the normal distances between the cell centroid and face centroids (computed as a dot product of the distance vector and the face normal), and the distances between the cell centroid and nodes. For a unit cube (see Figure 5.23: Calculating the Aspect Ratio for a Unit Cube (p. 131)), the maximum distance is 0.866, and the minimum distance is 0.5, so the aspect ratio is 1.732. This type of definition can be applied on any type of mesh, including polyhedral.
To check the quality of your mesh, you can use the **Report Quality** button in the **General** task page:

**General → Report Quality**

A message will be displayed in the console, such as the example that follows:

Mesh Quality:
- Orthogonal Quality ranges from 0 to 1, where values close to 0 correspond to low quality.
- Minimum Orthogonal Quality = 6.07960e-01
- Maximum Aspect Ratio = 5.42664e+00

If you would like more information about the quality displayed in the console (including additional quality metrics and the zones that have the cells with the lowest quality), set the `mesh/check-verbosity` text command to 2 (valid values are 0, 1, 2) prior to using the **Report Quality** button.

For information about how to improve poor quality cells, see **Repairing Meshes (p. 164)**.

When evaluating whether the quality of your mesh is sufficient for the problem you are modeling, it is important to consider attributes such as mesh element distribution, cell shape, smoothness, and flow-field dependency. These attributes are described in the sections that follow.

### 5.2.2.1. Mesh Element Distribution

Since you are discretely defining a continuous domain, the degree to which the salient features of the flow (such as shear layers, separated regions, shock waves, boundary layers, and mixing zones) are resolved depends on the density and distribution of mesh elements. In many cases, poor resolution in critical regions can dramatically affect results. For example, the prediction of separation due to an adverse pressure gradient depends heavily on the resolution of the boundary layer upstream of the point of separation.

Resolution of the boundary layer (that is, mesh spacing near walls) also plays a significant role in the accuracy of the computed wall shear stress and heat transfer coefficient. This is particularly true in laminar flows where the mesh adjacent to the wall should obey

\[
\frac{H_{\infty}}{\nu x} \leq 1
\]  

(5.3)
where

\[ y_p = \text{distance to the wall from the adjacent cell centroid} \]
\[ u_\infty = \text{free-stream velocity} \]
\[ \nu = \text{kinematic viscosity of the fluid} \]
\[ x = \text{distance along the wall from the starting point of the boundary layer} \]

Equation 5.3 (p. 131) is based upon the Blasius solution for laminar flow over a flat plate at zero incidence [87] (p. 2561).

Proper resolution of the mesh for turbulent flows is also very important. Due to the strong interaction of the mean flow and turbulence, the numerical results for turbulent flows tend to be more susceptible to mesh element distribution than those for laminar flows. In the near-wall region, different mesh resolutions are required depending on the near-wall model being used. See Model Hierarchy (p. 708) for guidelines.

In general, no flow passage should be represented by fewer than 5 cells. Most cases will require many more cells to adequately resolve the passage. In regions of large gradients, as in shear layers or mixing zones, the mesh should be fine enough to minimize the change in the flow variables from cell to cell. Unfortunately, it is very difficult to determine the locations of important flow features in advance. Moreover, the mesh resolution in most complicated 3D flow fields will be constrained by CPU time and computer resource limitations (that is, memory and disk space). Although accuracy increases with larger meshes, the CPU and memory requirements to compute the solution and postprocess the results also increase. Solution-adaptive mesh refinement can be used to increase and/or decrease mesh density based on the evolving flow field, and therefore provides the potential for more economical use of grid points (and hence reduced time and resource requirements). See Adapting the Mesh (p. 1545) for information on solution adaption.

5.2.2.2. Cell Quality

The quality of the cell (including its orthogonal quality, aspect ratio, and skewness) also has a significant impact on the accuracy of the numerical solution.

- **Orthogonal quality** is computed for cells using the vector from the cell centroid to each of its faces, the corresponding face area vector, and the vector from the cell centroid to the centroids of each of the adjacent cells (see Equation 5.1 (p. 129), Equation 5.2 (p. 129), and Figure 5.22: The Vectors Used to Compute Orthogonal Quality (p. 130)). The worst cells will have an orthogonal quality closer to 0, with the best cells closer to 1. The minimum orthogonal quality for all types of cells should be more than 0.01, with an average value that is significantly higher.

- **Aspect ratio** is a measure of the stretching of the cell. As discussed in Computational Expense (p. 127), for highly anisotropic flows, extreme aspect ratios may yield accurate results with fewer cells. Generally, it is best to avoid sudden and large changes in cell aspect ratios in areas where the flow field exhibit large changes or strong gradients.

- **Skewness** is defined as the difference between the shape of the cell and the shape of an equilateral cell of equivalent volume. Highly skewed cells can decrease accuracy and destabilize the solution. For example, optimal quadrilateral meshes will have vertex angles close to 90 degrees, while triangular meshes should preferably have angles of close to 60 degrees and have all angles less than 90 degrees. A general rule is that the maximum skewness for a triangular/tetrahedral mesh in most flows should be kept below 0.95, with an average value that is significantly lower. A maximum value above 0.95 may lead to convergence...
difficulties and may require changing the solver controls, such as reducing under-relaxation factors and/or switching to the pressure-based coupled solver.

Cell size change and face warp are additional quality measure that could affect stability and accuracy. See the Fluent Meshing User’s Guide for more details.

**5.2.2.3. Smoothness**

Truncation error is the difference between the partial derivatives in the governing equations and their discrete approximations. Rapid changes in cell volume between adjacent cells translate into larger truncation errors. ANSYS Fluent provides the capability to improve the smoothness by refining the mesh based on the change in cell volume or the gradient of cell volume. For information on refining the mesh based on change in cell volume, see Gradient Adaption (p. 1552) and Volume Adaption (p. 1558).

**5.2.2.4. Flow-Field Dependency**

The effect of resolution, smoothness, and cell shape on the accuracy and stability of the solution process is dependent on the flow field being simulated. For example, very skewed cells can be tolerated in benign flow regions, but can be very damaging in regions with strong flow gradients.

Since the locations of strong flow gradients generally cannot be determined a priori, you should strive to achieve a high-quality mesh over the entire flow domain.

**5.3. Mesh Sources**

Since ANSYS Fluent can handle a number of different mesh topologies, there are many sources from which you can obtain a mesh to be used in your simulation. You can generate a mesh using ANSYS Meshing, the meshing mode of Fluent, TGrid, GAMBIT, GeoMesh, PreBFC, ICEM CFD, I-deas, NASTRAN, PATRAN, ARIES, Mechanical APDL, CFX, or other preprocessors. You can also use the mesh contained in a Fluent/UNS, RAMPANT, or Fluent 4 case file. You can also prepare multiple mesh files and combine them to create a single mesh.

5.3.1. ANSYS Meshing Mesh Files
5.3.2. Fluent Meshing Mode Mesh Files
5.3.3. TGrid Mesh Files
5.3.4. GAMBIT Mesh Files
5.3.5. GeoMesh Mesh Files
5.3.6. PreBFC Mesh Files
5.3.7. ICEM CFD Mesh Files
5.3.8. I-deas Universal Files
5.3.9. NASTRAN Files
5.3.10. PATRAN Neutral Files
5.3.11. Mechanical APDL Files
5.3.12. CFX Files
5.3.13. Using the fe2ram Filter to Convert Files
5.3.14. Using the tpoly Filter to Remove Hanging Nodes/Edges
5.3.15. Fluent/UNS and RAMPANT Case Files
5.3.16. Fluent 4 Case Files
5.3.17. ANSYS FIDAP Neutral Files
5.3.18. Reading Multiple Mesh/Case/Data Files
5.3.19. Reading Surface Mesh Files
5.3.1. ANSYS Meshing Mesh Files

You can use ANSYS Meshing to create your mesh. Follow the meshing procedure and export to the ANSYS Fluent mesh format (see Fluent Mesh Export in the ANSYS Meshing User's Guide for details). To import the mesh into Fluent, use the File/Read/Mesh... menu item (as described in Reading Mesh Files (p. 46)).

5.3.2. Fluent Meshing Mode Mesh Files

You can use the meshing mode of Fluent (which was previously a standalone program named TGrid) to create 3D unstructured triangular/tetrahedral meshes from boundary or surface meshes. Switch to meshing mode and then follow the meshing procedure described in the Fluent Meshing User's Guide. You can save your mesh using the File/Write/Mesh... menu item.

Then switch to the solution mode to set up the case file for the transferred mesh, or import the saved mesh into a new Fluent session using the File/Read/Mesh... menu item (as described in Reading Mesh Files (p. 46)).

For information about switching between meshing and solution modes, see Switching Between Meshing and Solution Modes in the Getting Started Guide.

5.3.3. TGrid Mesh Files

Prior to version 14.5, TGrid was a standalone product that was used to create 3D unstructured triangular/tetrahedral meshes from boundary or surface meshes. TGrid has been integrated as the Fluent meshing mode. To import meshes created by TGrid into Fluent, use the File/Read/Mesh... menu item (as described in Reading Mesh Files (p. 46)).

5.3.4. GAMBIT Mesh Files

You can use GAMBIT to create 2D and 3D structured/unstructured/hybrid meshes. To create any of these meshes for ANSYS Fluent, follow the procedure described in the GAMBIT Modeling Guide, and export your mesh in Fluent 5/6 format. All such meshes can be imported directly into ANSYS Fluent using the File/Read/Mesh... menu item, as described in Reading Mesh Files (p. 46).

5.3.5. GeoMesh Mesh Files

You can use GeoMesh to create complete 2D quadrilateral or triangular meshes, 3D hexahedral meshes, and triangular surface meshes for 3D tetrahedral meshes. To create any of these meshes for ANSYS Fluent, follow the procedure described in the GeoMesh User's Guide.

To complete the generation of a 3D tetrahedral mesh, read the surface mesh into the meshing mode of Fluent and generate the volume mesh there (see the Fluent Meshing User's Guide for details). All other meshes can be read directly into the solution mode of Fluent. Use the File/Read/Mesh... menu item to read the mesh files, as described in Reading Mesh Files (p. 46).

5.3.6. PreBFC Mesh Files

You can use PreBFC to create two different types of meshes for ANSYS Fluent, structured quadrilateral/hexahedral and unstructured triangular/tetrahedral.
5.3.6.1. Structured Mesh Files

To generate a structured 2D or 3D mesh, follow the procedure described in the PreBFC User's Guide (Chapters 6 and 7). The resulting mesh will contain quadrilateral (2D) or hexahedral (3D) elements. Do not specify more than 70 wall zones and 35 inlet zones.

To import the mesh, use the File/Import/PreBFC File... menu item, as described in PreBFC Files (p. 68).

To manually convert a file in PreBFC format to a mesh file suitable for ANSYS Fluent, enter the following command:

```
utility fl42seg input_filename output_filename
```

The output file produced can be read into ANSYS Fluent using the File/Read/Mesh... menu item, as described in Reading Mesh Files (p. 46).

5.3.6.2. Unstructured Triangular and Tetrahedral Mesh Files

To generate an unstructured 2D mesh, follow the procedure described in the PreBFC User's Guide. Save the mesh file in the RAMPANT format using the MESH-RAMPANT/TGRID command. The current ANSYS Fluent format is the same as the RAMPANT format. The resulting mesh will contain triangular elements.

To import the mesh, use the File/Read/Mesh... menu item, as described in Reading Mesh Files (p. 46).

To generate a 3D unstructured tetrahedral mesh, follow the procedure described in Chapter 8 of the PreBFC User's Guide for generating a surface mesh. Then read the surface mesh into the meshing mode of Fluent, and complete the mesh generation there. See the Fluent Meshing User's Guide for details.

5.3.7. ICEM CFD Mesh Files

You can use ICEM CFD to create structured meshes in Fluent 4 format and unstructured meshes in RAMPANT format.

- To import a Fluent 4 mesh, follow the instructions in Fluent 4 Case Files (p. 143).
- To import a RAMPANT mesh, use the File/Read/Mesh... menu item, as described in Reading Mesh Files (p. 46).

The current ANSYS Fluent format is the same as the RAMPANT format, not the Fluent 4 format. After reading a triangular or tetrahedral ICEM CFD volume mesh, perform smoothing and swapping (as described in Improving the Mesh by Smoothing and Swapping (p. 1572)) to improve its quality.

5.3.8. I-deas Universal Files

You can import an I-deas Universal file into ANSYS Fluent in three different ways.

- Generate an I-deas surface or volume mesh containing triangular, quadrilateral, tetrahedral, wedge and/or hexahedral elements. Import it into the meshing mode of Fluent using the commands described in the Fluent Meshing User's Guide. Adhere to the restrictions described in Appendix B of the Fluent Meshing User's Guide. In meshing mode, complete the mesh generation (if necessary); then you can switch to the solution mode of Fluent or read it into a new Fluent session as described in Fluent Meshing Mode Mesh Files (p. 134).
• Generate an I-deas volume mesh with linear triangular, quadrilateral, tetrahedral, wedge, or hexahedral elements. Import it directly using the **File/Import/I-deas Universal**... menu item, as described in **I-deas Universal Files** (p. 65).

• Generate an I-deas volume mesh with linear triangular, quadrilateral, tetrahedral, wedge, or hexahedral elements. Use the **fe2ram** filter to convert the Universal file to the format used by ANSYS Fluent. To convert an input file in I-deas Universal format to an output file in ANSYS Fluent format, follow the instructions below in **Using the fe2ram Filter to Convert Files** (p. 141). After the output file is written, read it into ANSYS Fluent using the **File/Read/Mesh...** menu item, as described in **Reading Mesh Files** (p. 46).

### 5.3.8.1. Recognized I-deas Datasets

The following Universal file datasets are recognized by the ANSYS Fluent mesh import utility:

- **Node Coordinates** dataset number 15, 781, 2411
- **Elements** dataset number 71, 780, 2412
- **Permanent Groups** dataset number 752, 2417, 2429, 2430, 2432, 2435

For 2D volume meshes, the elements must exist in a constant z plane.

---

**Note**

The mesh area or mesh volume datasets are *not* recognized. This implies that writing multiple mesh areas/volumes to a single Universal file may confuse ANSYS Fluent.

### 5.3.8.2. Grouping Nodes to Create Face Zones

Nodes are grouped in I-deas using the **Group** command to create boundary face zones. In ANSYS Fluent, boundary conditions are applied to each zone. Faces that contain the nodes in a group are gathered into a single zone. It is important not to group nodes of internal faces with nodes of boundary faces.

One technique is to generate groups automatically based on curves or mesh areas—that is, every curve or mesh area will be a different zone in ANSYS Fluent. You may also create the groups manually, generating groups consisting of all nodes related to a given curve (2D) or mesh area (3D).

### 5.3.8.3. Grouping Elements to Create Cell Zones

Elements in I-deas are grouped using the **Group** command to create the multiple cell zones. All elements grouped together are placed in a single cell zone in ANSYS Fluent. If the elements are not grouped, ANSYS Fluent will place all the cells into a single zone.

### 5.3.8.4. Deleting Duplicate Nodes

I-deas may generate duplicate or coincident nodes in the process of creating elements. These nodes must be removed in I-deas before writing the universal file for import into ANSYS Fluent.

### 5.3.9. NASTRAN Files

There are three different ways in which you can import a NASTRAN file into ANSYS Fluent:
Mesh Sources

• You can generate a NASTRAN surface or volume mesh containing triangular, quadrilateral, tetrahedral, wedge, and/or hexahedral elements, and import it into the meshing mode of Fluent using the commands described in the Fluent Meshing User’s Guide. Adhere to the restrictions described in Appendix B of the Fluent Meshing User’s Guide. In meshing mode, complete the mesh generation (if necessary); then you can switch to the solution mode of Fluent or read it into a new Fluent session as described in Fluent Meshing Mode Mesh Files (p. 134).

• You can generate a NASTRAN volume mesh with linear triangular, quadrilateral, tetrahedral, wedge, or hexahedral elements, and import it directly using the File/Import/NASTRAN menu item, as described in NASTRAN Files (p. 66).

• You can generate a NASTRAN volume mesh with linear triangular, quadrilateral, tetrahedral, wedge, or hexahedral elements. Then use the fe2ram filter to convert the NASTRAN file to the format used by ANSYS Fluent. To convert an input file in NASTRAN format to an output file in ANSYS Fluent format, follow the instructions below in Using the fe2ram Filter to Convert Files (p. 141). After the output file has been written, you can read it into ANSYS Fluent using the File/Read/Mesh... menu item, as described in Reading Mesh Files (p. 46).

After reading a triangular or tetrahedral NASTRAN volume mesh using the latter methods perform smoothing and swapping (as described in Improving the Mesh by Smoothing and Swapping (p. 1572)) to improve its quality.

5.3.9.1. Recognized NASTRAN Bulk Data Entries

The following NASTRAN file datasets are recognized by the ANSYS Fluent mesh import utility:

• GRID single-precision node coordinates
• GRID* double-precision node coordinates
• CBAR line elements
• CTETRA, CTRIA3 tetrahedral and triangular elements
• CHEXA, CQUAD4, CPENTA hexahedral, quadrilateral, and wedge elements

For 2D volume meshes, the elements must exist in a constant z plane.

5.3.9.2. Deleting Duplicate Nodes

NASTRAN may generate duplicate or coincident nodes in the process of creating elements. These nodes must be removed in NASTRAN before writing the file for import into ANSYS Fluent.

5.3.10. PATRAN Neutral Files

There are three different ways in which you can import a PATRAN Neutral file into ANSYS Fluent.

• You can generate a PATRAN surface or volume mesh containing triangular, quadrilateral, tetrahedral, wedge, and/or hexahedral elements, and import it into the meshing mode of Fluent using the commands described in the Fluent Meshing User’s Guide. Adhere to the restrictions described in Appendix B of the Fluent Meshing User’s Guide. In meshing mode, complete the mesh generation (if necessary); then you can switch to the solution mode of Fluent or read it into a new Fluent session as described in Fluent Meshing Mode Mesh Files (p. 134).
You can generate a PATRAN volume mesh with linear triangular, quadrilateral, tetrahedral, wedge, or hexahedral elements (grouping nodes with the same component-group name) and import it directly to ANSYS Fluent by selecting the **File/Import/PATRAN** menu item, as described in **PATRAN Neutral Files (p. 66)**.

You can generate a PATRAN volume mesh with linear triangular, quadrilateral, tetrahedral, wedge, or hexahedral elements and then use the *fe2ram* filter to convert the Neutral file into the format used by ANSYS Fluent. To convert an input file in PATRAN Neutral format to an output file in ANSYS Fluent format, follow the instructions below in **Using the *fe2ram* Filter to Convert Files (p. 141)**. After the output file has been written, you can read it into ANSYS Fluent using the **File/Read/Mesh...** menu item, as described in **Reading Mesh Files (p. 46)**.

After reading a triangular or tetrahedral PATRAN volume mesh using the latter methods perform smoothing and swapping (as described in **Improving the Mesh by Smoothing and Swapping (p. 1572)**) to improve its quality.

---

**Important**

To retain a zone type during PATRAN Neutral file import, add the abbreviated form of the “zone-type” before the “zone-name”, as shown below:

<table>
<thead>
<tr>
<th>Zone Type in ANSYS Fluent</th>
<th>Zone Name for PATRAN export (zone-type) - (zone-name)</th>
</tr>
</thead>
<tbody>
<tr>
<td>mass-flow-inlet</td>
<td>m-f-i-zone-name</td>
</tr>
<tr>
<td>pressure-outlet</td>
<td>p-o-zone-name</td>
</tr>
<tr>
<td>fan</td>
<td>fan-zone-name</td>
</tr>
<tr>
<td>velocity-inlet</td>
<td>v-i-zone-name</td>
</tr>
<tr>
<td>pressure-far-field</td>
<td>p-f-f-zone-name</td>
</tr>
<tr>
<td>solid</td>
<td>solid-zone-name</td>
</tr>
<tr>
<td>fluid</td>
<td>fluid-zone-name</td>
</tr>
</tbody>
</table>

### 5.3.10.1. Recognized PATRAN Datasets

The following PATRAN Neutral file packet types are recognized by the ANSYS Fluent mesh import utility:

- **Node Data** Packet Type 01
- **Element Data** Packet Type 02
- **Distributed Load Data** Packet Type 06
- **Node Temperature Data** Packet Type 10
- **Name Components** Packet Type 21
- **File Header** Packet Type 25

For 2D volume meshes, the elements must exist in a constant $z$ plane.
5.3.10.2. Grouping Elements to Create Cell Zones

Elements are grouped in PATRAN using the Named Component command to create the multiple cell zones. All elements grouped together are placed in a single cell zone in ANSYS Fluent. If the elements are not grouped, ANSYS Fluent will place all the cells into a single zone.

5.3.11. Mechanical APDL Files

There are three different ways in which you can import a Mechanical APDL file into ANSYS Fluent.

• You can generate a surface or volume mesh containing triangular, quadrilateral, tetrahedral, wedge, or hexahedral elements using Mechanical APDL or ARIES, and import it into the meshing mode of Fluent using the commands described in the Fluent Meshing User’s Guide. Adhere to the restrictions described in Appendix B of the Fluent Meshing User’s Guide. In meshing mode, complete the mesh generation (if necessary); then you can switch to the solution mode of Fluent or read it into a new Fluent session as described in Fluent Meshing Mode Mesh Files (p. 134).

• You can generate a Mechanical APDL volume mesh with linear triangular, quadrilateral, tetrahedral, wedge, or hexahedral elements, as well as with higher order elements like 20 node hexahedron, SOLID92, and SOLID187. Then import it directly to ANSYS Fluent using the File/Import/Mechanical APDL menu item, as described in Mechanical APDL Files (p. 66).

The higher order elements will be converted to their corresponding linear elements during the import in ANSYS Fluent.

• You can generate a Mechanical APDL volume mesh with linear triangular, quadrilateral, tetrahedral, wedge, or hexahedral elements, and then use the fe2ram filter to convert the Mechanical APDL file into the format used by ANSYS Fluent. To convert an input file in ANSYS 5.4 or 5.5 format to an output file in ANSYS Fluent format, follow the instructions in Using the fe2ram Filter to Convert Files (p. 141). After the output file has been written, you can read it into ANSYS Fluent using the File/Read/Mesh... menu item, as described in Reading Mesh Files (p. 46).

After reading a triangular or tetrahedral volume mesh using method 2 or 3 above, you should perform smoothing and swapping (as described in Improving the Mesh by Smoothing and Swapping (p. 1572)) to improve its quality.

5.3.11.1. Recognized ANSYS 5.4 and 5.5 Datasets

ANSYS Fluent can import mesh files from ANSYS 5.4 and 5.5 (.cdb files), retaining original boundary names. The following ANSYS file datasets are recognized by the ANSYS Fluent mesh import utility:

• NBLOCK node block data
• EBLOCK element block data
• CMBLOCK element/node grouping

The elements must be STIF63 linear shell elements. In addition, if element data without an explicit element ID is used, the filter assumes sequential numbering of the elements when creating the zones.

5.3.12. CFX Files

You can import the meshes from 3D CFX files, such as definition (.def) and result (.res) files into ANSYS Fluent, using the File/Import/CFX menu item, as described in CFX Files (p. 62). The fe2ram
utility is used as the import filter, which can be used as a stand-alone program to obtain an ANSYS Fluent mesh file. See Using the fe2ram Filter to Convert Files (p. 141) for information about fe2ram.

**Important**

Note that you have the ability to import only the mesh from a CFX file, and not any results or data.

When importing a mesh from a CFX definition or results file, select whether you want the ANSYS Fluent zones to be created from the physics data objects or the primitive mesh region objects. The former option is the default and is called “Zoning by CCL” and the latter option is called “Zoning by Group.” This will allow you to choose the type of mesh topology you would like to preserve when importing the file:

- If you want zones to be created from the physics data objects, enable **Create Zones from CCL Physics Data** in the Select File dialog box.

- If you want zones to be created from the primitive mesh region objects, disable **Create Zones from CCL Physics Data** in the Select File dialog box. This will result in the group zoning.

**Important**

The primitive mesh topology may contain additional regions that do not appear in the physics definition.

The default import method is the **Create Zones from CCL Physics Data** method. This method will not import CFX subdomain regions, however, the zoning by group method can import subdomain regions.

The 3D element set corresponding to zones/domains present in these files are imported as cell zones in ANSYS Fluent. They may contain tetrahedral, pyramidal, wedge, and hexahedral elements. The boundary zones in these files are a group of faces with a boundary condition name/type and are imported as face zones with the boundary condition name/type retained in ANSYS Fluent. The following boundary condition types are retained:

- **inlet**
- **outlet**
- **symmetry**
- **interface**
- **wall**

The boundaries of type **Interface** may be conformal or non-conformal. If they are non-conformal, they are retained. However, conformal interfaces contain coincident nodes which are merged and changed to type **Interior**. For some cases, for the merge to work correctly, the merge tolerance may need to be adjusted. Alternatively, the **Fuse Face Zones Dialog Box** (p. 2408) in ANSYS Fluent can be used to merge the conformal interfaces. For details, see **Fusing Face Zones** (p. 182).
5.3.13. Using the fe2ram Filter to Convert Files

The fe2ram filter can be used to manually convert files of certain formats into ANSYS Fluent mesh files, which can then be read into ANSYS Fluent. To use the fe2ram filter, enter the following at a command prompt in a terminal or command window:

```
utility fe2ram [dimension] format [zoning] input_file output_file
```

**Note**

The items enclosed in square brackets are optional. Do not type the square brackets.

- `dimension` indicates the dimension of the dataset. Replace `dimension` with `-d2` to indicate that the mesh is two dimensional. For a 3D mesh, do not enter any value for `dimension`, because 3D is the default.

- `format` indicates the format of the file you want to convert. For example, replace `format` with `-tANSYS` for a Mechanical APDL file, `-tIDEAS` for an I-deas file, `-tNASTRAN` for a NASTRAN file, etc. To print a list of the formats which fe2ram can convert, type

```
utility fe2ram -cl -help.
```

**Note**

fe2ram does not support VRML 2.0 or later.

- `zoning` indicates how zones were identified in the original format. Replace `zoning` by `-zID` for a mesh that was zoned by property IDs, or `-zNONE` to ignore all zone groupings. For a mesh zoned by group, do not enter anything for `zoning`, because zoning by groups is the default.

- `input_file` is the name of the original file. `output_file` is the name of the file to which you want to write the converted mesh information.

For example, if you wanted to convert the 2D I-deas volume mesh file `sample.unv` to an output file called `sample.grd`, you will enter the following command:

```
utility fe2ram -d2 -tIDEAS sample.unv sample.grd
```

5.3.14. Using the tpoly Filter to Remove Hanging Nodes/Edges

As noted in Mesh Topologies (p. 113), ANSYS Fluent can accept meshes that contain hanging nodes or hanging edges. However, the creation of interior walls can yield an error if hanging nodes/edges are located on the zone that is turned into an interior wall. This problem can occur in the following cases:

- If you read a mesh file that has an interior (or two-sided) wall boundary condition setup, but the shadow wall has not been created yet.

- If you turn an interior surface into a wall.

- If you slit an interior surface (for example, turn it into a non-conformal interface).

Such error-producing hanging nodes / edges may be present in hexcore or CutCell meshes, for example. You can remove the hanging nodes/edges by converting the associated cells to polyhedra. Each cell
that is converted will retain the same overall dimensions, but the number of faces associated with the cell will increase. You can perform the conversion prior to reading the mesh into ANSYS Fluent by using the `tpoly` filter, or during an ANSYS Fluent session by using the `mesh/polyhedra/convert-hanging-nodes` text command (see Converting Cells with Hanging Nodes / Edges to Polyhedra (p. 174)).

When you use the `tpoly` filter, you must specify an input case file that contains a mesh with hanging nodes/edges. This file can either be in ASCII or Binary format, and the file should be unzipped. If the input file does not contain hanging nodes/edges, then none of the cells are converted to polyhedra. When you use the `tpoly` filter, you should specify an output case file name. After the input file has been processed by the `tpoly` filter, an ASCII output file is generated.

---

**Important**

The output case file resulting from a `tpoly` conversion only contains mesh information. None of the solver-related data of the input file is retained.

---

To convert a file using the `tpoly` filter, before starting ANSYS Fluent, type the following:

```
utility tpoly input_filename output_filename
```

### 5.3.14.1. Limitations

Meshes with polyhedra have the following limitations:

- The following mesh manipulation tools are not available on polyhedral meshes:
  - `extrude-face-zone` under the `modify-zone` option
  - skewness smoothing
  - swapping (will not affect polyhedral cells)

- The polyhedral cells that result from the conversion are not eligible for adaption. For more information about adaption, see Adapting the Mesh (p. 1545).

- The polyhedral cells that result from this conversion have the following limitations with regard to the update methods available for dynamic mesh problems:
  - When applying dynamic layering to a cell zone, you cannot have polyhedral cells adjacent to the moving face zone.
  - None of the remeshing methods except for CutCell zone remeshing will modify polyhedral cells.

Note that smoothing is allowed for polyhedral cells, and diffusion-based smoothing is recommended over spring-based smoothing (see Diffusion-Based Smoothing (p. 581) for details). The linearly elastic solid smoothing method is not compatible with polyhedral cells.

### 5.3.15. Fluent/UNS and RAMPANT Case Files

If you have a Fluent/UNS 3 or 4 case file or a RAMPANT 2, 3, or 4 case file and you want to run an ANSYS Fluent simulation using the same mesh, you can read it into ANSYS Fluent using the File/Read/Case... menu item, as described in Reading Fluent/UNS and RAMPANT Case and Data Files (p. 54).
5.3.16. Fluent 4 Case Files

If you have a Fluent 4 case file and you want to run an ANSYS Fluent simulation using the same mesh, import it into ANSYS Fluent using the File/Import/Fluent 4 Case File... menu item, as described in Fluent 4 Case Files (p. 67). ANSYS Fluent will read mesh information and zone types from the Fluent 4 case file.

**Important**

Fluent 4 may interpret some pressure boundaries differently from the current release of ANSYS Fluent. Check the conversion information printed out by ANSYS Fluent to see if you need to modify any boundary types.

To manually convert an input file in Fluent 4 format to an output file in the current ANSYS Fluent format, enter the following command:

```
utility fl42seg input_filename output_filename
```

After the output file has been written, you can read it into ANSYS Fluent using the File/Read/Case... menu item, as described in Reading Mesh Files (p. 46).

5.3.17. ANSYS FIDAP Neutral Files

If you have an ANSYS FIDAP Neutral file and you want to run an ANSYS Fluent simulation using the same mesh, import it using the menu item, as described in ANSYS FIDAP Neutral Files (p. 64). ANSYS Fluent will read mesh information and zone types from the ANSYS FIDAP file.

To manually convert an input file in ANSYS FIDAP format to an output file in ANSYS Fluent

```
utility fe2ram [dimension] -tFIDAP7 input_file output_file
```

The item in square brackets is optional. Do not type the square brackets. For a 2D file, replace `dimension` with `-d2`. For a 3D file, do not enter anything for `dimension`, because 3D is the default.

After the output file has been written, read it into ANSYS Fluent using the File/Read/Case... menu item, as described in Reading Mesh Files (p. 46).

5.3.18. Reading Multiple Mesh/Case/Data Files

There may be some cases in which you will need to read multiple mesh files (subdomains) to form your computational domain.

- To solve on a multiblock mesh, generate each block of the mesh in the mesh generator and save it to a separate mesh file.

- For very complicated geometries, it may be more efficient to save the mesh for each part as a separate mesh file.

The mesh node locations need not be identical at the boundaries where two separate meshes meet. ANSYS Fluent can handle non-conformal mesh interfaces. See Non-Conformal Meshes (p. 148) for details about non-conformal mesh boundaries.

There are three ways of reading multiple mesh files in ANSYS Fluent:
• Read multiple mesh files into the solution mode of Fluent.

• Read multiple mesh files into the meshing mode of Fluent.

• Use `tmerge` to manipulate the individual files and merge them into a single file that can then be read into Fluent.

### 5.3.18.1. Reading Multiple Mesh Files via the Solution Mode of Fluent

The solution mode of Fluent allows you to handle more than one mesh at a time within the same solver settings. This capability of handling multiple meshes saves time, since you can directly read in the different mesh files and start setting up the solution, without having to switch over from meshing mode or employ another tool such as `tmerge`.

The steps to take when reading more than one mesh file are:

1. Read in your first mesh file.

   - **File → Read → Mesh...**

   In the [Select File Dialog Box](p. 15) (Figure 5.24: The Select File Dialog Box), select the mesh file and click **OK**.

   ![Figure 5.24: The Select File Dialog Box](p. 144)

2. Read in your second mesh file and append it to the first mesh selected in the first step.
Mesh Sources

Mesh → Zone → Append Case File...

In The Select File Dialog Box (p. 15), select the second mesh file and click OK.

3. (optional). Display your meshes using the Mesh Display dialog box.

General → Display...

You will find that the second mesh is appended to the first.

ANSYS Fluent also allows you to append the data on the mesh. To do that, follow the procedure above. For the second step, use the following menu item:

Mesh → Zone → Append Case & Data Files...

Select the case file in The Select File Dialog Box (p. 15) (Figure 5.24: The Select File Dialog Box (p. 144)), and click OK. Both the case and data files will be appended.

Important

Reading multiple mesh and data options are available for serial and parallel cases.

5.3.18.2. Reading Multiple Mesh Files via the Meshing Mode of Fluent

1. Generate the mesh for the whole domain in the mesh generator, and save each cell zone (or block or part) to a separate mesh file for Fluent.

Important

If one (or more) of the meshes you want to import is structured (for example, a Fluent 4 mesh file), first convert it to ANSYS Fluent format using the fl42seg filter described in Fluent 4 Case Files (p. 143).

2. In the meshing mode of Fluent, combine the meshes into one mesh file.

a. Read all of the mesh files. As the mesh files are read, they will be automatically merged into a single mesh.

b. Save the merged mesh file.

See the Fluent Meshing User’s Guide for information about reading and writing files in meshing mode.

3. Switch over to the solution mode of Fluent or read the combined mesh file into a new session using the File/Read/Mesh... menu item.

For a conformal mesh, if you do not want a boundary between the adjacent cell zones, use the Fuse Face Zones dialog box to fuse the overlapping boundaries. For details, see Fusing Face Zones (p. 182).
The matching faces will be moved to a new zone with a boundary type of \textit{interior} and the original zone(s) will be discarded.

\textbf{Important}

If you are planning to use sliding meshes, or if you have non-conformal boundaries between adjacent cell zones, do not combine the overlapping zones. Instead, change the type of the two overlapping zones to \texttt{interface} (as described in Non-Conformal Meshes (p. 148)).

\section*{5.3.18.3. Reading Multiple Mesh Files via tmerge}

1. Generate the mesh for the whole domain in the mesh generator, and save each cell zone (or block or part) to a separate mesh file for ANSYS Fluent.

\textbf{Important}

If one (or more) of the meshes you want to import is structured (for example, a Fluent 4 mesh file), first convert it to ANSYS Fluent format using the \texttt{fl42seg} filter described in Fluent 4 Case Files (p. 143).

2. Before launching Fluent, use the \texttt{tmerge} filter to combine the meshes into one mesh file. The \texttt{tmerge} method allows you to rotate, scale, and/or translate the meshes before they are merged. Note that the \texttt{tmerge} filter allows you to merge large meshes with very low memory requirement.

   a. For 3D problems, type \texttt{utility tmerge -3d}. For 2D problems, type \texttt{utility tmerge -2d}.

   b. When prompted, specify the names of the input files (the separate mesh files) and the name of the output file in which to save the complete mesh. Be sure to include the \texttt{.msh} extension.

   c. For each input file, specify scaling factors, translation distances, and rotation information.

   For information about the various options available when using \texttt{tmerge}, type \texttt{utility tmerge -h}.

3. Read the combined mesh file into the solution mode of Fluent in the usual manner (using the \texttt{File/Read/Mesh...} menu item).

For a conformal mesh, if you do not want a boundary between the adjacent cell zones, use the \textbf{Fuse Face Zones} dialog box to fuse the overlapping boundaries. For details, see Fusing Face Zones (p. 182). The matching faces will be moved to a new zone with a boundary type of \texttt{interior} and the original zone(s) will be discarded.

\textbf{Important}

If you are planning to use sliding meshes, or if you have non-conformal boundaries between adjacent cell zones, do not combine the overlapping zones. Instead, change the type of the two overlapping zones to \texttt{interface} (as described in Non-Conformal Meshes (p. 148)).

In this example, scaling, translation, or rotation is not requested. Hence you can simplify the inputs to the following:
user@mymachine:~> utility tmerge -2d

Starting /ansys_inc/v150/fluent/utility/tmerge15.0/lnamd64/tmerge_2d.15.0.0

Append 2D grid files.
tmerge2D ANSYS Inc, stream

Enter name of grid file (ENTER to continue) : my1.msh
x,y scaling factor, eg. 1 1          : 1 1
x,y translation, eg. 0 1             : 0 0
rotation angle (deg), eg. 45         : 0

Enter name of grid file (ENTER to continue) : my2.msh
x,y scaling factor, eg. 1 1          : 1 1
x,y translation, eg. 0 1             : 0 0
rotation angle (deg), eg. 45          : 0

Enter name of grid file (ENTER to continue) : {Enter}

Enter name of output file            : final.msh

Appending done.

5.3.19. Reading Surface Mesh Files

Surface meshes are used as background meshes for geometry-based adaption. Perform the following steps to read the surface mesh file into ANSYS Fluent:

1. Open the **Geometry Based Adaption** dialog box.

   Adapt → Geometry...

2. Enable the **Reconstruct Geometry** option.

3. Click the **Surface Meshes...** button to open the **Surface Meshes** dialog box (Figure 5.25: The Surface Meshes Dialog Box (p. 148)).

4. In the **Surface Meshes Dialog Box (p. 2477)**, click **Read...** and select the surface mesh file using the **Select File Dialog Box (p. 15)**.

   Note that you can also display and delete the surfaces using this dialog box.
5.4. Non-Conformal Meshes

In ANSYS Fluent it is possible to use a mesh that has non-conformal interfaces, that is, boundaries between cell zones in which the mesh node locations are not identical. Such non-conformal interfaces permit the cell zones to be easily connected to each other by passing fluxes from one mesh to another. The principle requirement is that the boundary zones that comprise the non-conformal interface must overlap either partially or fully. (This requirement does not apply to non-conformal periodic boundaries.)

5.4.1. Non-Conformal Mesh Calculations
5.4.2. Non-Conformal Interface Algorithm
5.4.3. Requirements and Limitations of Non-Conformal Meshes
5.4.4. Using a Non-Conformal Mesh in ANSYS Fluent

5.4.1. Non-Conformal Mesh Calculations

To compute the flux across the non-conformal boundary, ANSYS Fluent must first compute the intersection between the interface zones that comprise the boundary. In the case of fluid-to-fluid zone interfaces and solid-to-solid zone interfaces, the resulting intersection produces an interior zone where the two interface zones overlap (see Figure 5.26: Completely Overlapping Mesh Interface Intersection (p. 149)). In the case of fluid-to-solid zone interfaces, a coupled wall zone is produced where the interface zones overlap (see The Coupled Wall Option (p. 154)).

Note

If the zones on either side of a solid-to-solid interface are of differing materials, the interface must be treated as a coupled wall instead of as an interior. If Fluent detects this scenario during case read or initialization it will issue a warning and prompt you to run the mesh/modify-zones/slit-interior-between-diff-solids TUI command.
If one of the interface zones extends beyond the other (Figure 5.27: Partially Overlapping Mesh Interface Intersection (p. 149)), by default ANSYS Fluent will create additional wall zones for the portion(s) of the boundary where the two interface zones do not overlap.

Fluxes across the mesh interface are computed using the faces resulting from the intersection of the two interface zones, not from the interface zone faces.

In the example shown in Figure 5.28: Two-Dimensional Non-Conformal Mesh Interface (p. 150), the interface zones are composed of faces A-B and B-C, and faces D-E and E-F.
The intersection of these zones produces the faces a-d, d-b, b-e, and e-c. Faces produced in the region where the two cell zones overlap (d-b, b-e, and e-c) are grouped to form an interior or coupled wall zone (depending on the types of the adjacent cell zones), while the remaining face (a-d) forms a wall zone.

To compute the flux across the interface into cell IV, face D-E is ignored and instead faces d-b and b-e are used to bring information into cell IV from cells I and III.

While the previous discussion described the default treatment of a non-conformal interface, there are several options you can enable to revise the treatment of the fluxes at the interface:

- periodic boundary condition
- periodic repeats
- coupled wall
- matching

These non-conformal interface options are described in the following sections.

5.4.1.1. The Periodic Boundary Condition Option
5.4.1.2. The Periodic Repeats Option
5.4.1.3. The Coupled Wall Option
5.4.1.4. Matching Option
5.4.1.1. The Periodic Boundary Condition Option

Non-conformal interfaces can be used to implement a periodic boundary condition like that described for conformal periodic boundaries (see Periodic Boundary Conditions (p. 332)). The advantage of using a mesh interface is that, unlike the standard periodic boundary condition, the nodes of the two zones do not have to match one-for-one.

The interface zones that utilize the periodic boundary condition option (Figure 5.29: Non-Conformal Periodic Boundary Condition (Translational) (p. 151) and Figure 5.30: Non-Conformal Periodic Boundary Condition (Rotational) (p. 152)) are coupled in the manner described in the previous section, except that the zones do not overlap (that is, the zones are not spatially coincident at any point). In order to generate the new faces that will be used to compute the fluxes across the interface, the nodes of the first zone are either translated or rotated (about a given axis) onto the other zone. The distance/angle that the nodes are translated/rotated is called the “periodic offset”. The new faces will be defined between all of the combined nodes, and then applied to each of the original zones.

Figure 5.29: Non-Conformal Periodic Boundary Condition (Translational)
5.4.1.2. The Periodic Repeats Option

The periodic repeats option is appropriate when each of the interface zones is adjacent to a non-conformal periodic interface or a pair of conformal periodic zones (see Figure 5.31: Translational Non-Conformal Interface with the Periodic Repeats Option (p. 153) and Figure 5.32: Rotational Non-Conformal Interface with the Periodic Repeats Option (p. 154)). The periodic repeats option takes into account the repeating nature of the flow solutions in the two cell zones in the following manner. Wherever the interface zones overlap (that is, wherever interface zone 1 and 2 are spatially coincident), the fluxes on either side of the interface are coupled in the usual way. The portion of interface zone 1 that does not overlap is coupled to the non-overlapping portion of interface zone 2, by translating or rotating the fluxes by the periodic offset. This is similar to the treatment of non-conformal periodic boundary conditions. The periodic repeats option is typically used in conjunction with the sliding mesh model when simulating the interface between a rotor and stator.
Figure 5.31: Translational Non-Conformal Interface with the Periodic Repeats Option
5.4.1.3. The Coupled Wall Option

As described previously, the typical function of non-conformal interfaces is to couple fluid zones, so as to permit fluid flow to pass from one mesh interface to the other. Another available option is to create a coupled wall boundary at the interface. In such a case, fluid flow would not pass across the interface, as the interface is acting as a wall zone. Coupled wall heat transfer, on the other hand, would be permitted. Such an interface is required if one or both of the cell zones is a solid. It is also allowable if both of the cell zones are fluids; for example, you can model a thin wall or baffle separating the two fluid zones. Figure 5.33: Non-Conformal Coupled Wall Interfaces (p. 155) illustrates coupled walls with both solid and fluid zones.

Note that coupled walls can also make use of the periodic repeats option. That is, both options can be invoked simultaneously. For details see Using a Non-Conformal Mesh in ANSYS Fluent (p. 159).
5.4.1.4. Matching Option

When two interface zones do not match well (which could result from different mesh topologies, geometric misalignment, or the existence of large gaps), wall zones will be created on the interface. If, in such cases, you want to have only interior zones generated on the interface, it is best to use a matching interface. If the interface zones cover each other completely, and no wall zones are expected to be created on the mesh interface, it is recommended that you select the Matching option.

Note

The Matching option is also compatible with the periodic boundary condition option.

Figure 5.34: Matching Non-Conformal Wall Interfaces (p. 156) below shows two interface zones that do not match up well in the center -- the interface zone on the right has an inverted spike. Even with such a large mismatch, the Matching option still enables you to create an interface with only the interior zone.
When the **Matching** option is selected, ANSYS Fluent checks if one interface zone sits on top of the other and displays messages if there is an overlap of cell zones that are connected through a mesh interface (therefore making the interface invalid for use). Since the severity of zone overlap is different for matching interfaces and non-matching interfaces, ANSYS Fluent displays different messages accordingly.

For example, for non-matching interfaces:

*Info:* Interface zones overlap for mesh interface (interface-name). This could adversely affect your solution.

Likewise, for matching interfaces:

*Warning:* Interface zone overlaps for mesh interface (interface-name). This could generate left-handed faces on the interface and make it invalid for use.

### 5.4.2. Non-Conformal Interface Algorithm

In the current version of ANSYS Fluent, non-conformal interface calculations are handled using a virtual polygon approach, which stores the area vector and centroid of the polygon faces. This approach does not involve node movement and cells are not necessarily water-tight cells. Hence gradients are corrected to take into account the missing face area. Note that in transient cases, the stationary non-conformal interfaces will be automatically preserved by ANSYS Fluent during mesh update.
Previous versions of Fluent (6.1 or earlier) used a triangular face approach, which triangulated the polygon intersection faces and stored triangular faces. This approach involved node movement and water-tight cells, and was not as stable as the current virtual polygon approach. Note that case files in which the interface was set up using Fluent 6.1 or earlier can be read and run normally in the current version of ANSYS Fluent, which will use the virtual polygon approach rather than the triangular face approach.

It is possible that distorted meshes may be produced during sliding mesh calculations, generating what are called “left-handed” faces. You cannot obtain a flow solution until all of the faces are “right handed”, and so ANSYS Fluent corrects the left handedness of these faces automatically. In extreme cases, the left-handed faces cannot be fully corrected and are deleted automatically, so that the solution does not diverge.

Left-handed cells can also be created for the geometries that contain sharp edges and corners, which may affect the final solution. For such geometries, you should first separate the zones and then create the interfaces separately to get the better solution.

The additional input of the angle/translation vector at the angle/translation-vector prompt in the console may be required to recreate face-periodic interfaces. Also, with the current mesh interface algorithm in parallel, there is no need for encapsulation.

### 5.4.3. Requirements and Limitations of Non-Conformal Meshes

This section describes the requirements and limitations of non-conformal meshes:

- The mesh interface can be of any shape (including a non-planar surface, in 3D), provided that the two interface boundaries are based on the same geometry. If there are sharp features (for example, 90-degree angles) or curvature in the mesh, it is especially important that both sides of the interface closely follow that feature.

For example, consider the case of two concentric circles that define two fluid zones with a circular, non-conformal interface between them, as shown in Figure 5.35: A Circular Non-Conformal Interface (p. 158). Because the node spacing on the interface edge of the outer fluid zone is coarse compared to the radius of curvature, the interface does not closely follow the feature (in this case, the circular edge.)

---

**Important**

The maximum tolerance between two interfaces should not be larger than their adjacent cell size at that location. That is no cell should be completely enclosed between two interfaces.
Figure 5.35: A Circular Non-Conformal Interface

- If you create a single mesh with multiple cell zones separated by a non-conformal boundary, you must be sure that each cell zone has a distinct face zone on the non-conformal boundary.

The face zones for two adjacent cell zones will have the same position and shape, but one will correspond to one cell zone and one to the other. It is also possible to create a separate mesh file for each of the cell zones, and then merge them as described in Reading Multiple Mesh/Case/Data Files (p. 143).

- All periodic zones must be correctly oriented (either rotational or translational) before you create the non-conformal interface.

- In order for the periodic boundary condition option or periodic repeats option to be valid, the edges of the second interface zone must be offset from the corresponding edges of the first interface zone by a uniform amount (either a uniform translational displacement or a uniform rotation angle). This is not true for non-conformal interfaces in general.

The periodic boundary condition option has the additional requirement that the angle associated with a rotational periodic must be able to divide 360 without remainder.

- The periodic repeats option requires that some portion of the two interface zones must overlap (that is, be spatially coincident).

- The periodic repeats option requires that the non-overlapping portions of the interface zones must have identical shape and dimensions. If the interface is part of a sliding mesh, you must define the mesh motion such that this criterion is met at all times.

- Note that for 3D cases, you cannot have more than one pair of conformal periodic zones adjacent to each of the interface zones.

- You must not have a single non-conformal interface where part of the interface is made up of a coupled two-sided wall, while another part is not coupled (that is, the normal interface treatment). In such cases, you must break the interface up into two interfaces: one that is a coupled interface, and the other that is a standard fluid-fluid interface. See Using a Non-Conformal Mesh in ANSYS Fluent (p. 159) for information about creating coupled interfaces.
• For simulations that involve the Fluent, Mechanical, and Meshing applications, meshing problems can arise in instances where there are multiple regions and contacts between them. In Fluent, a zone can only exist in a single contact region. The Mechanical and Meshing applications both use a different approach concerning contact regions when compared to Fluent.

5.4.4. Using a Non-Conformal Mesh in ANSYS Fluent

If your multiple-zone mesh includes non-conformal boundaries, check if the mesh meets all the requirements (listed in Requirements and Limitations of Non-Conformal Meshes (p. 157)). This ensures that ANSYS Fluent can obtain a solution on the mesh. Then do the following:

1. Read the mesh into ANSYS Fluent. If you have multiple mesh files that have not yet been merged, first follow the instructions in Reading Multiple Mesh/Case/Data Files (p. 143) to merge them into a single mesh.

2. After reading in the mesh, change the type of each pair of zones that comprises the non-conformal boundary to interface (as described in Changing Cell and Boundary Zone Types (p. 203)).

3. Define the non-conformal mesh interfaces in the Create/Edit Mesh Interfaces Dialog Box (p. 2172) (Figure 5.36: The Create/Edit Mesh Interfaces Dialog Box (p. 159)).

Figure 5.36: The Create/Edit Mesh Interfaces Dialog Box
a. Enter a name for the interface in the **Mesh Interface** text-entry box.

b. Specify the two interface zones that comprise the mesh interface by selecting one or more zones in the **Interface Zone 1** list and one or more zones in the **Interface Zone 2** list.

---

**Important**

If one of your interface zones is much smaller than the other, you should specify the smaller zone as **Interface Zone 1** to improve the accuracy of the intersection calculation.

---

c. Enable the desired **Interface Options**, if appropriate. There are several options:

- Enable **Periodic Boundary Condition** to create a non-conformal periodic boundary condition interface.
  - Select either **Translational** or **Rotational** as the periodic boundary condition **Type** to define the type of periodicity.
  - Retain the enabled default setting of **Auto Compute Offset** if you want ANSYS Fluent to automatically compute the offset. After creating the interface, the offsets will be displayed in these fields. The fields will be uneditable when the **Auto Compute Offset** is enabled.
  - Disable **Auto Compute Offset** if you decide that you do not want ANSYS Fluent to find the offset. In this case, you will have to provide the offset coordinates or angle in the required fields, depending on whether **Translational** or **Rotational** periodicity is selected.

---

**Important**

Auto computation means that the rotational angle or the translational offset will be automatically calculated and used while creating a non-conformal periodic boundary condition interface. However, it still relies on the **Rotational Axis Origin** and the **Rotational Axis Direction** that was entered for the cell zone in the cell zone condition dialog box (for example, the **Fluid** dialog box). Therefore, before proceeding with the creation of the non-conformal periodic boundary condition interface, you must to correctly enter the rotational axis for the corresponding cell zone.

Note that auto computation of the non-conformal periodic boundary condition offset does not mean that the **Rotational Axis Origin** and **Rotational Axis Direction** are also detected automatically and updated. It is still your responsibility to set these values correctly.

---

**Important**

The **Periodic Boundary Condition** option is only valid when a single zone is selected in each of the **Interface Zone 1** and the **Interface Zone 2** selection lists.
• Enable **Periodic Repeats** when each of the two cell zones has a single pair of conformal or non-conformal periodics adjacent to the interface (see Figure 5.31: Translational Non-Conformal Interface with the Periodic Repeats Option (p. 153)). This option is typically used in conjunction with the sliding mesh model, when simulating the interface between a rotor and stator.

**Important**

The **Periodic Repeats** option is only valid when a single zone is selected in each of the **Interface Zone 1** and the **Interface Zone 2** selection lists.

• Enable **Coupled Wall** if you would like to model a thermally coupled wall between two fluid zones that share a non-conformal interface.

**Important**

Note that the interface between a solid zone and a fluid zone is coupled by default. Therefore, no action is required in the **Create/Edit Mesh Interfaces** dialog box to set up such interfaces.

• Enable the **Matching** option if only interface interior zones should be created, that is, the interface boundary zones should be empty because the interface zones on both sides are aligned. With the **Matching** option, even interface zones that are not perfectly aligned are treated as if they would be, however, if the discrepancy between the interface zones on both sides exceeds default thresholds, then warning messages will be displayed. Note that the **Matching** option is also compatible with periodic boundary conditions. See **Matching Option** (p. 155) for more information about the recommended uses of this option.

d. Click **Create** to create a new mesh interface. For all types of interfaces, ANSYS Fluent will create boundary zones for the interface (for example, **wall-9**, **wall-10**), which will appear under **Boundary Zone 1** and **Boundary Zone 2**. If you have enabled the **Coupled** option, ANSYS Fluent will also create wall interface zones (for example, **wall-4**, **wall-4-shadow**), which will appear under **Interface Wall Zone 1** and **Interface Wall Zone 2**.

e. If the two interface zones did not overlap entirely, check the boundary zone type of the zone(s) created for the non-overlapping portion(s) of the boundary. If the zone type is not correct, you can use the **Boundary Conditions Task Page** (p. 2102) to change it.

f. If you have any **Coupled Wall** type interfaces, define boundary conditions (if relevant) by updating the interface wall zones using the **Boundary Conditions** task page.

**Boundary Conditions**

If you create an incorrect mesh interface, you can select it in the **Mesh Interface** selection list and click the **Delete** button to delete it. Any boundary zones or wall interface zones that were created when the interface was created will also be deleted. You may then proceed with the problem setup as usual.

You can click the **Draw** button to display interface zones or mesh interfaces in the graphics window. Note that you can only select and display interface zones from **Interface Zone 1** or **Interface Zone 2** prior to defining any **Mesh Interfaces**. After a **Mesh Interface** is defined, you can select the ap-
propriate mesh interface and click the Draw button to display the zones under Interface Zone 1 and Interface Zone 2 together as defined by the Mesh Interface. This is particularly useful if you want to check the location of the interface zones prior to setting up a mesh interface.

5.5. Checking the Mesh

The mesh checking capability in ANSYS Fluent examines various aspects of the mesh, including the mesh topology, periodic boundaries, simplex counters, and (for axisymmetric cases) node position with respect to the \( x \) axis, and provides a mesh check report with details about domain extents, statistics related to cell volume and face area, and information about any problems associated with the mesh. You can check the mesh by clicking the Check button in the General task page.

**Important**

It is generally a good idea to check your mesh right after reading it into Fluent, in order to detect any mesh trouble before you get started with the problem setup.

The mesh check examines the topological information, beginning with the number of faces and nodes per cell. A triangular cell (2D) should have 3 faces and 3 nodes, a tetrahedral cell (3D) should have 4 faces and 4 nodes, a quadrilateral cell (2D) should have 4 faces and 4 nodes, and a hexahedral cell (3D) should have 6 faces and 8 nodes. Polyhedral cells (3D) will have an arbitrary number of faces and nodes.

Next, the face handedness and face node order for each zone is checked. The zones should contain all right-handed faces, and all faces should have the correct node order.

The last topological verification is checking the element-type consistency. If a mesh does not contain mixed elements (quadrilaterals and triangles or hexahedra and tetrahedra), ANSYS Fluent will determine that it does not need to keep track of the element types. By doing so, it can eliminate some unnecessary work.

For axisymmetric cases, the number of nodes below the \( x \) axis is listed. Nodes below the \( x \) axis are forbidden for axisymmetric cases, since the axisymmetric cell volumes are created by rotating the 2D cell volume about the \( x \) axis; therefore nodes below the \( x \) axis would create negative volumes.

For solution domains with rotationally periodic boundaries, the minimum, maximum, average, and prescribed periodic angles are computed. A common mistake is to specify the angle incorrectly. For domains with translationally periodic boundaries, the boundary information is checked to ensure that the boundaries are truly periodic.

Finally, the simplex counters are verified. The actual numbers of nodes, faces, and cells that Fluent has constructed are compared to the values specified in the corresponding header declarations in the mesh file. Any discrepancies are reported.

5.5.1. Mesh Check Report

5.5.2. Repairing Meshes

5.5.1. Mesh Check Report

When you click the Check button in the General task page, a mesh check report will be displayed in the console. The following is a sample of a successful output:
Mesh Check

Domain Extents:
- x-coordinate: min (m) = -4.000000e-002, max (m) = 2.550000e-001
- y-coordinate: min (m) = 0.000000e+000, max (m) = 2.500000e-002

Volume statistics:
- minimum volume (m3): 2.463287e-009
- maximum volume (m3): 4.508038e-007
- total volume (m3): 4.190433e-004

Face area statistics:
- minimum face area (m2): 4.199967e-004
- maximum face area (m2): 2.434403e-003

Checking mesh.......................
Done.

The mesh check report begins by listing the domain extents. The domain extents include the minimum and maximum x, y, and z coordinates in meters.

Then the volume statistics are provided, including the minimum, maximum, and total cell volume in m³. A negative value for the minimum volume indicates that one or more cells have improper connectivity. Cells with a negative volume can often be identified using the Iso-Value Adaption dialog box to mark them for adaption and view them in the graphics window. For more information on creating and viewing iso-value adaption registers, see Isovalue Adaption (p. 1555). You must eliminate these negative volumes before continuing the flow solution process.

Next, the mesh report lists the face area statistics, including the minimum and maximum areas in m². A value of 0 for the minimum face area indicates that one or more cells have degenerated. As with negative volume cells, you must eliminate such faces. It is also recommended to correct cells that have nonzero face areas, if the values are very small.

Besides the information about the domain extents and statistics, the mesh check report will also display warnings based on the results of the checks previously described. You can specify that the mesh check report displays more detailed information about the various checks and the mesh failures, by using the following text command prior to performing the mesh check:

```
mesh → check-verbosity
```

You will then be prompted to enter the level of verbosity for the mesh check report. The possible levels include:

- **0**
  This is the default level, and only notifies you that checks are being performed (for example, Checking mesh...). The report will look like the previous example; while warnings will be displayed below the domain extents and statistics, the names of the individual checks will not be listed as they are conducted.

- **1**
  This level lists the individual checks as they are performed (for example, Checking right-handed cells). Any warnings that result will be displayed immediately below the check that produced it.

- **2**
  This level provides the maximum information about the mesh check. The report will list the individual checks as they are performed (for example, Checking right-handed cells); any warnings that result
will be displayed immediately below the check that produced it. Additional details about the check failure will also be displayed, such as the location of the problem or the affected cells.

5.5.2. Repairing Meshes

If the mesh check report indicates a mesh problem or if you receive warnings, you can investigate the extent of the problem by printing the poor element statistics in the console. This can be accomplished using the **Report Poor Quality Elements** button, located at the bottom of the **Solution Methods** task page (Figure 5.37: The Solution Methods Task Page). Note that this button is only available when the mesh has poor quality elements. For more information about the **Report Poor Quality Elements** feature, see Robustness on Meshes of Poor Quality (p. 1535).

**Figure 5.37: The Solution Methods Task Page**

Alternatively, you can print the poor element statistics via the following text command:

```
mesh → repair-improve → report-poor-elements
```

You can also visualize the invalid and poor elements: first, mark them by using the **Mesh...** and **Mark Poor Elements** selections from the **Iso-Values of** drop-down lists of the **Iso-Value Adaption** dialog box (see Performing Isovalue Adaption (p. 1555) for further details). Then, display them in the graphics window using the **Manage Adaption Registers** dialog box, as described in Manipulating Adaption Registers (p. 1564). Similarly, you can display them using the **Contours** dialog box, by selecting **Mesh...** and **Mark Poor Elements** from the **Contours of** drop-down lists. In either case, a value of 1 is assigned
to the cells that are identified as invalid or poor, as well as the cells that are adjacent to the face of an invalid or poor cell, and a value of 0 is assigned to all other cells.

The mesh check report will indicate if the mesh has problems that must be repaired, such as left-handed faces and/or faces that have the wrong node order. The simplest way to attempt to correct your mesh problems is to use the following text command:

```
mesh → repair-improve → repair
```

The mesh/repair-improve/repair text command will attempt to correct a number of problems identified by the mesh check, including cells that have:

- the wrong node order
- the wrong face handedness or that are not convex
- faces that are small or nonexistent
- very poor quality (see Mesh Quality (p. 129) for additional details)

Note that by default, the repair text command will only adjust the positions of interior nodes. If you want to also modify the nodes on the boundaries of the mesh, use the following text command before you repair the mesh:

```
mesh → repair-improve → allow-repair-at-boundaries
```

The repair text command may convert degenerate cells into polyhedra, based on skewness criteria (for more information on how cells are converted, see Converting Skewed Cells to Polyhedra (p. 173)). If you want to ensure that there are no polyhedra in the repaired mesh (for example, if you if plan on performing mesh adaption), you must disable such conversions using the following text command before you repair the mesh:

```
mesh → repair-improve → include-local-polyhedra-conversion-in-repair
```

If you would like to only attempt to improve the poor quality cells, you can use the following text command:

```
mesh → repair-improve → improve-quality
```

You can use the improve-quality text command multiple times, until the mesh is improved to your satisfaction. For greater control over the degree to which the mesh is improved, you can perform quality-based smoothing (as described in Quality-Based Smoothing (p. 1573)).

It should be noted that both the repair and the improve-quality text commands can be CPU intensive, if there are a large number of poor quality cells in the mesh. If you are not as concerned about cell quality, you can attempt to fix only the left-handed faces and faces with the wrong node order. Begin by repairing the node order with the following text command:

```
mesh → repair-improve → repair-face-node-order
```

Because the left-handed faces may be a result of improper face node order, the previous text command may resolve both issues at the same time. Be sure to perform another mesh check after entering the repair-face-node-order command, to see if the mesh has been fully repaired.
If at any point the mesh check reveals that the mesh contains left-handed faces without any node order issues, you can attempt to repair the face handedness by modifying the cell centroids with the following text command:

```
mesh → repair-improve → repair-face-handedness
```

Once again, perform a mesh check to see if the text command was successful. The `repair-face-handedness` text command is most effective for cells with high aspect ratios.

If the mesh check report includes a warning message such as

```
WARNING: node on face thread 2 has multiple shadows.
```

it indicates the existence of duplicate shadow nodes. This error occurs only in meshes with periodic-type walls. You can repair such a mesh using the following text command:

```
mesh → repair-improve → repair-periodic
```

If the interface is rotational periodic, you will be prompted for the rotation angle.

### 5.6. Reporting Mesh Statistics

There are several methods for reporting information about the mesh after it has been read into ANSYS Fluent. You can report the amount of memory used by the current problem, the mesh size, and statistics about the mesh partitions. Zone-by-zone counts of cells and faces can also be reported.

Information about mesh statistics is provided in the following sections:
- **5.6.1. Mesh Size**
- **5.6.2. Memory Usage**
- **5.6.3. Mesh Zone Information**
- **5.6.4. Partition Statistics**

#### 5.6.1. Mesh Size

You can print out the numbers of nodes, faces, cells, and partitions in the mesh by selecting the `Mesh/Info/Size` menu item.

```
Mesh → Info → Size
```

A partition is a piece of a mesh that has been segregated for parallel processing (see Parallel Processing (p. 1833)).

A sample of the resulting output follows:

```
Mesh Size

Level Cells  Faces  Nodes  Partitions
0      7917  12247  4468       1

2 cell zones, 11 face zones.
```

If you are interested in how the cells and faces are divided among the different zones, you can use the `Mesh/Info/Zones` menu item, as described in Mesh Zone Information (p. 168).

If you are using the density-based coupled explicit solver, the mesh information will be printed for each grid level. The grid levels result from creating coarse grid levels for the FAS multigrid convergence ac-
celeration (see Full-Approximation Storage (FAS) Multigrid in the Theory Guide). A sample of the resulting output is shown below:

<table>
<thead>

2 cell zones, 11 face zones.

### 5.6.2. Memory Usage

During an ANSYS Fluent session you may want to check the amount of memory used and allocated in the present analysis. ANSYS Fluent has a feature that will report the following information: the numbers of nodes, faces, cells, edges, and object pointers (generic pointers for various mesh and graphics utilities) that are used and allocated; the amount of array memory (scratch memory used for surfaces) used and allocated; and the amount of memory used by the solver process.

You can obtain this information by selecting the **Mesh/Info/Memory Usage** menu item.

**Mesh → Info → Memory Usage**

The memory information will be different for Linux and Windows systems.

#### 5.6.2.1. Linux Systems

On Linux systems, note the following definitions related to process memory information:

- Process static memory is essentially the size of the code itself.
- Process dynamic memory is the allocated heap memory used to store the mesh and solution variables.
- Process total memory is the sum of static and dynamic memory.

#### 5.6.2.2. Windows Systems

On Windows systems, note the following definitions related to process memory information:

- Process physical memory is the allocated heap memory currently resident in RAM.
- Process virtual memory is the allocated heap memory currently swapped to the Windows system page file.
- Process total memory is the sum of physical and virtual memory.

Note the following:

- The memory information does not include the static (code) memory.
- In the serial version of ANSYS Fluent, the heap memory value includes storage for the solver (mesh and solution variables), and Cortex (GUI and graphics memory), since Cortex and the solver are contained in the same process.
• In the parallel version, Cortex runs in its own process, so the heap memory value includes storage for the mesh and solution variables only.

On Windows systems, you can also get more information on the ANSYS Fluent process (or processes) by using the Task Manager (see your Windows documentation for details). For the serial version, the process image name will be something like fl1400s.exe. For the parallel version, examples of process image names are as follows: cx1400.exe (Cortex) and fl1400.exe (solver host).

5.6.3. Mesh Zone Information

You can print information in the console about the nodes, faces, and cells in each zone using the Mesh/Info/Zones menu item.

Mesh → Info → Zones

The mesh zone information includes the total number of nodes and, for each face and cell zone, the number of faces or cells, the cell (and, in 3D, face) type (triangular, quadrilateral, etc.), the boundary condition type, and the zone ID. Sample output is shown below:

Zone sizes on domain 1:
21280 hexahedral cells, zone 4.
532 quadrilateral velocity-inlet faces, zone 1.
532 quadrilateral pressure-outlet faces, zone 2.
1040 quadrilateral symmetry faces, zone 3.
1040 quadrilateral symmetry faces, zone 7.
61708 quadrilateral interior faces, zone 5.
1120 quadrilateral wall faces, zone 6.
23493 nodes.

5.6.4. Partition Statistics

You can print mesh partition statistics in the console by selecting the Mesh/Info/Partitions menu item.

Mesh → Info → Partitions

The statistics include the numbers of cells, faces, interfaces, and neighbors of each partition. See Interpreting Partition Statistics (p. 1875) for further details, including sample output.

5.7. Converting the Mesh to a Polyhedral Mesh

Since the ANSYS Fluent solver is face based, it supports polyhedral cells. The advantages that polyhedral meshes have shown over some of the tetrahedral or hybrid meshes is the lower overall cell count, almost 3-5 times lower for unstructured meshes than the original cell count. Currently, there are three options in ANSYS Fluent that allow you to convert your non-polyhedral cells to a polyhedra:

• Converting the entire domain into polyhedral cells (applicable only for meshes that contain tetrahedral and/or wedge cells).

• Converting skewed tetrahedral cells to polyhedral cells.

• Converting cells with hanging nodes/edges to polyhedral cells.

Information about polyhedral mesh conversion is provided in the following sections:

5.7.1. Converting the Domain to a Polyhedra
5.7.2. Converting Skewed Cells to Polyhedra
5.7.3. Converting Cells with Hanging Nodes / Edges to Polyhedra
5.7.1. Converting the Domain to a Polyhedra

Conversion of a mesh to polyhedra only applies to 3D meshes that contain tetrahedral and/or wedge cells.

To begin the conversion process, ANSYS Fluent automatically decomposes each non-hexahedral cell into multiple sub-volumes called "duals" (the shaded regions seen in the 2D example in Figure 5.38: Connection of Edge Centroids with Face Centroids (p. 169)). Each dual is associated with one of the original nodes of the cell. These duals are then agglomerated into polyhedral cells around the original nodes. Therefore, the collection of duals from all cells sharing a particular node makes up each polyhedral cell (see Figure 5.39: A Polyhedral Cell (p. 170)). The node that is now within the polyhedral cell is no longer needed and is removed.

To better understand how duals are formed, you can consider the straightforward case of a tetrahedral mesh. Each of the cells are decomposed in the following manner: first, new edges are created on each face between the face centroid and the centroids of the edges of that face. Then, new faces are created within the cell by connecting the cell centroid to the new edges on each face. These interior faces establish the boundaries between the duals of a cell, and divide the cell into 4 sub-volumes. These dividing faces may be adjusted and merged with neighboring faces during the agglomeration process, in order to minimize the number of faces on the resultant polyhedral cell.

Figure 5.38: Connection of Edge Centroids with Face Centroids
**Important**

Hexahedral cells are not converted to polyhedra when the domain is converted, except when they border non-hexahedral cells. When the neighboring cell is reconfigured as polyhedra, the shared face of the hexahedral cell is decomposed into multiple faces as well, resulting in a polyhedral cell. In such a case the shape of the original hexahedral cell is preserved (that is the overall dimensions of the cell stay the same), but the converted cell has more than the original 6 faces (see Figure 5.40: A Converted Polyhedral Cell with Preserved Hexahedral Cell Shape (p. 170)).

Conversion proceeds in a slightly different manner in boundary layers that are modeled using thin wedge cells. These cells are decomposed in the plane of the boundary surface, but not in the direction normal to the surface. The resulting polyhedra will therefore preserve the thickness of the original wedge cells (Figure 5.41: Treatment of Wedge Boundary Layers (p. 171)). In most cases, the cell count in the new polyhedral boundary layer will be lower than the original boundary layer.
To convert the entire domain of your mesh, use the **Mesh/Polyhedra/Convert Domain** menu.

Mesh → Polyhedra → Convert Domain

The following is an example of the resulting message printed in the console:

Setup conversion to polyhedra.
Converting domain to polyhedra...

Creating polyhedra zones.
Processing face zones............
Processing cell zones...
Building polyhedra mesh............... 
Optimizing polyhedra mesh.....

>> Reordering domain using Reverse Cuthill-McKee method:
zones, cells, faces, done.
Bandwidth reduction = 1796/247 = 7.27
Done.

**Figure 5.42: The Original Tetrahedral Mesh** (p. 171), the original tetrahedral mesh of a section of a manifold, is compared to **Figure 5.43: The Converted Polyhedral Mesh** (p. 172), which is the resulting mesh after the entire domain is converted to a polyhedra.

**Figure 5.43: The Converted Polyhedral Mesh**
Note that by default, the surfaces (that is, manifold zones of type `interior`) will be lost during the conversion to polyhedra. If you would like to preserve any of these zones (in order to utilize them for postprocessing, for example), use the following text command prior to the conversion:

```
mesh → polyhedra → options → preserve-interior-zones
```

You will be prompted to enter a string of characters, and only those interior surfaces with a name that includes the string you specify will be preserved.

### 5.7.1.1. Limitations

Some limitations you will find with polyhedral meshes that you generally do not experience with other cell types include:

- Meshes that already contain polyhedral cells cannot be converted.
- Meshes with hanging nodes/edges will not be converted. This includes meshes that have undergone hanging node adaption (see Hanging Node Adaption in the Theory Guide), as well as CutCell meshes (generated by Workbench or the meshing mode of Fluent, or resulting from the CutCell zone remeshing method in the solution mode of Fluent) and hexcore meshes (generated when using the Hex Core meshing scheme in GAMBIT or the Hexcore menu option in the meshing mode of Fluent).
- The following mesh manipulation tools are not available for polyhedral meshes:
  - `mesh/modify-zones/extrude-face-zone-delta` text command
  - `mesh/modify-zones/extrude-face-zone-para` text command
  - skewness smoothing
  - swapping
- Meshes in which the domain has been converted to polyhedral cells are not eligible for adaption. For more information about adaption, see Adapting the Mesh (p. 1545).
- A mesh that is entirely comprised of polyhedral cells has limitations when it is to be used in a dynamic mesh problem: it cannot undergo dynamic layering, and the only remeshing method available is CutCell zone remeshing. Smoothing is allowed for polyhedral cells, and diffusion-based smoothing is recommended over spring-based smoothing (see Diffusion-Based Smoothing (p. 581) for details). The linearly elastic solid smoothing method is not compatible with polyhedral cells.
• Since polyhedral meshes can have a much higher ratio of nodes to cells than tet or hex meshes, the use of the node-based gradient method may result in a significant increase in memory consumption compared with other gradient methods.

5.7.2. Converting Skewed Cells to Polyhedra

Another method of cell agglomeration is the skewness-based cluster approach. This type of conversion is designed to convert only part of the domain. The objective is to convert only skewed tetrahedral cells above a specified cell equivolume skewness threshold into polyhedra. By converting the highly skewed tetrahedral cells, the quality of the mesh can be improved significantly.

A different algorithm is used for local conversion. This algorithm evaluates each highly skewed tetrahedral cell and all of the surrounding cells, to select an edge on the highly skewed cell that best matches criteria for cell agglomeration. Then all of the cells that share this edge are combined into a polyhedral cell. During the process, the data is interpolated from the original cells to the resultant polyhedra.

5.7.2.1. Limitations

There are certain limitations with this type of conversion:

• The following mesh manipulation tools are not available on polyhedral meshes:
  – the mesh/modify-zones/extrude-face-zone-delta text command
  – the mesh/modify-zones/extrude-face-zone-para text command
  – skewness smoothing
  – swapping will not affect polyhedral cells

• The polyhedral cells that result from the conversion are not eligible for adaption. For more information about adaption, see Adapting the Mesh (p. 1545).

• Only tetrahedral cells are converted, as all other cells are skipped.

• Meshes with hanging nodes / edges will not be converted. This includes meshes that have undergone hanging node adaption (see Hanging Node Adaption in the Theory Guide), as well as CutCell meshes (generated by Workbench or the meshing mode of Fluent, or resulting from the CutCell zone remeshing method in the solution mode of Fluent) and hexcore meshes (generated when using the Hex Core meshing scheme in GAMBIT or the Hexcore menu option in the meshing mode of Fluent). Note that if the mesh is a CutCell / hexcore mesh in which the transitional cells have been converted to polyhedra, then it does not have hanging nodes / edges and can therefore be converted.

• The polyhedral cells that result from this conversion have the following limitations with regard to the update methods available for dynamic mesh problems:
  – When applying dynamic layering to a cell zone, you cannot have polyhedral cells adjacent to the moving face zone.
  – None of the remeshing methods except for CutCell zone remeshing will modify polyhedral cells.

Note that smoothing is allowed for polyhedral cells, and diffusion-based smoothing is recommended over spring-based smoothing (see Diffusion-Based Smoothing (p. 581) for details). The linearly elastic solid smoothing method is not compatible with polyhedral cells.
5.7.2.2. Using the Convert Skewed Cells Dialog Box

To convert skewed cells in your domain to polyhedral cells, go to the **Convert Skewed Cells** dialog box.

Mesh → Polyhedra → Convert Skewed Cells...

**Figure 5.44: The Convert Skewed Cells Dialog Box**

1. Select the zone(s) you want to consider for local polyhedra conversion from the **Cell Zones** selection list. After the zone selection is made, the **Current** value of the **Maximum Cell Skewness** and the percentage of **Cells Above Target** are displayed.

2. Specify the maximum allowable cell skewness in the **Target** text-entry box, and press **Enter** to update the **Cells Above Target**.

   **Important**

   The **Cells Above Target (%)** should be only a couple of percentage points, otherwise the conversion will be ineffective due to the high face count.

3. Click the **Convert** button.

   The number of created polyhedra and the resulting maximum cell skewness will be printed in the console.

5.7.3. Converting Cells with Hanging Nodes / Edges to Polyhedra

ANSYS Fluent provides a text command that allows you to convert cells that have hanging nodes / edges into polyhedra. Such a conversion may be done in order to prevent errors associated with interior walls (see Using the **tpoly** Filter to Remove Hanging Nodes/Edges (p. 141)). Each of the converted polyhedra preserve the shape of the original cell (that is, the overall dimensions of each cell stay the same), but the number of faces associated with each cell increases (see Figure 5.40: A Converted Polyhedral Cell with Preserved Hexahedral Cell Shape (p. 170) for an example). Such a conversion may be helpful for CutCell meshes (generated by Workbench or the meshing mode of Fluent, or resulting from the CutCell zone remeshing method in the solution mode of Fluent), as well as hexcore meshes (generated when using the **Hex Core** meshing scheme in GAMBIT or the **Hexcore** menu option in the meshing
mode of Fluent). You could also convert the cells with hanging nodes in a mesh that has undergone adaptation (see Adapting the Mesh (p. 1545)), but you would need to be sure that no further refinement/coarsening of the mesh will be necessary.

To convert the cells with hanging nodes / edges, use the following text command:

```
mesh → polyhedra → convert-hanging-nodes
```

### 5.7.3.1. Limitations

There are certain limitations with this type of conversion:

- The following mesh manipulation tools are not available on polyhedral meshes:
  - the `mesh/modify-zones/extrude-face-zone-delta` text command
  - the `mesh/modify-zones/extrude-face-zone-para` text command
  - skewness smoothing
  - swapping will not affect polyhedral cells

- The polyhedral cells that result from the conversion are not eligible for adaption.

- The polyhedral cells that result from this conversion have the following limitations with regard to the update methods available for dynamic mesh problems:
  - When applying dynamic layering to a cell zone, you cannot have polyhedral cells adjacent to the moving face zone.
  - None of the remeshing methods except for CutCell zone remeshing will modify polyhedral cells.

Note that smoothing is allowed for polyhedral cells, and diffusion-based smoothing is recommended over spring-based smoothing (see Diffusion-Based Smoothing (p. 581) for details). The linearly elastic solid smoothing method is not compatible with polyhedral cells.

### 5.8. Modifying the Mesh

There are several ways in which you can modify or manipulate the mesh after it has been read into ANSYS Fluent. You can scale or translate the mesh, copy, merge, or separate zones, create or slit periodic zones, and fuse boundaries. In addition, you can reorder the cells in the domain to decrease bandwidth. Smoothing and diagonal swapping, which can be used to improve the mesh, are described in Improving the Mesh by Smoothing and Swapping (p. 1572). Methods for partitioning meshes to be used in a parallel solver are discussed in Mesh Partitioning and Load Balancing (p. 1852).

**Important**

Whenever you modify the mesh, you should be sure to save a new case file (and a data file, if data exists). If you have old data files that you would like to be able to read in again, be sure to retain the original case file as well, as the data in the old data files may not correspond to the new case file.

Information about mesh manipulation is provided in the following sections:

5.8.1. Merging Zones
5.8.1. Merging Zones

To simplify the solution process, you may want to merge zones. Merging zones involves combining multiple zones of similar type into a single zone. Setting boundary conditions and postprocessing may be easier after you have merged similar zones.

Zone merging is performed in the Merge Zones Dialog Box (p. 2404) (Figure 5.45: The Merge Zones Dialog Box (p. 176)).

Mesh → Merge...

Figure 5.45: The Merge Zones Dialog Box

5.8.1.1. When to Merge Zones

ANSYS Fluent allows you to merge zones of similar type into a single zone. This is not necessary unless the number of zones becomes prohibitive to efficient setup or postprocessing of the numerical analysis. For example, setting the same boundary condition parameters for a large number of zones can be time-consuming and may introduce inconsistencies. In addition, the postprocessing of the data often involves surfaces generated using the zones. A large number of zones often translates into a large number of surfaces that must be selected for the various display options, such as color contouring. Fortunately, surfaces can also be merged (see Grouping, Renaming, and Deleting Surfaces (p. 1601)), minimizing the negative impact of a large number of zones on postprocessing efficiency.
Although merging zones can be helpful, there may be cases where you will want to retain a larger number of zones. Since the merging process is not fully reversible, a larger number of zones provides more flexibility in imposing boundary conditions. Although a large number of zones can make selection of surfaces for display tedious, it can also provide more choices for rendering the mesh and the flow-field solution. For instance, it can be difficult to render an internal flow-field solution. If the outer domain is composed of several zones, the meshes of subsets of these zones can be plotted along with the solution to provide the relationship between the geometry and solution field. Merging zones may also adversely affect dynamic zones and mesh interfaces.

5.8.1.2. Using the Merge Zones Dialog Box

The procedure for merging multiple zones of the same type into a single zone is as follows:

1. Select the zone type in the Multiple Types list. This list contains all the zone types for which there are multiple zones. When you choose a type from this list, the corresponding zones will appear in the Zones of Type list.

2. Select two or more zones in the Zones of Type list.

3. Click the Merge button to merge the selected zones. Note that if your case file has dynamic zones or mesh interfaces, the Warning dialog box will open before the merge is initiated, allowing you to specify whether you want to delete such zones or interfaces first (see Warning Dialog Box (p. 2405) for details).

Important

Remember to save a new case file (and a data file, if data exists).

5.8.2. Separating Zones

Upon reading a mesh file, ANSYS Fluent automatically performs zone separations in two conditions. If a face zone is attached to multiple cells zones in the preprocessor, the face zone will be separated so that each one is attached to only one cell zone. Furthermore, if you have defined an internal face as a wall type, an additional shadow wall zone will be generated (for example, for a wall named baffle, a shadow wall zone named baffle-shadow will be generated).

There are several methods available in ANSYS Fluent that allow you to manually separate a single face or cell zone into multiple zones of the same type. If your mesh contains a zone that you want to break up into smaller portions, you can make use of these features. For example, if you created a single wall zone when generating the mesh for a duct, but you want to specify different temperatures on specific portions of the wall, you will need to break that wall zone into two or more wall zones. If you plan to solve a problem using the sliding mesh model or multiple reference frames, but you forgot to create different fluid zones for the regions moving at different speeds, you will need to separate the fluid zone into two or more fluid zones.

Important

- After performing any of these separations, you should save a new case file. If data exists, it is automatically assigned to the proper zones when separation occurs, so you should also write a new data file. The old data cannot be read on top of the case file in which the zones have changed.
The maximum number of zones into which you can separate any one face zone or cell zone is 32.

There are four ways to separate face zones and two ways to separate cell zones. The face separation methods will be described first, followed by the cell separation tools. Slitting (decoupling) of periodic zones is discussed in Slitting Periodic Zones (p. 185).

Note that all of the separation methods allow you to report the result of the separation before you commit to performing it.

5.8.2.1. Separating Face Zones

For more information, see the following sections:
- 5.8.2.1.1. Methods for Separating Face Zones
- 5.8.2.1.2. Inputs for Separating Face Zones

5.8.2.1.1. Methods for Separating Face Zones

For geometries with sharp corners, it is often easy to separate face zones based on significant angle. Faces with normal vectors that differ by an angle greater than or equal to the specified significant angle will be placed in different zones. For example, if your mesh consists of a cube, and all 6 sides of the cube are in a single wall zone, you would specify a significant angle of 89°. Since the normal vector for each cube side differs by 90° from the normals of its adjacent sides, each of the 6 sides will be placed in a different wall zone.

If you have a small face zone and would like to put each face in the zone into its own zone, you can do so by separating the faces based on face. Each individual face (triangle, quad, or polygon) will be separated into different zones.

You can also separate face zones based on the marks stored in adaption registers. For example, you can mark cells for adaption based on their location in the domain (region adaption), their boundary closeness (boundary adaption), isovalues of some variable, or any of the other adaption methods discussed in Adapting the Mesh (p. 1545). When you specify which register is to be used for the separation of the face zone, all faces of cells that are marked will be placed into a new face zone. (Use the Manage Adaption Registers Dialog Box (p. 2472) to determine the ID of the register you want to use.)

Finally, you can separate face zones based on contiguous regions. For example, when you use coupled wall boundary conditions you need the faces on the zone to have a consistent orientation. Consistent orientation can only be guaranteed on contiguous regions, so you may need to separate face zones to allow proper boundary condition specification.

5.8.2.1.2. Inputs for Separating Face Zones

To break up a face zone based on angle, face, adaption mark, or region, use the Separate Face Zones Dialog Box (p. 2406) (Figure 5.46: The Separate Face Zones Dialog Box (p. 179)).

Mesh → Separate → Faces...
Figure 5.46: The Separate Face Zones Dialog Box

Important

If you are planning to separate face zones, you should do so before performing any adaptations using the (default) hanging node adaptation method. Face zones that contain hanging nodes cannot be separated.

The steps for separating faces are as follows:

1. Select the separation method (Angle, Face, Mark, or Region) under Options.
2. Specify the face zone to be separated in the Zones list.
3. If you are separating by face or region, skip to the next step. Otherwise, do one of the following:
   - If you are separating faces by angle, specify the significant angle in the Angle field.
   - If you are separating faces by mark, select the adaption register to be used in the Registers list.
4. (optional) To check what the result of the separation will be before you actually separate the face zone, click the Report button. The report will look like the following example:
   
   45 faces in contiguous region 0
   30 faces in contiguous region 1
   11 faces in contiguous region 2
   14 faces in contiguous region 3
   Separates zone 4 into 4 zone(s).

5. To separate the face zone, click the Separate button. A report will be printed in the console like the following example:

   45 faces in contiguous region 0
   30 faces in contiguous region 1
   11 faces in contiguous region 2
   14 faces in contiguous region 3
   Separates zone 4 into 4 zone(s).
   Updating new zone information ...
   created new zone wall-4:001 from wall-4
   created new zone wall-4:002 from wall-4
created new zone wall-4:010 from wall-4
done.

Important

When you separate the face zone by adaption mark, you may sometimes find that a face of a corner cell will be placed in the wrong face zone. You can usually correct this problem by performing an additional separation, based on angle, to move the offending face to a new zone. You can then merge this new zone with the zone in which you want the face to be placed, as described in Merging Zones (p. 176).

5.8.2.2. Separating Cell Zones

For more information, see the following sections:
- 5.8.2.2.1. Methods for Separating Cell Zones
- 5.8.2.2.2. Inputs for Separating Cell Zones

5.8.2.2.1. Methods for Separating Cell Zones

If you have two or more enclosed cell regions sharing internal boundaries (as shown in Figure 5.47: Cell Zone Separation Based on Region (p. 180)), but all of the cells are contained in a single cell zone, you can separate the cells into distinct zones using the separation-by-region method. Note that if the shared internal boundary is of type interior, you must change it to another double-sided face zone type (fan, radiator, etc.) prior to performing the separation.

Figure 5.47: Cell Zone Separation Based on Region

You can also separate cell zones based on the marks stored in adaption registers. You can mark cells for adaption using any of the adaption methods discussed in Adapting the Mesh (p. 1545) (for example, you can mark cells with a certain isovalue range or cells inside or outside a specified region). When you specify which register is to be used for the separation of the cell zone, cells that are marked will be placed into a new cell zone. (Use the Manage Adaption Registers Dialog Box (p. 2472) to determine the ID of the register you want to use.)

5.8.2.2.2. Inputs for Separating Cell Zones

To break up a cell zone based on region or adaption mark, use the Separate Cell Zones Dialog Box (p. 2407) (Figure 5.48: The Separate Cell Zones Dialog Box (p. 181)).

Mesh → Separate → Cells...
If you are planning to separate cell zones, you should do so before performing any adaptations using the (default) hanging node adaption method. Cell zones that contain hanging nodes cannot be separated.

The steps for separating cells are as follows:

1. Select the separation method (Mark or Region) under Options.

2. Specify the cell zone to be separated in the Zones list.

3. If you are separating cells by mark, select the adaption register to be used in the Registers list.

4. (optional) To check what the result of the separation will be before you actually separate the cell zone, click the Report button. The report will look like this:

   Separates zone 14 into two zones, with 1275 and 32 cells.

5. To separate the cell zone, click the Separate button. ANSYS Fluent will print the following information:

   Separates zone 14 into two zones, with 1275 and 32 cells.
   No faces marked on thread, 2
   No faces marked on thread, 3
   No faces marked on thread, 1
   No faces marked on thread, 5
   No faces marked on thread, 7
   No faces marked on thread, 8
   No faces marked on thread, 9
   No faces marked on thread, 61
   Separates zone 62 into two zones, with 1763 and 58 faces.
   All faces marked on thread, 4
   No faces marked on thread, 66
   Moved 32 cells from cell zone 14 to zone 10
   Updating new zone information ...
   created new zone interior-4:010 from interior-4
   created new zone interior-6:009 from interior-6
   created new zone fluid-14:008 from fluid-14
done.

As shown in the example above, separation of a cell zone will often result in the separation of face zones as well. When you separate by mark, faces of cells that are moved to a new zone will be placed...
in a new face zone. When you separate by region, faces of cells that are moved to a new zone will not necessarily be placed in a new face zone.

If you find that any faces are placed incorrectly, see the comment above, at the end of the inputs for face zone separation.

5.8.3. Fusing Face Zones

The face-fusing utility is a convenient feature that can be used to fuse boundaries (and merge duplicate nodes and faces) created by assembling multiple mesh regions. When the domain is divided into subdomains and the mesh is generated separately for each subdomain, you will combine the subdomains into a single file before reading the mesh into Fluent. For details, see Reading Multiple Mesh/Case/Data Files (p. 143). This situation could arise if you generate each block of a multiblock mesh separately and save it to a separate mesh file. Another possible scenario is that you decided, during mesh generation, to save the mesh for each part of a complicated geometry as a separate part file. (Note that the mesh node locations need not be identical at the boundaries where two subdomains meet; see Non-Conformal Meshes (p. 148) for details.)

The Fuse Face Zones dialog box (Figure 5.49: The Fuse Face Zones Dialog Box (p. 182)) allows you to merge the duplicate nodes and delete these artificial internal boundaries.

Mesh → Fuse...

Figure 5.49: The Fuse Face Zones Dialog Box

The boundaries on which the duplicate nodes lie are assigned zone ID numbers (just like any other boundary) when the mesh files are combined, as described in Reading Multiple Mesh/Case/Data Files (p. 143). You need to keep track of the zone ID numbers when you merge or the meshing mode of Fluent reports its progress or, after the complete mesh is read in, display all boundary mesh zones and use the mouse-probe button to determine the zone names (see Controlling the Mouse Button Functions (p. 1654) for information about the mouse button functions). Alternatively, you can specify a name for the fused zone.

5.8.3.1. Inputs for Fusing Face Zones

The steps for fusing face zones are as follows:
1. Select the zones to be fused in the **Zones** list.

**Important**

When using the Fuse Face Zone utility, each of the selected face zones must be fused in its entirety with another face zone having the same connectivity. Partial fusing of face zones is not supported.

2. (Optional) If you would like to specify a name for the fused zone rather than use an automatically generated name (for instance, to preserve the original name of one of the face zones), disable **Use default name for new fused zone** and enter the desired name.

3. Click the **Fuse** button to fuse the selected zones.

If all of the appropriate faces do not get fused using the default **Tolerance**, you should increase it and attempt to fuse the zones again. (This tolerance is the same as the matching tolerance discussed in Creating Conformal Periodic Zones (p. 184).) The **Tolerance** should not exceed 0.5, or you may fuse the wrong nodes.

You can also fuse zones using the `mesh/modify-zones/fuse-face-zones` text command, as shown in the following example.

```
/mesh/modify-zones > fuse-face-zones
()
Zone to fuse(1) [()]  w1.top
Zone to fuse(2) [()]  w3
Zone to fuse(3) [()]  [Enter]
Choose from list (automatic w3 w1.top) or pick your own
Enter the fused zone name: [automatic]  w3

Name of zone 14 is changed into w3.
Fused list of zones successfully.
```

**Important**

Remember to save a new case file (and a data file, if data exists) after fusing faces.

### 5.8.3.1.1. Fusing Zones on Branch Cuts

Meshes imported from structured mesh generators or solvers (such as Fluent 4) can often be O-type or C-type meshes with a reentrant branch cut where coincident duplicate nodes lie on a periodic boundary. Since ANSYS Fluent uses an unstructured mesh representation, there is no reason to retain this artificial internal boundary. (You can preserve these periodic boundaries and the solution algorithm will solve the problem with periodic boundary conditions.)

To fuse this periodic zone with itself, you must first slit the periodic zone, as described in Slitting Periodic Zones (p. 185). This will create two symmetry zones that you can fuse using the procedure above.

Note that if you need to fuse portions of a non-periodic zone with itself, you must use the `mesh/modify-zones/fuse-face-zones` text command.
mesh → modify-zones → fuse-face-zones

This command will prompt you for the name or ID of each zone to be fused. (You will enter the same zone twice.) To change the node tolerance, use the mesh/modify-zones/matching-tolerance text command.

5.8.4. Creating Conformal Periodic Zones

ANSYS Fluent allows you to set up periodic boundaries using either conformal or non-conformal periodic zones. You can assign periodicity to your mesh by coupling a pair of face zones. If the two zones have identical node and face distributions, you can create a conformal periodic zone. If the two zones are not identical at the boundaries within a specified tolerance, then you can create a periodic zone at a non-conformal mesh interface (Non-Conformal Meshes (p. 148)).

**Important**

Remember to save a new case file (and a data file, if data exists) after creating or slitting a periodic boundary.

To create conformal periodic boundaries, you will use the mesh/modify-zones/make-periodic text command.

mesh → modify-zones → make-periodic

You will need to specify the two face zones that will comprise the periodic pair (you can enter their full names or just their IDs), and indicate whether they are rotationally or translationally periodic. The order in which you specify the periodic zone and its matching shadow zone is not significant.

```
/mesh/modify-zones> make-periodic
Periodic zone [{()} 1
Shadow zone [{()} 4
Rotational periodic? (if no, translational) [yes] n
Create periodic zones? [yes] yes
Auto detect translation vector? [yes] yes

computed translation deltas: -2.000000 -2.000000
all 10 faces matched for zones 1 and 4.
zone 4 deleted
created periodic zones.
```

When you create a conformal periodic boundary, Fluent will check to see if the faces on the selected zones “match” (that is, whether or not the nodes on corresponding faces are coincident). The matching tolerance for a face is a fraction of the minimum edge length of the face. If the periodic boundary creation fails, you can change the matching tolerance using the mesh/modify-zones/matching-tolerance text command, but it should not exceed 0.5 or you may match up the periodic zones incorrectly and corrupt the mesh.

mesh → modify-zones → matching-tolerance

For information about creating non-conformal periodic boundaries, see Using a Non-Conformal Mesh in ANSYS Fluent (p. 159).
5.8.5. Slitting Periodic Zones

If you want to decouple the zones in a periodic pair, you can use the `mesh/modify-zones/slit-periodic` text command.

```
mesh → modify-zones → slit-periodic
```

You will specify the periodic zone’s name or ID, and Fluent will decouple the two zones in the pair (the periodic zone and its shadow) and change them to two symmetry zones:

```
/mesh/modify-zones> slit-periodic
Periodic zone [()] periodic-1
Slit periodic zone? [yes] yes
   Slit periodic zone.
```

5.8.6. Slitting Face Zones

The face-zone slitting feature has two uses:

- You can slit a single boundary zone of any double-sided type (that is, any boundary zone that has cells on both sides of it) into two distinct zones.

- You can slit a coupled wall zone into two distinct, uncoupled wall zones.

When you slit a face zone, Fluent will duplicate all faces and nodes, except those nodes that are located at the ends (2D) or edges (3D) of the zone. One set of nodes and faces will belong to one of the resulting boundary zones and the other set will belong to the other zone. The only ill effect of the shared nodes at each end is that you may see some inaccuracies at those points when you graphically display solution data with a slit boundary. (Note that if you adapt the boundary after slitting, you will not be able to fuse the boundaries back together again.)

Before you can slit, you first need to select the zone in the Boundary Condition task page and change the Type to wall. Upon changing the Type to wall, another shadow zone will be created (that is, if the original zone is called `rad-outlet`, another zone called `rad-outlet-shadow` will be created). Then you can apply the `mesh/modify-zones/slit-face-zone` text command on either of the walls (that is, `rad-outlet` or `rad-outlet-shadow`) to separate them into two distinct walls.

**Important**

When a wall and wall-shadow pair is created by slitting a face zone, the wall will inherit the zone id number and face orientation of the original zone. A new zone id number will be created and assigned to the wall-shadow.

For example, the outlet of the radiator in an underhood application is typically of interior type (that is, has cells on both sides). If you know the mass flow rate through this zone (either from other CFD models or from test data) and want to apply it as a boundary condition at the radiator outlet, you first need to slit the radiator outlet. To be able to slit it, select wall from the Type drop-down list in the Boundary Conditions task page for this outlet. It will create a wall and a shadow. Then you can use the TUI command (mesh/modify-zones/slit-face-zone) to slit them. After it is slit, two additional walls will be created, one facing one side of the outlet and another facing the other. Then you can select the appropriate wall and change the Type to mass-flow-inlet and specify the mass flow rate...
using the Mass-Flow Inlet Dialog Box (p. 2124). There is no option of mass-flow-inlet without first slitting it.

**Important**

You should not confuse “slitting” a face zone with “separating” a face zone. When you slit a face zone, additional faces and nodes are created and placed in a new zone. When you separate a face zone, a new zone will be created, but no new faces or nodes are created; the existing faces and nodes are simply redistributed among the zones.

### 5.8.6.1. Inputs for Slitting Face Zones

If you want to slit a face zone, you can use the `mesh/modify-zones/slit-face-zone` text command.

```
mesh → modify-zones → slit-face-zone
```

You will specify the face zone’s name or ID, and Fluent will replace the zone with two zones:

```
/mesh/modify-zones > slit-face-zone

Face zone id/name [] wall-4

  zone 4 deleted
  face zone 4 created
  face zone 10 created
```

**Important**

Remember to save a new case file (and a data file, if data exists) after slitting faces.

### 5.8.7. Orienting Face Zones

The faces of a boundary face zone (which have cells only on one side) are oriented such that the normals are all pointing in one direction. However, for internal face zones (which have cells on both sides), the normals are allowed to point in either direction. To orient them so that they all point in one direction, you can use the following TUI command:

```
mesh → modify-zones → orient-face-zone
```

Having all of the normals oriented in one direction is needed for some boundary condition types. For example, the **fan** boundary condition type determines the flow direction based on its normals. If some of the normals are pointing in one direction and some in the other, the correct flow orientation cannot be determined, which leads to incorrect results.

### 5.8.8. Extruding Face Zones

The ability to extrude a boundary face zone allows you to extend the solution domain without having to exit Fluent. A typical application of the extrusion capability is to extend the solution domain when recirculating flow is impinging on a flow outlet. The current extrusion capability creates prismatic or hexahedral layers based on the shape of the face and normal vectors computed by averaging the face
normals to the face zone’s nodes. You can define the extrusion process by specifying a list of displacements (in SI units) or by specifying a total distance (in SI units) and parametric coordinates.

**Important**

- Note that extrusion is not possible from boundary face zones that have hanging nodes.
- Extruding face zones is not allowed on polygonal face zones.
- Extruding face zones is only allowed in the 3D version of ANSYS Fluent.

### 5.8.8.1. Specifying Extrusion by Displacement Distances

You can specify the extrusion by entering a list of displacement distances (in SI units) using the `mesh/modify-zones/extrude-face-zone-delta` text command.

```
mesh → modify-zones → extrude-face-zone-delta
```

**Note**

This text command is not available in the parallel version of ANSYS Fluent.

You will be prompted for the boundary face zone ID or name and a list of displacement distances.

### 5.8.8.2. Specifying Extrusion by Parametric Coordinates

You can specify the extrusion by specifying a distance (in SI units) and parametric coordinates using the `mesh/modify-zones/extrude-face-zone-para` text command.

```
mesh → modify-zones → extrude-face-zone-para
```

**Note**

This text command is not available in the parallel version of ANSYS Fluent.

You will be prompted for the boundary face zone ID or name, a total distance, and a list of parametric coordinates. The list of parametric coordinates should begin with 0.0 and end with 1.0. For example, the following list of parametric coordinates would create two equally spaced extrusion layers: 0.0, 0.5, 1.0.

### 5.8.9. Replacing, Deleting, Deactivating, and Activating Zones

ANSYS Fluent allows you to append or replace an existing cell zone in the mesh. You can also permanently delete a cell zone and all associated face zones, or temporarily deactivate and activate zones from your ANSYS Fluent case.

#### 5.8.9.1. Replacing Zones

This feature allows you to replace a small region of a computational domain with a new region of different mesh quality. This functionality will be required where you may want to make changes to the
geometry or mesh quality for any part of the domain. This ability of ANSYS Fluent will save you time, since you can modify only the required part of the domain without remeshing the whole domain every time.

The replacement mesh must be prepared in advance, with the following considerations:

- The replacement mesh must contain a single cell zone.
- The cell zone in the replacement mesh must be of the same zone type as the zone that is being replaced.
- If the boundaries of the replacement mesh will form a non-conformal interface with existing zones (that is, zones that are not replaced in the existing mesh), these boundaries should be based on the same geometry as the existing zones. If there are sharp features (for example, 90-degree angles) or curvature in the mesh, it is especially important that both sides of the interface closely follow that feature.
- The replacement cell zone does not need to have the same name as the existing zone being replaced.
- When naming the boundary zones of the replacement cell zone, note that boundary conditions will be automatically transferred from the existing cell zone based on name. All boundaries of the replacement cell zone that have unique names will be assigned the default boundary condition for that zone type.

Replacing a zone is performed using the Replace Cell Zone Dialog Box (p. 2409) (Figure 5.50: The Replace Cell Zone Dialog Box (p. 188)).

**Mesh → Zone → Replace...**

**Figure 5.50: The Replace Cell Zone Dialog Box**

To replace a zone, do the following:

1. Click **Browse...** and select the new or modified mesh containing the cell zone that will replace one of the cell zones in the current mesh.

   *The name of the cell zone in the replacement mesh will be displayed in the Replace with list.*

2. Under **Existing Zones**, select the zone you want to replace.

3. Under **Replace with**, select the zone from the replacement mesh.

4. Enable/Disable **Interpolate Data**, if data already exists. If the replacement cell zone is geometrically different, then **Interpolate Data** can be turned off to prevent data interpolation over the non-matching geometries.
5. Click **Replace** to replace the selected zone.

6. Set up the boundary conditions for any of the boundaries of the replacement mesh that do not share a name with one of the existing boundaries.

### 5.8.9.2. Deleting Zones

To permanently delete zones, select them in the **Delete Cell Zones Dialog Box** (p. 2410) (Figure 5.51: The Delete Cell Zones Dialog Box (p. 189)), and click **Delete**.

**Mesh → Zone → Delete...**

**Figure 5.51: The Delete Cell Zones Dialog Box**

All of the cells, faces, and nodes associated with the cell zone will be deleted. If one of the faces is of type **interior** and borders another cell zone, the face will automatically be changed to a wall and will stay attached to the remaining cell zone.

### 5.8.9.3. Deactivating Zones

To deactivate zones, select them in the **Deactivate Cell Zones Dialog Box** (p. 2410) (Figure 5.52: The Deactivate Cell Zones Dialog Box (p. 189)), and click **Deactivate**.

**Mesh → Zone → Deactivate...**

**Figure 5.52: The Deactivate Cell Zones Dialog Box**
Deactivation will separate all relevant interior face zones (that is, fan, interior, porous-jump, or radiator) into wall and wall-shadow pairs.

**Note**

When you deactivate a zone using the **Deactivate Cell Zones** dialog box, ANSYS Fluent will remove the zone from the mesh and from all relevant solver loops.

To deactivate selected cell zones in parallel

1. Read in the data file, or initialize your solution.
2. Select the zone(s) to be deactivated under **Cell Zones**.
3. Click the **Deactivate** button.

**Important**

If you have neither read in the data file nor initialized the solution prior to clicking the **Deactivate** button, then the selected cell zones will only be marked for deactivation. The zones will not be deactivated until data is read or the solution is initialized.

5.8.9.4. Activating Zones

You can reactivate the zones and recover the last data available for them using the **Activate Cell Zones** Dialog Box (p. 2411) (Figure 5.53: The Activate Cell Zones Dialog Box (p. 190)).

Mesh → Zone → Activate...

**Figure 5.53: The Activate Cell Zones Dialog Box**

**Note**

The **Activate Cell Zones** dialog box will only be populated with zones that were previously deactivated.

After reactivation, you need to make sure that the boundary conditions for the wall and wall-shadow pairs are restored correctly to what you assigned before deactivating the zones. If you plan to reactivate them at a later time, make sure that the face zones that are separated during deactivation are not modified. Adaption, however, is supported.
To activate selected cell zones in parallel

1. Read in the data file, or initialize your solution.
2. Select the zone(s) to be activated under **Cell Zones**.
3. Click the **Activate** button.

---

**Important**

If you have neither read in the data file nor initialized the solution, prior to clicking the **Activate** button, then the selected cell zones will only be *marked* for activation. The zones will not be activated until data is read or the solution is initialized.

---

### 5.8.10. Copying Cell Zones

You can create a copy of a cell zone that is offset from the original either by a translational distance or a rotational angle. Note that in the copied zone, the bounding face zones are all converted to walls, any existing cell data is initialized to a constant value, and non-conformal interfaces and dynamic zones are not copied; otherwise, the model settings are the same as in the original zone.

To copy a zone, use the following text command:

```
mesh → modify-zones → copy-move-cell-zone
```

You will then be prompted to enter the ID of the zone you want to copy, and either the distance for translation in each of the axes or the rotational angle, origin, and axis.

Note that if you want the copied zone to be connected to existing zones, you must either fuse the boundaries (as described in **Fusing Face Zones** (p. 182)) or set up a non-conformal interface (as described in **Using a Non-Conformal Mesh in ANSYS Fluent** (p. 159)).

### 5.8.11. Replacing the Mesh

ANSYS Fluent allows you to replace your mesh, so that you can continue to run your simulation on a new mesh without having to manually copy the case file settings or interpolate the existing data. Replacing the mesh globally may be helpful, for example, if you would like to perform a mesh refinement study with a prepared series of meshes, or if your results indicate that your current mesh is not of sufficient quality. Note that the data interpolation is done automatically during the replacement if data exists (that is, you have initialized the flow field or run a calculation).

Global mesh replacement is performed using the **Mesh/Replace...** menu item, which opens the **Select File** dialog box (Figure 5.54: The Select File Dialog Box (p. 192)).
5.8.11.1. Inputs for Replacing the Mesh

The steps for replacing the mesh using the Select File dialog box (Figure 5.54: The Select File Dialog Box (p. 192)) are as follows:

1. Select the replacement mesh from the appropriate folder.

2. By default, data is interpolated between matching zone pairs (that is, between the zones with the same names in both the current mesh and the replacement mesh). You can enable the Interpolate Data Across Zones option if you want to interpolate data across cell zones when replacing the mesh. This option is appropriate when the matching zone pairs do not have the same interior zone boundaries. Note that global conservation of data is not enforced when the Interpolate Data Across Zones option is enabled, so it should only be used when absolutely necessary. For best data interpolation, the zone boundaries of the replacement mesh should be coincident with those of the current mesh.

3. Click the OK button to replace the mesh.

5.8.11.2. Limitations

The following limitations apply when replacing meshes:

- The boundary conditions of the zones in the current mesh are mapped onto the zones with the same names in the replacement mesh, as described in Reading and Writing Boundary Conditions (p. 56). If your replacement mesh contains zones for which no match is found, these zones will have the default boundary conditions for that zone type.
• The replacement mesh is expected to be an ANSYS Fluent mesh (.msh) file. You can select an ANSYS Fluent case (.cas) file instead, but be aware that only the mesh information will be used and all of the setup information associated with that case file will be ignored.

• If you intend to select an ANSYS Fluent case (.cas) file as the replacement mesh, you must first delete any defined non-conformal mesh interfaces in the case file (as described in Using a Non-Conformal Mesh in ANSYS Fluent (p. 159)).

• You should ensure that the replacement mesh has the same mesh scaling as your current mesh. The data interpolation will not work properly if the meshes are scaled differently.

5.8.12. Managing Adjacent Zones

In some cases you may want to identify and display the face zones which are adjacent to a cell zone. You can do this using the Adjacency dialog box.

Mesh → Adjacency...
Using the **Adjacency** dialog box ([Figure 5.55: The Adjacency Dialog Box (p. 194)](p. 194)) you can also optionally rename zones based on their adjacency or with default names based on zone type. The steps to use the **Adjacency** dialog box are:

1. Open the Adjacency dialog box from **Mesh → Adjacency**...

2. Select a zone under **Cell Zone(s)** to populate the **Adjacent Face Zones** list. You can use the **Cell Zone Types** list box to select or deselect cell zones by type. If the **Multiple Cell Zones** option is disabled, only one cell zone can be selected at a time.

3. Select the face zones you want to display in **Adjacent Face Zones** and click the **Display Face Zones** button. You can use the **Face Zone Types** list box and the **Face Zone Name Pattern** field to select or deselect face zones based on type. To select or deselect zones based on name, specify a **Face Zone Name Pattern** (optionally including wildcards) and click **Match**. For example, if you specify `*inlet*`, all face zones whose names contain `inlet` (for example, `velocity-inlet-5, velocity-inlet-6`) will be selected automatically. If they are all selected already, they will be deselected. If you specify `inlet?`, all face
zones whose names consist of **inlet** followed by a single character will be selected (or deselected, if they are all already selected).

4. Enable **Draw Default Mesh** to open the **Mesh Display** dialog box where you may choose to display mesh zones. These will be displayed permanently while others will be displayed as currently selected in the **Adjacent Face Zones** list. This is useful for finding your way through a new and complex mesh.

5. Enable **Rename Face Zones** if you want to rename or clean up some of the names that may cause confusion. See **Renaming Zones Using the Adjacency Dialog Box** (p. 195) for more information.

### 5.8.12.1. Renaming Zones Using the Adjacency Dialog Box

You can rename selected zones from the Adjacency dialog box after enabling **Rename Face Zones**. The following renaming methods are available:

**Rename by Adjacency**  
appends the name of the cell zone to the type of the adjacent face zone. For example, if **fluid** is selected in the **Cell Zone(s)** and **interior** is selected in the **Adjacent Face Zones** list, then renaming by adjacency produces **interior-fluid**. If the name is already in use, the original zone ID is appended in addition in order to create a unique name. Note that it is best if you avoid using long cell zone names.

**Rename to Default**  
simply appends the original zone ID to the zone type. Enable **Abbreviate Types** to abbreviate the zone type (for example, **vi** for velocity inlet, **int** for interior, **ifc** for interface, and so on).

**Rename by Wildcard**  
performs pattern matching of the selected zone names against the pattern in the **From** text box (with optional wildcards) and replaces a matching substring with the literal string in the **To** text box. Wildcard characters * and ? are interpreted as follows:

- A * at the beginning and/or end of the **From** pattern matches zero or more characters at the beginning and/or end of the zone name which are retained during renaming with the rest of the name replaced by the **To** string.

  A * used anywhere except at the beginning or end of the **From** pattern is not supported and may have unpredictable results.

- A ? matches exactly one character and is considered part of the string to be replaced. Multiple ? characters can be used to match substrings of more than one character.

For all of the renaming methods, you can enable **Exclude Custom Names** to exclude customized names (those that do not conform to a recognized pattern or match any default names) from renaming. This is a protective measure so as not to accidentally destroy your desired naming. Disabling this option will unconditionally rename all selected zones according to the specified renaming method and customized names will be permanently lost.

### 5.8.13. Reordering the Domain and Zones

Reordering the domain can improve the computational performance of the solver by rearranging the nodes, faces, and cells in memory. The **Mesh/Reorder** submenu contains commands for reordering the domain and zones, and also for printing the bandwidth of the present mesh partitions. The domain can be reordered to increase memory access efficiency, and the zones can be reordered for user-interface convenience. The bandwidth provides insight into the distribution of the cells in the zones and in memory.
To reorder the domain, select the **Domain** menu item.

**Mesh → Reorder → Domain**

To reorder the zones, select the **Zones** menu item.

**Mesh → Reorder → Zones**

Finally, you can print the bandwidth of the present mesh partitions by selecting the **Print Bandwidth** menu item. This command prints the semi-bandwidth and maximum cell distance for each mesh partition.

**Mesh → Reorder → Print Bandwidth**

---

**Important**

Remember to save a new case file (and a data file, if data exist) after reordering.

---

### 5.8.13.1. About Reordering

The Reverse Cuthill-McKee algorithm [19] (p. 2557) is used in the reordering process to construct a “level tree” initiated from a “seed cell” in the domain. First a cell (called the seed cell) is selected using the algorithm of Gibbs, Poole, and Stockmeyer [28] (p. 2558). Each cell is then assigned to a level based on its distance from the seed cell. These level assignments form the level tree. In general, the faces and cells are reordered so that neighboring cells are near each other in the zone and in memory. Since most of the computational loops are over faces, you would like the two cells in memory cache at the same time to reduce cache and/or disk swapping—that is, you want the cells near each other in memory to reduce the cost of memory access. The present scheme reorders the faces and cells in the zone, and the nodes, faces, and cells in memory.

You may also choose to reorder the zones. The zones are reordered by first sorting on zone type and then on zone ID. Zone reordering is performed simply for user-interface convenience.

A typical output produced using the domain reordering is shown below:

>> Reordering domain using Reverse Cuthill-McKee method:
   zones, cells, faces, done.
   Bandwidth reduction = 809/21 = 38.52
   Done.

If you print the bandwidth, you will see a report similar to the following:

   Maximum cell distance = 21

The bandwidth is the maximum difference between neighboring cells in the zone—that is, if you numbered each cell in the zone list sequentially and compared the differences between these indices.

---

### 5.8.14. Scaling the Mesh

Internally, ANSYS Fluent stores the computational mesh in meters, the SI unit of length. When mesh information is read, it is assumed that the mesh was generated in units of meters. If your mesh was created using a different unit of length (inches, feet, centimeters, etc.), you must scale the mesh to meters. To do this, you can select from a list of common units to convert the mesh or you can supply your own custom scale factors. Each node coordinate will be multiplied by the corresponding scale factor.
Scaling can also be used to change the physical size of the mesh. For instance, you could stretch the mesh in the \( x \) direction by assigning a scale factor of 2 in the \( x \) direction and 1 in the \( y \) and \( z \) directions. This would double the extent of the mesh in the \( x \) direction. However, you should use anisotropic scaling with caution, since it will change the aspect ratios of the cells in your mesh.

**Important**

- If you plan to scale the mesh in any way, you should do so before you compute the view factors (as part of an S2S radiation problem), initialize the flow, or begin calculations. Any data that exists when you scale the mesh will be invalid.

- It is a good practice to scale the mesh before setting up the case, especially when you plan to create mesh interfaces or shell conduction zones.

You will use the *Scale Mesh Dialog Box* (p. 1890) (Figure 5.56: The Scale Mesh Dialog Box (p. 197)) to scale the mesh from a standard unit of measurement or to apply custom scaling factors.

**General \( \rightarrow \) Scale...**

**Figure 5.56: The Scale Mesh Dialog Box**

![Scale Mesh Dialog Box](image)

### 5.8.14.1. Using the Scale Mesh Dialog Box

The procedure for scaling the mesh is as follows:

1. Use the conversion factors provided by ANSYS Fluent by selecting **Convert Units** in the **Scaling** group box. Then indicate the units used when creating the mesh by selecting the appropriate abbreviation for meters, centimeters, millimeters, inches, or feet from the **Mesh Was Created In** drop-down list. The **Scaling Factors** will automatically be set to the correct values (for example, 0.0254 meters/inch).
If you created your mesh using units other than those in the Mesh Was Created In drop-down list, you can select Specify Scaling Factors and enter values for X, Y, and Z manually in the Scaling Factors group box (for example, the number of meters per yard).

2. Click the Scale button. The Domain Extents will be updated to show the correct range in meters. If you prefer to use your original unit of length during the ANSYS Fluent session, you can follow the procedure described below to change the unit.

### 5.8.14.1.1. Changing the Unit of Length

As mentioned in Step 2. of the previous section, when you scale the mesh you do not change the units; you just convert the original dimensions of your mesh points from your original units to meters by multiplying each node coordinate by the specified Scaling Factors. If you want to work in your original units, instead of in meters, you can make a selection from the View Length Unit In drop-down list. This updates the Domain Extents to show the range in your original units and automatically changes the length unit in the Set Units Dialog Box (p. 1894) (see Customizing Units (p. 110)). Note that this unit will be used for all future inputs of length quantities.

### 5.8.14.1.2. Unscaling the Mesh

If you use the wrong scale factor, accidentally click the Scale button twice, or want to undo the scaling for any other reason, you can click the Unscale button. “Unscaling” simply divides each of the node coordinates by the specified Scale Factors. (Selecting m in the Mesh Was Created In list and clicking on Scale will not unscale the mesh.)

### 5.8.14.1.3. Changing the Physical Size of the Mesh

You can also use the Scale Mesh Dialog Box (p. 1890) to change the physical size of the mesh. For example, if your 2D mesh is 5 feet by 8 feet, and you want to model the same geometry with dimensions twice as big (10 feet by 16 feet), you can enter 2 for X and Y in the Scaling Factors group box and click Scale. The Domain Extents will be updated to show the new range.

### 5.8.15. Translating the Mesh

You can “move” the mesh by applying prescribed offsets to the Cartesian coordinates of all the nodes in the mesh. This would be necessary for a rotating problem if the mesh were set up with the axis of rotation not passing through the origin, or for an axisymmetric problem if the mesh were set up with the axis of rotation not coinciding with the x axis. It is also useful if, for example, you want to move the origin to a particular point on an object (such as the leading edge of a flat plate) to make an XY plot have the desired distances on the x axis.

You can translate mesh points in ANSYS Fluent using the Translate Mesh Dialog Box (p. 2414) (Figure 5.57: The Translate Mesh Dialog Box (p. 199)).

Mesh → Translate...
5.8.15.1. Using the Translate Mesh Dialog Box

The procedure for translating the mesh is as follows:

1. Enter the desired translations in the \( x \), \( y \), and (for 3D) \( z \) directions (that is, the desired delta in the axes) in the \( X \), \( Y \), and \( Z \) text-entry boxes in the Translation Offsets group box. You can specify positive or negative real numbers in the current unit of length.

2. Click the Translate button and redisplay the mesh. The Domain Extents will be updated to display the new extents of the translated mesh. (Note that the Domain Extents are purely informational; you cannot edit them manually.)

5.8.16. Rotating the Mesh

The ability to rotate the mesh is analogous to the ability to translate the mesh in ANSYS Fluent. You can rotate the mesh about the \( x \), \( y \), or (for 3D) \( z \) axis and also specify the rotation origin. This option is useful in the cases where the structural mesh and the CFD mesh are offset by a small angle.

You can rotate the mesh in ANSYS Fluent using the Rotate Mesh Dialog Box (p. 2415) (Figure 5.58: The Rotate Mesh Dialog Box (p. 200)).

Mesh → Rotate...
5.8.16.1. Using the Rotate Mesh Dialog Box

The procedure for rotating the mesh is as follows:

1. Specify the required Rotation Angle for the mesh. You can specify any positive or negative real number in the correct unit of angle.

2. In the Rotation Origin group box, enter X, Y, and (for 3D) Z coordinates to specify a new origin for the axis of rotation.

3. In the Rotation Axis group box, enter values for the X, Y, and (for 3D) Z axes to specify the vector for the axis of rotation.

4. Click the Rotate button and redisplay the mesh.

   The Domain Extents will be updated to display the new extents of the rotated mesh. (Note that the Domain Extents are purely informational; you cannot edit them manually.)
Chapter 6: Cell Zone and Boundary Conditions

This chapter describes the cell zone and boundary condition options available in ANSYS Fluent. Details regarding the cell zone and boundary condition inputs and the internal treatment at boundaries are provided.

The information in this chapter is divided into the following sections:

6.1. Overview
6.2. Cell Zone Conditions
6.3. Boundary Conditions
6.4. Non-Reflecting Boundary Conditions
6.5. User-Defined Fan Model
6.6. Profiles
6.7. Coupling Boundary Conditions with GT-Power
6.8. Coupling Boundary Conditions with WAVE

6.1. Overview

Cell zone and boundary conditions specify the flow and thermal variables on the boundaries of your physical model. They are, therefore, a critical component of your ANSYS Fluent simulations and it is important that they are specified appropriately.

6.1.1. Available Cell Zone and Boundary Types
6.1.2. The Cell Zone and Boundary Conditions Task Page
6.1.3. Changing Cell and Boundary Zone Types
6.1.4. Setting Cell Zone and Boundary Conditions
6.1.5. Copying Cell Zone and Boundary Conditions
6.1.6. Changing Cell or Boundary Zone Names
6.1.7. Defining Non-Uniform Cell Zone and Boundary Conditions
6.1.8. Defining and Viewing Parameters
6.1.9. Selecting Cell or Boundary Zones in the Graphics Display
6.1.10. Operating and Periodic Conditions
6.1.11. Highlighting Selected Boundary Zones
6.1.12. Saving and Reusing Cell Zone and Boundary Conditions

6.1.1. Available Cell Zone and Boundary Types

The boundary types available in ANSYS Fluent are classified as follows:

- Flow inlet and exit boundaries: pressure inlet, velocity inlet, mass flow inlet, and inlet vent, intake fan, pressure outlet, pressure far-field, outflow, outlet vent, and exhaust fan.
- Wall, repeating, and pole boundaries: wall, symmetry, periodic, and axis.
- Internal face boundaries: fan, radiator, porous jump, wall, and interior.

Cell zones consist of fluids and solids, with porous media treated as a type of fluid zone.
(The internal face boundary conditions are defined on cell faces, which means that they do not have a finite thickness and they provide a means of introducing a step change in flow properties. These boundary conditions are used to implement physical models representing fans, thin porous membranes, and radiators. The “interior” type of internal face zone does not require any input from you.)

In this chapter, the cell zones and boundary conditions listed above will be described in detail, and an explanation of how to set them and where they are most appropriately used will be provided. Note that while periodic boundaries are described in Periodic Boundary Conditions (p. 332), additional information about modeling fully-developed periodic flows is provided in Periodic Flows (p. 514).

6.1.2. The Cell Zone and Boundary Conditions Task Page

The Cell Zone Conditions and Boundary Conditions task page (Figure 6.1: The Boundary Conditions Task Page (p. 202)) allows you to change the cell zone or boundary zone type for a given zone and open other dialog boxes to set the cell zone and boundary condition parameters for each zone.

Cell Zone Conditions

Boundary Conditions

Figure 6.1: The Boundary Conditions Task Page
Changing Cell and Boundary Zone Types (p. 203) – Saving and Reusing Cell Zone and Boundary Conditions (p. 215) explain how to perform these operations with the Cell Zone Conditions or Boundary Conditions task page, and how to use the mouse and the graphics display in conjunction with the dialog box.

6.1.3. Changing Cell and Boundary Zone Types

Before you set any cell zone or boundary conditions, you should check the zone types of all boundary zones and change any if necessary. For example, if your mesh includes a pressure inlet, but you want to use a velocity inlet instead, you will need to change the pressure-inlet zone to a velocity-inlet zone.

The steps for changing a zone type are as follows:

1. In the Cell Zone Conditions or Boundary Conditions task page, select the zone to be changed in the Zone list.
2. Choose the correct zone type from the Type drop-down list.
3. Confirm the change when prompted by the Question Dialog Box (p. 15).

Once you have confirmed the change, the zone type will be changed, the name will change automatically (if the original name was the default name for that zone—see Changing Cell or Boundary Zone Names (p. 206)), and the dialog box for setting conditions for the zone will open automatically.

Important

When changing a wall and wall-shadow pair to one of the other internal face types (interior, radiator, porous-jump, fan), you can select either the wall or the wall-shadow to change. In
either case, the resulting zone will retain the ID and orientation of the wall zone and the wall-shadow zone will be deleted.

---

**Important**

Note that you cannot use this method to change zone types to or from the periodic type, since additional restrictions exist for this boundary type. *Creating Conformal Periodic Zones (p. 184)* explains how to create and uncouple periodic zones.

---

**Important**

If you are using one of the general multiphase models (VOF, mixture, or Eulerian), the procedure for changing types is slightly different. See *Steps for Setting Boundary Conditions (p. 1269)* for details.

---

### 6.1.3.1. Categories of Zone Types

You should be aware that you can only change zone types within each category listed in *Table 6.1: Zone Types Listed by Category (p. 204).* (Note that a double-sided face zone is a zone that separates two different cell zones or regions.)

**Table 6.1: Zone Types Listed by Category**

<table>
<thead>
<tr>
<th>Category</th>
<th>Zone Types</th>
</tr>
</thead>
<tbody>
<tr>
<td>Faces</td>
<td>axis, outflow, mass flow inlet, pressure far-field, pressure inlet, pressure outlet, symmetry, velocity inlet, wall, inlet vent, intake fan, outlet vent, exhaust fan</td>
</tr>
<tr>
<td>Double-Sided Faces</td>
<td>fan, interior, porous jump, radiator, wall</td>
</tr>
<tr>
<td>Periodic</td>
<td>periodic</td>
</tr>
<tr>
<td>Cells</td>
<td>fluid, solid (porous is a type of fluid cell)</td>
</tr>
</tbody>
</table>

---

### 6.1.4. Setting Cell Zone and Boundary Conditions

In ANSYS Fluent, boundary conditions are associated with zones, not with individual faces or cells. If you want to combine two or more zones that will have the same boundary conditions, see *Merging Zones (p. 176)* for information about merging zones.

To set cell zone and boundary conditions for a particular zone, perform one of the following sequences:

1. Select the zone from the Zone list in the Cell Zone Conditions or Boundary Conditions task page.

2. Click the Edit... button.

or

1. Choose the zone in the Zone list.

2. Click the selected zone type from the Type drop-down list.

or
1. Double-click the zone in the Zone list.

The dialog box for the selected cell or boundary zone will open, and you can specify the appropriate conditions.

---

**Important**

If you are using one of the general multiphase models (VOF, mixture, or Eulerian), the procedure for setting conditions is slightly different from that described above. See Steps for Setting Boundary Conditions (p. 1269) for details.

---

Note that when you use the define/boundary-conditions/[wall, velocity-inlet, etc . . . ] text command to set boundary conditions of a specified type, you can use a wildcard (*). This allows you to set boundary conditions to zones of the same type with compatible inputs or to a single zone. For example, if you want to set boundary conditions for wall-12, wall-15, and wall-17 etc. using the TUI command define/boundary-conditions/wall, enter wall-* when prompted to enter the zone name in order to switch to the wildcard option, and then follow the prompts.

### 6.1.5. Copying Cell Zone and Boundary Conditions

You can copy cell zones and boundary conditions from one zone to other zones of the same type. If, for example, you have several wall zones in your model and they all have the same boundary conditions, you can set the conditions for one wall, and then simply copy them to the others.

The procedure for copying cell zone or boundary conditions is as follows:

1. In the Cell Zone Conditions or Boundary Conditions task page, click the Copy... button. This will open the Copy Conditions dialog box (Figure 6.2: The Copy Conditions Dialog Box (p. 205)).

**Figure 6.2: The Copy Conditions Dialog Box**

![Copy Conditions Dialog Box](image)

2. In the From Cell Zone or From Boundary Zone list, select the zone that has the conditions you want to copy.

3. In the To Cell Zones or To Boundary Zones list, select the zone or zones to which you want to copy the conditions.
4. Click **Copy**. ANSYS Fluent will set *all* of the cell zones or boundary conditions for the zones selected in the **To Cell Zones** or **To Boundary Zones** list to be the same as the conditions for the zone selected in the **From Cell Zone** or **From Boundary Zone** list. (You cannot copy a subset of the conditions, such as only the thermal conditions.)

Note that you cannot copy conditions from external walls to internal (that is, two-sided) walls, or vice versa, if the energy equation is being solved, since the thermal conditions for external and internal walls are different.

---

**Important**

If you are using one of the general multiphase models (VOF, mixture, or Eulerian), the procedure for copying boundary conditions is slightly different. See **Steps for Copying Cell Zone and Boundary Conditions (p. 1273)** for details.

---

**6.1.6. Changing Cell or Boundary Zone Names**

The default name for a zone is its type plus an ID number (for example, pressure-inlet-7). In some cases, you may want to assign more descriptive names to the boundary zones. If you have two pressure-inlet zones, for example, you might want to rename them small-inlet and large-inlet. (Changing the name of a zone will *not* change its type. Instructions for changing a zone's type are provided in **Changing Cell and Boundary Zone Types (p. 203)**.)

To rename a zone, follow these steps:

1. Select the zone to be renamed in the **Zones** list in the **Cell Zone Conditions** or **Boundary Conditions** task page.
2. Click **Edit...** to open the dialog box for the selected zone.
3. Enter a new name under **Zone Name**.
4. Click the **OK** button.

Note that if you specify a new name for a zone and then change its type, the name you specified will be retained; the automatic name change that accompanies a change in type occurs only if the name of the zone is its type plus its ID.

**6.1.7. Defining Non-Uniform Cell Zone and Boundary Conditions**

Most conditions at each type of boundary zone can be defined as profile functions instead of constant values. You can use a profile contained in an externally generated profile file, or a function that you create using a user-defined function (UDF). Profiles are described in **Profiles (p. 377)**, and user-defined functions are described in the separate **UDF Manual**.

**6.1.8. Defining and Viewing Parameters**

You can define a series of cases based on a set of parametric values. These parameters may be defined for numeric cell zone and boundary condition settings. This is especially useful if you are using Workbench and performing parametric studies (optimization), comparing cases with different boundary settings. Information about this feature can be found in see **Working with Parameters and Design Points** in the **Workbench User’s Guide**. If you are not running ANSYS Fluent through Workbench, then you can use
the parameter settings to define the same boundary condition value to different boundaries having
the same units.

**Note**

For more information about using parameters with ANSYS Fluent in ANSYS Workbench, see
*Working With Input and Output Parameters in Workbench* in the separate *Fluent in Workbench
User’s Guide*.

The parameters that you have defined in the various boundary condition dialog boxes are accessed by
clicking the *Parameters*... button in the *Cell Zone Conditions* or *Boundary Conditions* task page. The
*Parameters* dialog box will open, as shown in Figure 6.3: The Parameters Dialog Box (p. 207), listing all
of the input parameters that you have created in the various boundary condition dialog boxes.

**Figure 6.3: The Parameters Dialog Box**

![Parameters dialog box](image)

In the *Parameters* dialog box, under the *Input Parameters* list, you can

- Edit the input properties using the *Input Parameter Properties* dialog box, which is the same dialog box
  used to create parameters. This dialog box can also be accessed by selecting *New Input Parameter*...
  from the drop-down lists in the boundary conditions dialog boxes, as described later in this section.

  **Important**

  If you are using ANSYS Fluent in ANSYS Workbench, you cannot edit the input parameters,
  you can only view them. For more information, see the separate *ANSYS Fluent in ANSYS
  Workbench User’s Guide*.

- Delete input parameters that are not assigned to a setting.
- More options exist under the *More* menu (see *Working With Advanced Parameter Options (p. 210)*):
Use in Scheme Procedure

displays the Use Input Parameter in Scheme Procedure Dialog Box (p. 2369) where you can apply an input parameter using a Scheme procedure.

Use in UDF

displays the Use Input Parameter in UDF Dialog Box (p. 2370) where you can make an input parameter available in a user-defined function.

In the Parameters dialog box, under the Output Parameters list, you can also

- Create output parameters. These are single values generated by existing reports. The types of output that may be generated are Fluxes..., Forces..., Surface Integrals..., Volume Integrals..., and User Defined...
  These output parameters are discussed in greater detail in Creating Output Parameters (p. 1743).

- Edit existing output parameters.

- More options exist under the More menu:

  **Delete**
  removes the selected output parameter from the list of Output Parameters.

  **Rename**
  allows you to edit the name of the output parameter through the Rename dialog box.

  **Print to Console**
  will output values to the console window. If you select multiple output parameters, then the output includes values from multiple output parameters.

  **Print All to Console**
  outputs the values from all output parameters to the console window.

  **Write...**
  allows you to store the output to a file. A dialog box is displayed allowing you to provide a file name.

  **Write All...**
  prompts you for a file name and then writes the values for all of the output parameters to a file.

---

**Important**

Changing the units for a quantity changes the value for any input parameter using that quantity.

---

**Note**

Various ANSYS Fluent setup-related input quantities (of type real and profile) can be assigned to an input parameter (indicated by the New Input Parameter... option in the corresponding drop-down list or by a small “p” icon next to the field). Clicking this option or icon displays the Select Input Parameter Dialog Box (p. 2097) where you can create and assign input parameters.
6.1.8.1. Creating a New Parameter

You can create a new cell zone or boundary condition parameter, as shown in Figure 6.4: The New Input Parameter... Selection (p. 209).

Figure 6.4: The New Input Parameter... Selection

When you select New Input Parameter... from the drop-down list, the Input Parameter Properties dialog box (Figure 6.5: The Input Parameter Properties Dialog Box (p. 210)) will open where you will

• Enter the Name of the parameter.

• Specify the Current Value as a constant.

• The Used In field displays information about where the parameter is utilized.
Once the parameters are defined in the **Input Parameter Properties** dialog box, the name of the parameter will appear in the drop-down list of the property you are defining, as seen in Figure 6.4: The New Input Parameter... Selection (p. 209).

---

**Note**

ANSYS Fluent automatically creates generic default names for new input and output parameters (for example, parameter-1, parameter-2, parameter-3, etc.) If a parameter is deleted, the default name is not reused. For example, if you have parameter-1, parameter-2, and parameter-3, then delete parameter-2 and create a new parameter, the default name for the new parameter will be parameter-4.

### 6.1.8.2. Working With Advanced Parameter Options

Various ANSYS Fluent setup related input quantities can be assigned to an input parameter. You can define a series of simulations based on a set of parametric values that are managed both in ANSYS Fluent and in Workbench. These parameters may be defined for numeric cell zone and boundary condition settings using the **New Input Parameter** ... option in the corresponding drop-down list or by a small "p" icon adjacent to a specific input setting. However, various ANSYS Fluent settings are not supported by these methods.

You can mitigate this limitation using input parameters through Scheme procedures and user-defined functions (UDFs), and define input parameters for various ANSYS Fluent simulation related settings.  
6.1.8.2.1. Defining Scheme Procedures With Input Parameters  
6.1.8.2.2. Defining UDFs With Input Parameters  
6.1.8.2.3. Using the Text User Interface to Define UDFs and Scheme Procedures With Input Parameters

### 6.1.8.2.1. Defining Scheme Procedures With Input Parameters

To use a Scheme procedure with input parameters, in the **Parameters** dialog box under **Input Parameters**, select More, then choose **Use in Scheme Procedure** to display the **Use Input Parameter in Scheme Procedure Dialog Box** (p. 2369) where you can register the input parameters that can be used in Scheme procedures during calculations. A text user interface command is also available, described in Using the Text User Interface to Define UDFs and Scheme Procedures With Input Parameters (p. 212).
Use the Select button to open the Select Input Parameter Dialog Box (p. 2097) where an input parameter can be chosen. Enter a Scheme Procedure name or body starting with lambda that should receive a real argument (the value of the selected input parameter). For example, if the following Scheme procedure called my-funct is defined as a Scheme file that gets loaded into the current session,

```scheme
(define my-funct
  (lambda (value
    (ti-menu-load-string (format #f "/solve/set/under-relaxation/pressure ~g" value)))))
```

then enter my-funct for the Scheme Procedure. Otherwise, you can directly enter the following code for the Scheme Procedure:

```scheme
(lambda (val)
  (ti-menu-load-string (args->string '/solve/set/under-relaxation/pressure value)))
```

Click Define to populate the Registered List. Use Delete to delete the use of the selected input variable, but not the associated input parameter (the input parameter has to be deleted separately in the Parameters dialog box). Use Print to print out details of the registered input parameters.

---

**Important**

While writing Scheme procedures, you should use the "args->string" help procedure instead of using double quotes. For example:

```scheme
(lambda (value1)
  (display (args->string 'Changing-Theta-Divisions-value= value1))
  (ti-menu-load-string
    (args->string '/define/models/radiation/discrete-ordinates? 'yes value1 '_ _ _' ))
)
```

Alternatively, you could also write:

```scheme
(lambda (value1)
  (display (args->string 'Changing-Theta-Divisions-value= value1))
  (ti-menu-load-string
    (apply args->string `(/define/models/radiation/discrete-ordinates? yes ,value1 _ _ _ _)))
)
```

where the ` character after args->string is the grave accent character (not a single quote) and the _ character stores the default value of the current text user interface prompt. Note
that the first occurrence of value1 is the Scheme variable, while the second occurrence of value1 will be replaced by the value stored in the variable. This method eliminates the need to specify a single quote for all arguments.

Also note that if you enter a scheme procedure body in the Use Input Parameter in Scheme Procedure dialog box, you should combine the scheme procedure lines into one single line.

6.1.8.2.2. Defining UDFs With Input Parameters

To use a UDF with input parameters, in the Parameters dialog box under Input Parameters, select More, then choose Use in UDF to display the Use Input Parameter in UDF Dialog Box (p. 2370) where you can register the input parameters that can be used in UDF functions during calculations. A text user interface command is also available, described in Using the Text User Interface to Define UDFs and Scheme Procedures With Input Parameters (p. 212).

Figure 6.7: Use Input Parameter in UDF Dialog Box

![Use Input Parameter in UDF Dialog Box](image)

Use the Select button to open the Select Input Parameter Dialog Box (p. 2097) where an input parameter can be chosen. Click Define to populate the Registered List. Use Delete to delete the use of the selected input variable, but not the associated input parameter (the input parameter has to be deleted separately in the Parameters dialog box). Click Print to print out the parameter ID of the registered input parameter. This ID should be used to access the value of the parameter in UDF.

By registering the input parameter, ANSYS Fluent knows that this input parameter is being used by a UDF. In the UDF C function, you can access the registered input parameter value using the Get_Input_Parameter macro. For example,

```c
real value = Get_Input_Parameter("real-4"),
```

where real-4 is an input parameter ID obtained using the Print feature.

6.1.8.2.3. Using the Text User Interface to Define UDFs and Scheme Procedures With Input Parameters

The /define/parameters/input-parameters/advance/use-in text interface command can also be used to define input parameters and Scheme procedures and user-defined functions.
The Scheme procedures can use other text user interface (TUI) commands in ANSYS Fluent to change the desired simulation settings in a parametric manner. Each numerical component of the TUI command string can be marked and treated as a parameter. Setting up advanced input parameters requires using Scheme functions that use text interface commands to apply new values. Once defined, these input parameters are displayed in the Parameters dialog box alongside other input parameters. The input parameter passes a constant numeric value to the registered/provided Scheme function. Therefore, the associated Scheme function (and corresponding ANSYS Fluent text command) uses the constant parameter values using the units that were already defined for the designated text command quantity.

```
define/parameters/input-parameters/advance
Enter the advanced input parameters menu.

use-in/
 Allows you to use an input parameter in a Scheme procedure or in a UDF. The following examples demonstrates how to use an input parameter using a Scheme procedure. The Scheme procedure body can be written at the prompt itself:

```
define/parameters/input-parameters/advance> use-in
Select type: scheme-proc
Name of parameter ["parameter-1"]
  parameter-1 value [0] 0.3
Enter the name/body of apply-function [()] (lambda (value )
  (ti-menu-load-string (format #f "/solve/set/under-relaxation/pressure ~g" value)))
```

or it can be written in a Scheme file (for example, my-funct)

```
define/parameters/custom-input-parameters> use-in
Select type: scheme-proc
Name of parameter ["parameter-1"]
  parameter-1 value [0] 0.3
Enter the name/body of apply-function [()] my-funct
```

where the my-funct Scheme file contents are:

```
(define my-funct
  (lambda (value )
    (ti-menu-load-string (format #f "/solve/set/under-relaxation/pressure ~g" value))))
```

The following example demonstrates how to use an input parameter using a UDF:

```
define/parameters/input-parameters/advance> use-in
Select type: udf-side
Name of parameter ["parameter-1"]
  parameter-1 value [0] 0.3
```

```
define/parameters/input-parameters/advance> use-in
Select type: udf-side
Name of parameter ["parameter-1"]
  parameter-1 value [0] 0.3
```

```
define/parameters/input-parameters/advance> use-in
Select type: udf-side
Name of parameter ["parameter-1"]
  parameter-1 value [0] 0.3
```

```
define/parameters/input-parameters/advance> use-in
Select type: udf-side
Name of parameter ["parameter-1"]
  parameter-1 value [0] 0.3
```

```
define/parameters/input-parameters/advance> use-in
Select type: udf-side
Name of parameter ["parameter-1"]
  parameter-1 value [0] 0.3
```

```
define/parameters/input-parameters/advance> use-in
Select type: udf-side
Name of parameter ["parameter-1"]
  parameter-1 value [0] 0.3
```

```
define/parameters/input-parameters/advance> use-in
Select type: udf-side
Name of parameter ["parameter-1"]
  parameter-1 value [0] 0.3
```

```
define/parameters/input-parameters/advance> use-in
Select type: udf-side
Name of parameter ["parameter-1"]
  parameter-1 value [0] 0.3
```

```
define/parameters/input-parameters/advance> use-in
Select type: udf-side
Name of parameter ["parameter-1"]
  parameter-1 value [0] 0.3
```

```
define/parameters/input-parameters/advance> use-in
Select type: udf-side
Name of parameter ["parameter-1"]
  parameter-1 value [0] 0.3
```

```
define/parameters/input-parameters/advance> use-in
Select type: udf-side
Name of parameter ["parameter-1"]
  parameter-1 value [0] 0.3
```

```
define/parameters/input-parameters/advance> use-in
Select type: udf-side
Name of parameter ["parameter-1"]
  parameter-1 value [0] 0.3
```

```
define/parameters/input-parameters/advance> use-in
Select type: udf-side
Name of parameter ["parameter-1"]
  parameter-1 value [0] 0.3
```

```
define/parameters/input-parameters/advance> use-in
Select type: udf-side
Name of parameter ["parameter-1"]
  parameter-1 value [0] 0.3
```

```
define/parameters/input-parameters/advance> use-in
Select type: udf-side
Name of parameter ["parameter-1"]
  parameter-1 value [0] 0.3
```

```
define/parameters/input-parameters/advance> use-in
Select type: udf-side
Name of parameter ["parameter-1"]
  parameter-1 value [0] 0.3
```

delete
 Deletes the use of the selected input variable, but not the associated input parameter (the input parameter has to be deleted separately). Using the wildcard ‘*’ allows you to delete all custom input variable at once.

list
 Shows usage of input parameters for Scheme procedures and for UDFs

6.1.9. Selecting Cell or Boundary Zones in the Graphics Display

Whenever you need to select a zone in the Cell Zone Conditions or Boundary Conditions task page, you can use the mouse in the graphics window to choose the appropriate zone. This feature is particularly useful if you are setting up a problem for the first time, or if you have two or more zones of the same type and you want to determine the zone IDs (that is, figure out which zone is which). To use this feature, do the following:
1. Display the mesh using the Mesh Display Dialog Box (p. 1891).

2. Use the mouse probe button (the right button, by default—see Controlling the Mouse Button Functions (p. 1654) to modify the mouse button functions) to click a cell or boundary zone in the graphics window.

The zone you select in the graphics display will automatically be selected in the Zone list in the Cell Zone Conditions or Boundary Conditions task page, and its name and ID will be printed in the console window.

However, if you prefer to select the surfaces to display using the Mesh Display dialog box, then simply click the Display Mesh... button in the Cell Zone Conditions or Boundary Conditions task page.

Cell Zone Conditions → Display Mesh...

Boundary Conditions → Display Mesh...

Detailed information about the Mesh Display dialog box can be found in Displaying the Mesh (p. 1606).

6.1.10. Operating and Periodic Conditions

The Cell Zone Conditions and Boundary Conditions task pages allow you to access the Operating Conditions dialog box, where you can set the operating pressure, reference pressure location, include the effects of gravity, and specify other operating variables, as discussed in Modeling Basic Fluid Flow (p. 505).

Cell Zone Conditions → Operating Conditions...

Boundary Conditions → Operating Conditions...

The Periodic Conditions dialog box can be accessed from the Boundary Conditions task page. For a detailed description of this dialog box's inputs, refer to Periodic Flows (p. 514).

Boundary Conditions → Periodic Conditions...

6.1.11. Highlighting Selected Boundary Zones

To highlight a selected boundary zone of a model that is displayed in the graphics window, enable the Highlight Zone option in the Boundary Conditions task page.

Important

Note that this is only applicable to 3D cases and is available only in the Boundary Conditions task page.

There are two ways in which you can highlight a boundary zone in the graphics window, after enabling the Highlight Zone option:

• Select the zone by highlighting it in the Zone list, in the Boundary Conditions task page.

• Use the mouse-probe button and select the zone in the graphics window.
The selected zone in the graphics window will be highlighted in a cyan color, which is the default color. You can change the color using the following text command:

\[
\text{display} \rightarrow \text{set} \rightarrow \text{colors} \rightarrow \text{highlight-color}
\]

If you want to highlight a boundary zone that is not displayed in the graphics window, ANSYS Fluent will display that boundary zone in the graphics window and then highlight it. If you disable the Highlight Zone option, the displayed boundary zone will be removed from the scene (graphics window) and your model will be redrawn to its original view.

### 6.1.12. Saving and Reusing Cell Zone and Boundary Conditions

You can save cell zone and boundary conditions to a file so that you can use them to specify the same conditions for a different case, as described in Reading and Writing Boundary Conditions (p. 56).

### 6.2. Cell Zone Conditions

Cell zones consist of fluids and solids. Porous zones in ANSYS Fluent are treated as fluid zones. A detailed description of the various cell zones is given in the sections that follow.

- 6.2.1. Fluid Conditions
- 6.2.2. Solid Conditions
- 6.2.3. Porous Media Conditions
- 6.2.4. Fixing the Values of Variables
- 6.2.5. Locking the Temperature for Solid and Shell Zones
- 6.2.6. Defining Mass, Momentum, Energy, and Other Sources

#### 6.2.1. Fluid Conditions

A fluid zone is a group of cells for which all active equations are solved. The only required input for a fluid zone is the type of fluid material. You must indicate which material the fluid zone contains so that the appropriate material properties will be used.

**Important**

If you are modeling multiphase flow, you will not specify the materials here; you will choose the phase material when you define the phases, as described in Defining the Phases for the VOF Model (p. 1296).

**Important**

If you are modeling species transport and/or combustion, you can specify the material as either a mixture or a fluid. The mixture material has to be the same as that specified in the Species Model dialog box when you enable the model. The fluid zones, being of different material types, must not be contiguous.

Optional inputs allow you to set sources or fixed values of mass, momentum, heat (temperature), turbulence, species, and other scalar quantities. You can also define motion for the fluid zone. If there are rotationally periodic boundaries adjacent to the fluid zone, you must specify the rotation axis. If you are modeling turbulence using one of the $k-\varepsilon$ models, the $k-\omega$ model, or the Spalart-Allmaras model,
you can choose to define the fluid zone as a laminar flow region. If you are modeling radiation using the DO model, you can specify whether or not the fluid participates in radiation.

**Warning**

In general, disabling **Participates in Radiation** for fluid zones is not recommended, as it can produce erroneous results. There are rare cases when it is acceptable: for example, if the domain contains multiple fluid zones, disabling this option for zones where radiation is negligible may save computational time without affecting the results.

**Important**

For information about porous zones, see Porous Media Conditions (p. 223).

### 6.2.1.1. Inputs for Fluid Zones

You will set all fluid conditions in the Fluid Dialog Box (p. 2085) (Figure 6.8: The Fluid Dialog Box (p. 216)), which is accessed from the Cell Zone Conditions task page (as described in Setting Cell Zone and Boundary Conditions (p. 204)).

**Figure 6.8: The Fluid Dialog Box**

![Fluid Dialog Box](image)

**Warning**

In general, disabling **Participates in Radiation** for fluid zones is not recommended, as it can produce erroneous results. There are rare cases when it is acceptable: for example, if the domain contains multiple fluid zones, disabling this option for zones where radiation is negligible may save computational time without affecting the results.

**Important**

For information about porous zones, see Porous Media Conditions (p. 223).
6.2.1.1. Defining the Fluid Material

To define the material contained in the fluid zone, select the appropriate item in the **Material Name** drop-down list. This list will contain all fluid materials database) in the **Create/Edit Materials Dialog Box** (p. 2022). If you want to check or modify the properties of the selected material, you can click **Edit...** to open the **Edit Material** dialog box; this dialog box contains just the properties of the selected material, not the full contents of the standard **Create/Edit Materials** dialog box.

**Important**

If you are modeling species transport or multiphase flow, the **Material Name** list will not appear in the **Fluid** dialog box. For species calculations, the mixture material for all fluid zones will be the material you specified in the **Species Model Dialog Box** (p. 1943). For multiphase flows, the materials are specified when you define the phases, as described in **Defining the Phases for the VOF Model** (p. 1296).

6.2.1.1.2. Defining Sources

If you want to define a source of heat, mass, momentum, turbulence, species, or other scalar quantity within the fluid zone, you can do so by enabling the **Source Terms** option. See **Defining Mass, Momentum, Energy, and Other Sources** (p. 251) for details.

6.2.1.1.3. Defining Fixed Values

If you want to fix the value of one or more variables in the fluid zone, rather than computing them during the calculation, you can do so by enabling the **Fixed Values** option. See **Fixing the Values of Variables** (p. 247) for details.

6.2.1.1.4. Specifying a Laminar Zone

When you are calculating a turbulent flow, it is possible to “turn off” turbulence modeling in a specific fluid zone. To disable turbulence modeling, turn on the **Laminar Zone** option in the **Fluid** dialog box. This is useful if you know that the flow in a certain region is laminar. For example, if you know the location of the transition point on an airfoil, you can create a laminar/turbulent transition boundary where the laminar cell zone borders the turbulent cell zone. This feature allows you to model turbulent transition on the airfoil.

By default, the **Laminar Zone** option will set the turbulent viscosity, \( \mu_t \), to zero and disable turbulence production in the fluid zone. Turbulent quantities will still be transported through the zone, but effects on fluid mixing and momentum will be ignored. If you want to keep the turbulent viscosity, you can do so using the text command `define/boundary-conditions/fluid`. You will be asked if you want to Set Turbulent Viscosity to zero within laminar zone?. If your response is no, ANSYS Fluent will set the production term in the turbulence transport equation to zero, but will retain a non-zero \( \mu_t \).

Disabling turbulence modeling in a fluid zone can be applied to all the turbulence models except the Large Eddy Simulation (LES) model.

6.2.1.1.5. Specifying a Reaction Mechanism

If you are modeling species transport with reactions, you can enable a reaction mechanism in a fluid zone by turning on the **Reaction** option and selecting an available mechanism from the **Reaction**
**Mechanism** drop-down list. See *Defining Zone-Based Reaction Mechanisms (p. 904)* for more information about defining reaction mechanisms.

### 6.2.1.1.6. Specifying the Rotation Axis

If there are rotationally periodic boundaries adjacent to the fluid zone or if the zone is rotating, either the mesh or its reference frame, you must specify the rotation axis. To define the axis for a moving reference frame problem, set the **Rotation-Axis Direction** and **Rotation-Axis Origin** under the **Reference Frame** tab. To define the axis for a moving mesh problem, set the **Rotation-Axis Direction** and **Rotation-Axis Origin** under the **Mesh Motion** tab.

---

**Note**

If a frame motion and a mesh motion are specified at the same zone and this zone has rotationally periodic boundaries adjacent to it, then both axes have to be coaxial. Otherwise, the periodicity assumption is not valid and you will receive a warning message. In addition, the mesh check will fail.

The cell zone axis is independent of the axis of rotation used by any adjacent wall zones or any other cell zones. For 3D problems, the axis of rotation is the vector from the **Rotation-Axis Origin** in the direction of the vector given by your **Rotation-Axis Direction** inputs for the frame of reference and the mesh motion. For 2D non-axisymmetric problems, you will specify only the **Rotation-Axis Origin**; the axis of rotation is the \( z \)-direction vector passing through the specified point. (The \( z \) direction is normal to the plane of your geometry so that rotation occurs in the plane.) For 2D axisymmetric problems, you will not define the axis: the rotation will always be about the \( x \) axis, with the origin at (0,0).

### 6.2.1.1.7. Defining Zone Motion

To define zone motion for a moving reference frame (MRF), enable the **Frame Motion** option in the **Fluid** dialog box. Set the appropriate parameters in the expanded portion of the dialog box, under the **Reference Frame** tab.

To define zone motion for a moving (sliding) mesh, enable the **Mesh Motion** option in the **Fluid** dialog box. Set the appropriate parameters in the expanded portion of the dialog box, under the **Mesh Motion** tab. See *Setting Up the Sliding Mesh Problem (p. 566)* for details.

For cases that do not contain zones with motion specified in a relative frame to another zone, select **absolute** from the **Relative To Cell Zone** drop-down list. Here, the velocity and rotation components are specified in an **absolute** reference frame, which is the default setting, as shown in *Figure 6.9: Rotation Specified in the Absolute Reference Frame (p. 219)*. If no moving zones are present in the simulation, then **absolute** will be the only available selection. See *The Multiple Reference Frame Model* for more information.
For cases where you have a moving zone specified relative to another moving zone, select the cell zone carrying the primary motion from the Relative To Cell Zone drop-down list under the Reference Frame tab or the Mesh Motion tab. Note that for such cases, Rotation-Axis Origin (Relative) will appear in the interface, signifying coordinates relative to the zone selected from the Relative To Cell Zone drop-down list.

Figure 6.10: Rotation Specified Relative to a Moving Zone (p. 220) illustrates that the rotational axis origin of the small rotating zone is specified relative to the cell zone carrying the primary motion (having local coordinate system $R$).
Figure 6.10: Rotation Specified Relative to a Moving Zone

Note

The **Relative To Cell Zone** list will consist of all moving cell zones with an absolute motion specification (that is zones that are moving, but their motion is not relative to some other zone), excluding the current cell zone.

For problems that include linear, translational motion of the fluid zone, specify the **Translational Velocity** by setting the **X**, **Y**, and **Z** components under the **Mesh Motion** tab. For problems that include rotational motion, specify the rotational **Speed** under **Rotational Velocity**. The rotation axis is defined as described above. Note that the speed can be specified as a constant value or a transient profile. The transient profile may be in a file format, as described in Defining Transient Cell Zone and Boundary Conditions (p. 388), or a UDF macro (DEFINE_TRANSIENT_PROFILE). Specifying the individual velocities as either a profile or a UDF allows you to specify a single component of the frame motion individually. However, you can also specify the frame motion using a user-defined function. This may prove to be quite con-
venient if you are modeling a more complicated motion of the moving reference frame, where the hooking of many different user-defined functions or profiles can be cumbersome.

**Important**

If you need to switch between the MRF and moving mesh models, simply click the Copy To Mesh Motion for zones with a moving frame of reference and Copy to Frame Motion for zones with moving meshes to transfer motion variables, such as the axes, frame origin, and velocity components between the two models. The variables used for the origin, axis, and velocity components, as well as for the UDF DEFINE_ZONE_MOTION will be copied. This is particularly useful if you are doing a steady-state MRF simulation to obtain an initial solution for a transient Moving Mesh simulation in a turbomachine.

See Modeling Flows with Moving Reference Frames (p. 535) for details about modeling flows in moving reference frames. Details about the frame motion UDF can be found in DEFINE_ZONE_MOTION in the UDF Manual.

6.2.1.1.8. Defining Radiation Parameters

If you are using the DO radiation model, you can specify whether or not the fluid zone participates in radiation using the Participates in Radiation option. See Defining Boundary Conditions for Radiation (p. 798) for details.

6.2.2. Solid Conditions

A “solid” zone is a group of cells for which only a heat conduction problem is solved; no flow equations are solved. The material being treated as a solid may actually be a fluid, but it is assumed that no convection is taking place. The only required input for a solid zone is the type of solid material. You must indicate which material the solid zone contains so that the appropriate material properties will be used. Optional inputs allow you to set a volumetric heat generation rate (heat source) or a fixed value of temperature. You can also define motion for the solid zone. If there are rotationally periodic boundaries adjacent to the solid zone, you must specify the rotation axis. If you are modeling radiation using the DO model, you can specify whether or not the solid material participates in radiation.

6.2.2.1. Inputs for Solid Zones

You will set all solid conditions in the Solid Dialog Box (p. 2092) (Figure 6.11: The Solid Dialog Box (p. 222)), which is opened from the Cell Zone Conditions task page (as described in Setting Cell Zone and Boundary Conditions (p. 204)).
6.2.2.1.1. Defining the Solid Material

To define the material contained in the solid zone, select the appropriate item in the Material Name drop-down list. This list will contain all solid materials database) in the Create/Edit Materials Dialog Box (p. 2022). If you want to check or modify the properties of the selected material, you can click Edit... to open the Edit Material dialog box; this dialog box contains just the properties of the selected material, not the full contents of the standard Create/Edit Materials dialog box.

6.2.2.1.2. Defining a Heat Source

If you want to define a source of heat within the solid zone, you can do so by enabling the Source Terms option. See Defining Mass, Momentum, Energy, and Other Sources (p. 251) for details.

6.2.2.1.3. Defining a Fixed Temperature

If you want to fix the value of temperature in the solid zone, rather than computing it during the calculation, you can do so by enabling the Fixed Values option. See Fixing the Values of Variables (p. 247) for details.
6.2.2.1.4. Specifying the Rotation Axis

If there are rotationally periodic boundaries adjacent to the solid zone or if the zone is rotating, either the mesh or its reference frame, you must specify the rotation axis. To define the axis for a moving reference frame problem, set the **Rotation-Axis Direction** and **Rotation-Axis Origin** under the **Reference Frame** tab. To define the axis for a moving mesh problem, set the **Rotation-Axis Direction** and **Rotation-Axis Origin** under the **Mesh Motion** tab.

**Note**

If a frame motion and a mesh motion are specified at the same zone and this zone has rotationally periodic boundaries adjacent to it, then both axes have to be coaxial. Otherwise, the periodicity assumption is not valid and you will receive a warning message. In addition, the mesh check will fail.

The cell zone axis is independent of the axis of rotation used by any adjacent wall zones or any other cell zones. For 3D problems, the axis of rotation is the vector from the **Rotation-Axis Origin** in the direction of the vector given by your **Rotation-Axis Direction** inputs for the frame of reference and the mesh motion. For 2D non-axisymmetric problems, you will specify only the **Rotation-Axis Origin**; the axis of rotation is the z-direction vector passing through the specified point. (The z direction is normal to the plane of your geometry so that rotation occurs in the plane.) For 2D axisymmetric problems, you will not define the axis: the rotation will always be about the x axis, with the origin at (0,0).

6.2.2.1.5. Defining Zone Motion

Defining zone motion in solids is similar to defining them for fluids. Refer to Defining Zone Motion (p. 218) for details.

6.2.2.1.6. Defining Radiation Parameters

If you are using the DO radiation model, you can specify whether or not the solid material participates in radiation using the **Participates in Radiation** option. See Defining Boundary Conditions for Radiation (p. 798) for details.

6.2.3. Porous Media Conditions

The porous media model can be used for a wide variety of single phase and multiphase problems, including flow through packed beds, filter papers, perforated plates, flow distributors, and tube banks. When you use this model, you define a cell zone in which the porous media model is applied and the pressure loss in the flow is determined via your inputs as described in Momentum Equations for Porous Media (p. 224). Heat transfer through the medium can also be represented, with or without the assumption of thermal equilibrium between the medium and the fluid flow (as described in Treatment of the Energy Equation in Porous Media (p. 226)).

A 1D simplification of the porous media model, termed the “porous jump,” can be used to model a thin membrane with known velocity/pressure-drop characteristics. The porous jump model is applied to a face zone, not to a cell zone, and should be used (instead of the full porous media model) whenever possible because it is more robust and yields better convergence. See Porous Jump Boundary Conditions (p. 350) for details.
6.2.3.1. Limitations and Assumptions of the Porous Media Model

The porous media model incorporates an empirically determined flow resistance in a region of your model defined as “porous”. In essence, the porous media model adds a momentum sink in the governing momentum equations. Consequently, the following modeling assumptions and limitations should be readily recognized:

- Since the volume blockage that is physically present is not represented in the model, by default ANSYS Fluent uses and reports a superficial velocity inside the porous medium, based on the volumetric flow rate, to ensure continuity of the velocity vectors across the porous medium interface. This superficial velocity formulation does not take porosity into account when calculating the convection and diffusion terms of the transport equations. You can choose to use a more accurate alternative, in which the true (physical) velocity is calculated inside the porous medium and porosity is included in the differential terms of the transport equations. See *Modeling Porous Media Based on Physical Velocity* (p. 243) for details. In a multiphase flow system, all phases share the same porosity.

- The effect of the porous medium on the turbulence field is only approximated. See *Treatment of Turbulence in Porous Media* (p. 228) for details.

- In general, the ANSYS Fluent porous medium model, for both single phase and multiphase, assumes the porosity is isotropic, and it can vary with space and time.

- The Superficial Velocity Formulation and the Physical Velocity Formulation are available for multiphase porous media. See *User Inputs for Porous Media* (p. 229) for details.

- The porous media momentum resistance and heat source terms are calculated separately on each phase. See *Momentum Equations for Porous Media* (p. 224) for details.

- A unique pressure interpolation scheme is always used inside porous media zones regardless of the pressure scheme selected in the Solution Methods task page.

- The interactions between a porous medium and shock waves are not considered.

- When applying the porous media model in a moving reference frame, ANSYS Fluent will either apply the relative reference frame or the absolute reference frame when you enable the Relative Velocity Resistance Formulation. This allows for the correct prediction of the source terms.

- Standard Initialization is the recommended initialization method for porous media simulations. The default Hybrid Initialization method does not account for the porous media properties, and depending on boundary conditions, may produce an unrealistic initial velocity field. For porous media simulations, the Hybrid Initialization method can only be used with the Constant Velocity Vector option.

6.2.3.2. Momentum Equations for Porous Media

The porous media models for single phase flows and multiphase flows use the Superficial Velocity Porous Formulation as the default. ANSYS Fluent calculates the superficial phase or mixture velocities based on the volumetric flow rate in a porous region. The porous media model is described in the following sections for single phase flow; however, it is important to note the following for multiphase flow:

- In the Eulerian multiphase model (*Eulerian Model Theory* in the Theory Guide), the general porous media modeling approach, physical laws, and equations described below are applied to the corresponding phase for mass continuity, momentum, energy, and all the other scalar equations.
The **Superficial Velocity Porous Formulation** generally gives good representations of the bulk pressure loss through a porous region. However, since the superficial velocity values within a porous region remain the same as those outside the porous region, it cannot predict the velocity increase in porous zones and therefore limits the accuracy of the model.

Porous media are modeled by the addition of a momentum source term to the standard fluid flow equations. The source term is composed of two parts: a viscous loss term (Darcy, the first term on the right-hand side of Equation 6.1 (p. 225), and an inertial loss term (the second term on the right-hand side of Equation 6.1 (p. 225))

\[
S_i = -\left( \sum_{j=1}^{3} D_{ij} \nu_j + \sum_{j=1}^{3} C_{ij} \frac{1}{2} \rho |\nu| \nu_j \right)
\]  

(6.1)

where \(S_i\) is the source term for the \(i\) th (\(x\), \(y\), or \(z\)) momentum equation, \(|\nu|\) is the magnitude of the velocity and \(D\) and \(C\) are prescribed matrices. This momentum sink contributes to the pressure gradient in the porous cell, creating a pressure drop that is proportional to the fluid velocity (or velocity squared) in the cell.

To recover the case of simple homogeneous porous media

\[
S_i = -\left( \frac{\mu}{\alpha} \nu_i + C_2 \frac{1}{2} \rho |\nu| \nu_i \right)
\]  

(6.2)

where \(\alpha\) is the permeability and \(C_2\) is the inertial resistance factor, simply specify \(D\) and \(C\) as diagonal matrices with \(1/\alpha\) and \(C_2\), respectively, on the diagonals (and zero for the other elements).

ANSYS Fluent also allows the source term to be modeled as a power law of the velocity magnitude:

\[
S_i = -C_0 |\nu|^{C_1} = -C_0 |\nu|^{(C_1 - 1)} \nu_i
\]  

(6.3)

where \(C_0\) and \(C_1\) are user-defined empirical coefficients.

---

**Important**

In the power-law model, the pressure drop is isotropic and the units for \(C_0\) are SI.

---

**6.2.3.2.1. Darcy's Law in Porous Media**

In laminar flows through porous media, the pressure drop is typically proportional to velocity and the constant \(C_2\) can be considered to be zero. Ignoring convective acceleration and diffusion, the porous media model then reduces to Darcy's Law:

\[
\nabla \rho = -\frac{\mu}{\alpha} \nabla \nu
\]  

(6.4)

The pressure drop that ANSYS Fluent computes in each of the three \((x, y, z)\) coordinate directions within the porous region is then
\[ \Delta p_x = \sum_{j=1}^{3} \frac{\mu}{\alpha_{xj}} v_j \Delta n_x \]
\[ \Delta p_y = \sum_{j=1}^{3} \frac{\mu}{\alpha_{yj}} v_j \Delta n_y \]
\[ \Delta p_z = \sum_{j=1}^{3} \frac{\mu}{\alpha_{zj}} v_j \Delta n_z \] (6.5)

where \(1/\alpha_{ij}\) are the entries in the matrix \(D\) in Equation 6.1 (p. 225), \(v_j\) are the velocity components in the \(x\), \(y\), and \(z\) directions, and \(\Delta n_{x'y'}\Delta n_{y'y'}\Delta n_{z'z'}\) are the thicknesses of the medium in the \(x\), \(y\), and \(z\) directions.

Here, the thickness of the medium \((\Delta n_{x'y'}\Delta n_{y'y'}\Delta n_{z'z'})\) is the actual thickness of the porous region in your model. Therefore if the thicknesses used in your model differ from the actual thicknesses, you must make the adjustments in your inputs for \(1/\alpha_{ij}\).

**6.2.3.2.2. Inertial Losses in Porous Media**

At high flow velocities, the constant \(C_2\) in Equation 6.1 (p. 225) provides a correction for inertial losses in the porous medium. This constant can be viewed as a loss coefficient per unit length along the flow direction, thereby allowing the pressure drop to be specified as a function of dynamic head.

If you are modeling a perforated plate or tube bank, you can sometimes eliminate the permeability term and use the inertial loss term alone, yielding the following simplified form of the porous media equation:

\[ \nabla p = -\sum_{j=1}^{3} C_{2j} \left( \frac{1}{2} \rho v_j |v_j| \right) \] (6.6)

or when written in terms of the pressure drop in the \(x\), \(y\), \(z\) directions:

\[ \Delta p_x \approx \sum_{j=1}^{3} C_{2xj} \Delta n_{x'} \frac{1}{2} \rho v_j |v_j| \]
\[ \Delta p_y \approx \sum_{j=1}^{3} C_{2yj} \Delta n_{y'} \frac{1}{2} \rho v_j |v_j| \] (6.7)
\[ \Delta p_z \approx \sum_{j=1}^{3} C_{2zj} \Delta n_{z'} \frac{1}{2} \rho v_j |v_j| \]

Again, the thickness of the medium \((\Delta n_{x'},\Delta n_{y'},\Delta n_{z'})\) is the thickness you have defined in your model.

**6.2.3.3. Treatment of the Energy Equation in Porous Media**

ANSYS Fluent solves the standard energy transport equation (Equation 5.1 in the Theory Guide) in porous media regions with modifications to the conduction flux and the transient terms only.
### 6.2.3.3.1. Equilibrium Thermal Model Equations

For simulations in which the porous medium and fluid flow are assumed to be in thermal equilibrium, the conduction flux in the porous medium uses an effective conductivity and the transient term includes the thermal inertia of the solid region on the medium:

\[
\frac{\partial}{\partial t} \left( \gamma \rho_f E_f + \left(1 - \gamma \right) \rho_s E_s \right) + \nabla \cdot \left( \bar{v} \left( \rho_f E_f + p \right) \right) = S_f^h + \nabla \cdot \left[ k_{\text{eff}} \nabla T - \left( \sum_i h_{fi} \right) + (\bar{\tau} \cdot \nabla) \right]
\]

(6.8)

where:

- \( E_f \) = total fluid energy
- \( E_s \) = total solid medium energy
- \( \rho_f \) = fluid density
- \( \rho_s \) = solid medium density
- \( \gamma \) = porosity of the medium
- \( k_{\text{eff}} \) = effective thermal conductivity of the medium
- \( S_f^h \) = fluid enthalpy source term

The effective thermal conductivity in the porous medium, \( k_{\text{eff}} \), is computed by ANSYS Fluent as the volume average of the fluid conductivity and the solid conductivity:

\[
k_{\text{eff}} = \gamma k_f + \left(1 - \gamma \right) k_s
\]

(6.9)

where:

- \( k_f \) = fluid phase thermal conductivity (including the turbulent contribution, \( k_{Tf} \))
- \( k_s \) = solid medium thermal conductivity

The fluid thermal conductivity \( k_f \) and the solid thermal conductivity \( k_s \) can be computed via user-defined functions.

The anisotropic effective thermal conductivity can also be specified via user-defined functions. In this case, the isotropic contributions from the fluid, \( \gamma k_f \), are added to the diagonal elements of the solid anisotropic thermal conductivity matrix.

### 6.2.3.3.2. Non-Equilibrium Thermal Model Equations

For simulations in which the porous medium and fluid flow are not assumed to be in thermal equilibrium, a dual cell approach is used. In such an approach, a solid zone that is spatially coincident with the porous fluid zone is defined, and this solid zone only interacts with the fluid with regard to heat transfer. The conservation equations for energy are solved separately for the fluid and solid zones. The conservation equation solved for the fluid zone is
and the conservation equation solved for the solid zone is
\[
\frac{\partial}{\partial t} \left( (1 - \gamma) \rho_s E_s \right) = \nabla \cdot \left( (1 - \gamma) k_s \nabla T_s \right) + S_s^h + h_{fs} A_{fs} (T_s - T_f) \tag{6.11}
\]

where

\[ E_f = \text{total fluid energy} \]
\[ E_s = \text{total solid medium energy} \]
\[ \rho_f = \text{fluid density} \]
\[ \rho_s = \text{solid medium density} \]
\[ \gamma = \text{porosity of the medium} \]
\[ k_f = \text{fluid phase thermal conductivity (including the turbulent contribution, } k_I) \]
\[ k_s = \text{solid medium thermal conductivity} \]
\[ h_{fs} = \text{heat transfer coefficient for the fluid / solid interface} \]
\[ A_{fs} = \text{interfacial area density, that is, the ratio of the area of the fluid / solid interface and the volume of the porous zone} \]
\[ T_f = \text{temperature of the fluid} \]
\[ T_s = \text{temperature of the solid medium} \]
\[ S_f^h = \text{fluid enthalpy source term} \]
\[ S_s^h = \text{solid enthalpy source term} \]

The fluid thermal conductivity \( k_f \) and the solid thermal conductivity \( k_s \) can be computed via user-defined functions.

The source term due to the non-equilibrium thermal model is represented in Equation 6.10 (p. 228) and Equation 6.11 (p. 228) by \( h_{fs} A_{fs} (T_f - T_s) \) and \( h_{fs} A_{fs} (T_s - T_f) \), respectively.

### 6.2.3.4. Treatment of Turbulence in Porous Media

ANSYS Fluent will, by default, solve the standard conservation equations for turbulence quantities in the porous medium. In this default approach, turbulence in the medium is treated as though the solid medium has no effect on the turbulence generation or dissipation rates. This assumption may be reasonable if the medium's permeability is quite large and the geometric scale of the medium does not interact with the scale of the turbulent eddies. In other instances, however, you may want to suppress the effect of turbulence in the medium.
If you are using one of the turbulence models (with the exception of the Large Eddy Simulation (LES) model), you can suppress the effect of turbulence in a porous region by enabling the **Laminar Zone** option in the Fluid Dialog Box (p. 2085). Refer to Specifying a Laminar Zone (p. 217) for details about using the **Laminar Zone** option.

### 6.2.3.5. Effect of Porosity on Transient Scalar Equations

For transient porous media calculations, the effect of porosity on the time-derivative terms is accounted for in all scalar transport equations and the continuity equation. When the effect of porosity is taken into account, the time-derivative term becomes \( \frac{\partial}{\partial t} (\gamma \rho \phi) \), where \( \phi \) is the scalar quantity \((k, c, \text{etc.})\) and \( \gamma \) is the porosity.

The effect of porosity is enabled automatically for transient calculations, and the porosity is set to 1 by default.

### 6.2.3.6. User Inputs for Porous Media

When you are modeling a porous region, the only additional inputs for the problem setup are as follows. Optional inputs are indicated as such.

1. Define the porous zone.
2. Define the porous velocity formulation in the **Cell Zone Conditions** task page. (optional)
3. Identify the fluid material flowing through the porous medium.
4. Enable reactions for the porous zone, if appropriate, and select the reaction mechanism.
5. Enable the **Relative Velocity Resistance Formulation**. By default, this option is already enabled and takes the moving porous media into consideration (as described in Including the Relative Velocity Resistance Formulation (p. 231)).
6. Set the viscous resistance coefficients \((D_{ij} \text{ in Equation 6.1 (p. 225), or } 1/\alpha \text{ in Equation 6.2 (p. 225)})\) and the inertial resistance coefficients \((C_{ij} \text{ in Equation 6.1 (p. 225), or } C_2 \text{ in Equation 6.2 (p. 225)})\), and define the direction vectors for which they apply. Alternatively, specify the coefficients for the power-law model.
7. Specify the porosity of the porous medium.
8. Specify the settings for heat transfer. (optional)
9. Set the volumetric heat generation rate in the non-solid portion of the porous medium (or any other sources, such as mass or momentum). (optional)
10. Set any fixed values for solution variables in the fluid region (optional).
11. Suppress the turbulent viscosity in the porous region, if appropriate.
12. Specify the rotation axis and/or zone motion, if relevant.

Methods for determining the resistance coefficients and/or permeability are presented below. If you choose to use the power-law approximation of the porous-media momentum source term, you will enter the coefficients \(C_0'\) and \(C_1'\) in Equation 6.3 (p. 225) instead of the resistance coefficients and flow direction.
You will set all parameters for the porous medium in the Fluid Dialog Box (p. 2085) (Figure 6.12: The Fluid Dialog Box for a Porous Zone (p. 230)), which is opened from the Cell Zone Conditions task page (as described in Setting Cell Zone and Boundary Conditions (p. 204)).

**Figure 6.12: The Fluid Dialog Box for a Porous Zone**

![Fluid Dialog Box](image)

6.2.3.6.1. Defining the Porous Zone

As mentioned in Overview (p. 201), a porous zone is modeled as a special type of fluid zone. To indicate that the fluid zone is a porous region, enable the Porous Zone option in the Fluid dialog box. The dialog box will expand to show the porous media inputs (as shown in Figure 6.12: The Fluid Dialog Box for a Porous Zone (p. 230)).

6.2.3.6.2. Defining the Porous Velocity Formulation

The Cell Zone Conditions task page contains a Porous Formulation region where you can instruct ANSYS Fluent to use either a superficial or physical velocity in the porous medium simulation. By default, the velocity is set to Superficial Velocity. For details about using the Physical Velocity formulation, see Modeling Porous Media Based on Physical Velocity (p. 243).
6.2.3.6.3. Defining the Fluid Passing Through the Porous Medium

To define the fluid that passes through the porous medium, select the appropriate fluid in the Material Name drop-down list in the Fluid Dialog Box (p. 2085). If you want to check or modify the properties of the selected material, you can click Edit... to open the Edit Material dialog box; this dialog box contains just the properties of the selected material, not the full contents of the standard Create/Edit Materials dialog box.

**Important**

If you are modeling species transport or multiphase flow, the Material Name list will not appear in the Fluid dialog box. For species calculations, the mixture material for all fluid/porous zones will be the material you specified in the Species Model Dialog Box (p. 1943). For multiphase flows, the materials are specified when you define the phases, as described in Defining the Phases for the VOF Model (p. 1296).

6.2.3.6.4. Enabling Reactions in a Porous Zone

If you are modeling species transport with reactions, you can enable reactions in a porous zone by turning on the Reaction option in the Fluid dialog box and selecting a mechanism in the Reaction Mechanism drop-down list.

If your mechanism contains wall surface reactions, you also must specify a value for the Surface-to-Volume Ratio. This value is the surface area of the pore walls per unit volume \( \frac{A}{V} \), and can be thought of as a measure of catalyst loading. With this value, ANSYS Fluent can calculate the total surface area on which the reaction takes place in each cell by multiplying \( \frac{A}{V} \) by the volume of the cell. See Defining Zone-Based Reaction Mechanisms (p. 904) for details about defining reaction mechanisms. See Wall Surface Reactions and Chemical Vapor Deposition (p. 918) for details about wall surface reactions.

6.2.3.6.5. Including the Relative Velocity Resistance Formulation

For cases involving moving meshes, dynamic meshes or moving reference frames (MRF), the Relative Velocity Resistance Formulation option allows you to better predict porous media sources. The porous media source terms are calculated using relative velocities in the porous zone. For more information, see Momentum Equations for Porous Media (p. 224). The Relative Velocity Resistance Formulation option works well for cases with moving and stationary porous media. It is turned on by default.

**Note**

In ANSYS Fluent 6.3, this option was only supported for moving mesh and MRF (with the exception of power law for modeling porous sources). Currently, this option also supports dynamic mesh and takes care of proper treatment of porous sources using power law.

6.2.3.6.6. Defining the Viscous and Inertial Resistance Coefficients

The viscous and inertial resistance coefficients are both defined in the same manner. The basic approach for defining the coefficients using a Cartesian coordinate system is to define one direction vector in 2D or two direction vectors in 3D, and then specify the viscous and/or inertial resistance coefficients in each direction. In 2D, the second direction, which is not explicitly defined, is normal to the plane defined...
by the specified direction vector and the \( z \) direction vector. In 3D, the third direction is normal to the plane defined by the two specified direction vectors. For a 3D problem, the second direction must be normal to the first. If you fail to specify two normal directions, the solver will ensure that they are normal by ignoring any component of the second direction that is in the first direction. You should therefore be certain that the first direction is correctly specified.

You can also define the viscous and/or inertial resistance coefficients in each direction using a user-defined function (UDF). The user-defined options become available in the corresponding drop-down list when the UDF has been created and loaded into ANSYS Fluent. Note that the coefficients defined in the UDF must utilize the \texttt{DEFINE_PROFILE} macro. For more information on creating and using user-defined function, see the \textit{UDF Manual}.

If you are modeling axisymmetric swirling flows, you can specify an additional direction component for the viscous and/or inertial resistance coefficients. This direction component is always tangential to the other two specified directions. This option is available for both density-based and pressure-based solvers.

In 3D, it is also possible to define the coefficients using a conical (or cylindrical) coordinate system, as described below.

---

**Important**

Note that the viscous and inertial resistance coefficients are generally based on the superficial velocity of the fluid in the porous media.

---

The procedure for defining resistance coefficients is as follows:

1. Define the direction vectors.
   
   - To use a Cartesian coordinate system, simply specify the \textbf{Direction-1 Vector} and, for 3D, the \textbf{Direction-2 Vector}. The unspecified direction will be determined as described above. These direction vectors correspond to the principle axes of the porous media.

---

**Note**

The units for the inertial resistance coefficients (\textbf{Direction-1 Vector} and \textbf{Direction-2 Vector}) is the inverse of length. Should you want to define different units, you can do so by opening the \textit{Units} dialog box and selecting \textit{resistance} from the \textit{Quantities} list.

---

For some problems in which the principal axes of the porous medium are not aligned with the coordinate axes of the domain, you may not know a priori the direction vectors of the porous medium. In such cases, the plane tool in 3D (or the line tool in 2D) can help you to determine these direction vectors.

a. “Snap” the plane tool (or the line tool) onto the boundary of the porous region. (Follow the instructions in Using the Plane Tool (p. 1591) or Using the Line Tool (p. 1587) for initializing the tool to a position on an existing surface.)

b. Rotate the axes of the tool appropriately until they are aligned with the porous medium.

c. Once the axes are aligned, click the \textbf{Update From Plane Tool} or \textbf{Update From Line Tool} button in the \textbf{Fluid} dialog box. ANSYS Fluent will automatically set the \textbf{Direction-1 Vector} to the direction of the red arrow of the tool, and (in 3D) the \textbf{Direction-2 Vector} to the direction of the green arrow.
To use a conical coordinate system (for example, for an annular, conical filter element), follow the steps below. This option is available only in 3D cases.

a. Turn on the Conical option.

b. Set the Cone Half Angle (the angle between the cone’s axis and its surface, shown in Figure 6.13: Cone Half Angle (p. 233)). To use a cylindrical coordinate system, set the Cone Half Angle to 0.

c. Specify the Cone Axis Vector and Point on Cone Axis. The cone axis is specified as being in the direction of the Cone Axis Vector (unit vector), and passing through the Point on Cone Axis. The cone axis may or may not pass through the origin of the coordinate system.

Figure 6.13: Cone Half Angle

For some problems in which the axis of the conical filter element is not aligned with the coordinate axes of the domain, you may not know a priori the direction vector of the cone axis and coordinates of a point on the cone axis. In such cases, the plane tool can help you to determine the cone axis vector and point coordinates. One method is as follows:

a. Select a boundary zone of the conical filter element that is normal to the cone axis vector in the drop-down list next to the Snap to Zone button.

b. Click the Snap to Zone button. ANSYS Fluent will automatically “snap” the plane tool onto the boundary. It will also set the Cone Axis Vector and the Point on Cone Axis. (Note that you will still have to set the Cone Half Angle yourself.)

An alternate method is as follows:

a. “Snap” the plane tool onto the boundary of the porous region. (Follow the instructions in Using the Plane Tool (p. 1591) for initializing the tool to a position on an existing surface.)

b. Rotate and translate the axes of the tool appropriately until the red arrow of the tool is pointing in the direction of the cone axis vector and the origin of the tool is on the cone axis.

c. Once the axes and origin of the tool are aligned, click the Update From Plane Tool button in the Fluid dialog box. ANSYS Fluent will automatically set the Cone Axis Vector and the Point on Cone Axis. (Note that you will still have to set the Cone Half Angle yourself.)

2. Under Viscous Resistance, specify the viscous resistance coefficient \(1/\alpha\) in each direction.

Under Inertial Resistance, specify the inertial resistance coefficient \(C_2\) in each direction. (You can scroll down with the scroll bar to view these inputs.)

For porous media cases containing highly anisotropic inertial resistances, enable Alternative Formulation under Inertial Resistance. The Alternative Formulation option provides better stability to the calculation when your porous medium is anisotropic. The pressure loss through the medium...
depends on the magnitude of the velocity vector of the ith component in the medium. Using the formulation of Equation 6.6 (p. 226) yields the expression below:

\[ S_i = \frac{1}{2} \rho C_i |v_i| v_i \]  

(6.12)

Whether or not you use the Alternative Formulation option depends on how well you can fit your experimentally determined pressure drop data to the ANSYS Fluent model. For example, if the flow through the medium is aligned with the mesh in your ANSYS Fluent model, then it will not make a difference whether or not you use the formulation.

For more information about simulations involving highly anisotropic porous media, see Solution Strategies for Porous Media (p. 245).

**Important**

Note that the alternative formulation is compatible only with the pressure-based solver.

If you are using the Conical specification method, Direction-1 is the tangential direction of the cone, Direction-2 is the normal to the cone surface (radial \( r \) direction for a cylinder), and Direction-3 is the circumferential \( \theta \) direction.

In 3D there are three possible categories of coefficients, and in 2D there are two:

- In the isotropic case, the resistance coefficients in all directions are the same (for example, a sponge). For an isotropic case, you must explicitly set the resistance coefficients in each direction to the same value.

- When (in 3D) the coefficients in two directions are the same and those in the third direction are different or (in 2D) the coefficients in the two directions are different, you must be careful to specify the coefficients properly for each direction. For example, if you had a porous region consisting of cylindrical straws with small holes in them positioned parallel to the flow direction, the flow would pass easily through the straws, but the flow in the other two directions (through the small holes) would be very little. If you had a plane of flat plates perpendicular to the flow direction, the flow would not pass through them at all; it would instead move in the other two directions.

- In 3D the third possible case is one in which all three coefficients are different. For example, if the porous region consisted of a plane of irregularly-spaced objects (for example, pins), the movement of flow between the blockages would be different in each direction. You would therefore need to specify different coefficients in each direction.

Methods for deriving viscous and inertial loss coefficients are described in the sections that follow.

6.2.3.6.7. Deriving Porous Media Inputs Based on Superficial Velocity, Using a Known Pressure Loss

When you use the porous media model, you must keep in mind that the porous cells in ANSYS Fluent are 100% open, and that the values that you specify for \( 1/\alpha_{ij} \) and/or \( C_{2,ij} \) must be based on this assumption. Suppose, however, that you know how the pressure drop varies with the velocity through the actual device, which is only partially open to flow. The following exercise is designed to show you how to compute a value for \( C_2 \) which is appropriate for the ANSYS Fluent model.
Consider a perforated plate that has 25% area open to flow. The pressure drop through the plate is known to be 0.5 times the dynamic head in the plate. The loss factor, $K_L$, defined as

$$\Delta p = K_L \left( \frac{1}{2} \rho v^2 \right)_{25\% \text{ open}}$$  \hspace{1cm} (6.13)$$

is therefore 0.5, based on the actual fluid velocity in the plate, that is, the velocity through the 25% open area. To compute an appropriate value for $C_2$, note that in the ANSYS Fluent model:

1. The velocity through the perforated plate assumes that the plate is 100% open.
2. The loss coefficient must be converted into dynamic head loss per unit length of the porous region.

Noting item 1, the first step is to compute an adjusted loss factor, $K_L'$, which would be based on the velocity of a 100% open area:

$$\Delta p = K_L' \left( \frac{1}{2} \rho v^2 \right)_{100\% \text{ open}}$$  \hspace{1cm} (6.14)$$

or, noting that for the same flow rate, $v_{25\% \text{ open}} = 4 \times v_{100\% \text{ open}}$

$$K_L' = K_L \times \frac{v_{25\% \text{ open}}}{v_{100\% \text{ open}}} = 0.5 \times \left( \frac{4}{1} \right)^2 = 8$$  \hspace{1cm} (6.15)$$

The adjusted loss factor has a value of 8. Noting item 2, you must now convert this into a loss coefficient per unit thickness of the perforated plate. Assume that the plate has a thickness of 1.0 mm ($10^{-3}$ m). The inertial loss factor would then be

$$C_2 = \frac{K_L'}{\text{thickness}} = \frac{8}{10^{-3}} = 8000 \text{ m}^{-1}$$  \hspace{1cm} (6.16)$$

Note that, for anisotropic media, this information must be computed for each of the 2 (or 3) coordinate directions.

### 6.2.3.6.8. Using the Ergun Equation to Derive Porous Media Inputs for a Packed Bed

As a second example, consider the modeling of a packed bed. In turbulent flows, packed beds are modeled using both a permeability and an inertial loss coefficient. One technique for deriving the appropriate constants involves the use of the Ergun equation [23] (p. 2558), a semi-empirical correlation applicable over a wide range of Reynolds numbers and for many types of packing:

$$\frac{\Delta p}{L} = \frac{150 \mu}{D_p^2} \left( 1 - \varepsilon \right)^2 v_\infty + \frac{1.75 \rho}{D_p} \left( 1 - \varepsilon \right)^{\frac{3}{2}} v_\infty^2$$  \hspace{1cm} (6.17)$$

When modeling laminar flow through a packed bed, the second term in the above equation may be dropped, resulting in the Blake-Kozeny equation [23] (p. 2558):

$$\frac{\Delta p}{L} = \frac{150 \mu}{D_p^2} \left( 1 - \varepsilon \right)^2 v_\infty$$  \hspace{1cm} (6.18)$$

In these equations, $\mu$ is the viscosity, $D_p$ is the mean particle diameter, $L$ is the bed depth, and $\varepsilon$ is the void fraction, defined as the volume of voids divided by the volume of the packed bed region. Comparing...
Equation 6.4 (p. 225) and Equation 6.6 (p. 226) with Equation 6.17 (p. 235), the permeability and inertial loss coefficient in each component direction may be identified as

$$\alpha = \frac{D_p^2}{150} \frac{\varepsilon^3}{(1-\varepsilon)^2}$$

(6.19)

and

$$C_2 = \frac{3.5}{D_p} \frac{(1-\varepsilon)}{\varepsilon^3}$$

(6.20)

### 6.2.3.6.9. Using an Empirical Equation to Derive Porous Media Inputs for Turbulent Flow Through a Perforated Plate

As a third example we will take the equation of Van Winkle et al. [71] (p. 2560) [95] (p. 2562) and show how porous media inputs can be calculated for pressure loss through a perforated plate with square-edged holes.

The expression, which is claimed by the authors to apply for turbulent flow through square-edged holes on an equilateral triangular spacing, is

$$\dot{m} = C A_f \left( 2 \rho \Delta p \right) \frac{1}{1 - \left( A_f/A_p \right)^2}$$

(6.21)

where

- $\dot{m}$ = mass flow rate through the plate
- $A_f$ = the free area or total area of the holes
- $A_p$ = the area of the plate (solid and holes)
- $C$ = a coefficient that has been tabulated for various Reynolds-number ranges and for various $D/t$
- $D/t$ = the ratio of hole diameter to plate thickness

for $t/D > 1.6$ and for $Re > 4000$ the coefficient $C$ takes a value of approximately 0.98, where the Reynolds number is based on hole diameter and velocity in the holes.

Rearranging Equation 6.21 (p. 236), making use of the relationship

$$\dot{m} = \rho v A_p$$

(6.22)

and dividing by the plate thickness, $\Delta x = t$, we obtain

$$\frac{\Delta p}{\Delta x} = \left( \frac{1}{2} \rho v^2 \right) \frac{1}{C^2} \frac{\left( A_f/A_p \right)^2 - 1}{t}$$

(6.23)

where $v$ is the superficial velocity (not the velocity in the holes). Comparing with Equation 6.6 (p. 226) is seen that, for the direction normal to the plate, the constant $C_2$ can be calculated from

$$C_2 = \frac{1}{C^2} \frac{(A_f/A_p)^2 - 1}{t}$$

(6.24)
6.2.3.6.10. Using Tabulated Data to Derive Porous Media Inputs for Laminar Flow Through a Fibrous Mat

Consider the problem of laminar flow through a mat or filter pad which is made up of randomly-oriented fibers of glass wool. As an alternative to the Blake-Kozeny equation (Equation 6.18 (p. 235)) we might choose to employ tabulated experimental data. Such data is available for many types of fiber [39] (p. 2559).

<table>
<thead>
<tr>
<th>Volume Fraction of Solid Material</th>
<th>Dimensionless Permeability $B$ of Glass Wool</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.26</td>
<td>0.25</td>
</tr>
<tr>
<td>0.258</td>
<td>0.26</td>
</tr>
<tr>
<td>0.221</td>
<td>0.40</td>
</tr>
<tr>
<td>0.218</td>
<td>0.41</td>
</tr>
<tr>
<td>0.172</td>
<td>0.80</td>
</tr>
</tbody>
</table>

where $B = \alpha / \alpha^2$ and $\alpha$ is the fiber diameter. $\alpha$, for use in Equation 6.4 (p. 225), is easily computed for a given fiber diameter and volume fraction.

6.2.3.6.11. Deriving the Porous Coefficients Based on Experimental Pressure and Velocity Data

Experimental data that is available in the form of pressure drop against velocity through the porous component, can be extrapolated to determine the coefficients for the porous media. To effect a pressure drop across a porous medium of thickness, $\Delta n$, the coefficients of the porous media are determined in the manner described below.

If the experimental data is:

<table>
<thead>
<tr>
<th>Velocity (m/s)</th>
<th>Pressure Drop (Pa)</th>
</tr>
</thead>
<tbody>
<tr>
<td>20.0</td>
<td>197.8</td>
</tr>
<tr>
<td>50.0</td>
<td>948.1</td>
</tr>
<tr>
<td>80.0</td>
<td>2102.5</td>
</tr>
<tr>
<td>110.0</td>
<td>3832.9</td>
</tr>
</tbody>
</table>

then an $xy$ curve can be plotted to create a trendline through these points yielding the following equation

$$\Delta p = 0.27394v^2 + 4.68816v$$

(6.25)

where $\Delta p$ is the pressure drop and $v$ is the velocity.

**Important**

Although the best fit curve may yield negative coefficients, it should be avoided when using the porous media model in ANSYS Fluent.

Note that a simplified version of the momentum equation, relating the pressure drop to the source term, can be expressed as

$$\nabla p = S_l$$

(6.26)
or
\[ \Delta p = -S_l \Delta n \]  
(6.27)

Hence, comparing Equation 6.25 (p. 237) to Equation 6.2 (p. 225), yields the following curve coefficients:
\[ 0.27394 = \frac{1}{2} \rho \Delta n \]  
(6.28)

with \( \rho = 1.225 \text{ kg/m}^3 \), and a porous media thickness, \( \Delta n \), assumed to be 1 m in this example, the inertial resistance factor, \( C_2 = 0.447 \).

Likewise,
\[ 4.68816 = \frac{\mu}{\alpha} \Delta n \]  
(6.29)

with \( \mu = 1.7894 \times 10^{-5} \), the viscous inertial resistance factor, \( \frac{1}{\alpha} = 261996 \).

---

**Important**

Note that this same technique can be applied to the porous jump boundary condition. Similar to the case of the porous media, you have to take into account the thickness of the medium \( \Delta n \). Your experimental data can be plotted in an \( xy \) curve, yielding an equation that is equivalent to Equation 6.117 (p. 350). From there, you can determine the permeability \( \alpha \) and the pressure jump coefficient \( C_2 \).

---

**6.2.3.6.12. Using the Power-Law Model**

If you choose to use the power-law approximation of the porous-media momentum source term (Equation 6.3 (p. 225)), the only inputs required are the coefficients \( C_0 \) and \( C_1 \). Under Power Law Model in the Fluid dialog box, enter the values for \( C_0 \) and \( C_1 \). Note that the power-law model can be used in conjunction with the Darcy and inertia models.

\( C_0 \) must be in SI units, consistent with the value of \( C_1 \).

**6.2.3.6.13. Defining Porosity**

To define the porosity, scroll down below the resistance inputs in the Fluid dialog box, and set the Porosity under Fluid Porosity. Note that the value of the Porosity must be in the range of 0–1; furthermore, the lower and upper limits (that is, 0 and 1, respectively) are not allowed for the non-equilibrium thermal model.

You can also define the porosity using a user-defined function (UDF). The user-defined option becomes available in the corresponding drop-down list when the UDF has been created and loaded into ANSYS Fluent. Note that the porosity defined in the UDF must utilize the \textsc{DEFINE_PROFILE} macro. For more information on creating and using user-defined functions, see the separate UDF Manual.

The porosity, \( \gamma \), is the volume fraction of fluid within the porous region (that is, the open volume fraction of the medium). The porosity is used in the prediction of heat transfer in the medium, as described in Treatment of the Energy Equation in Porous Media (p. 226), and in the time-derivative term in the scalar transport equations for unsteady flow, as described in Effect of Porosity on Transient Scalar Equations (p. 229). It also impacts the calculation of reaction source terms and body forces in the medium.
These sources will be proportional to the fluid volume in the medium. If you want to represent the medium as completely open (no effect of the solid medium), you should set the porosity equal to 1.0 (the default). When the porosity is equal to 1.0, the solid portion of the medium will have no impact on heat transfer or thermal/reaction source terms in the medium.

6.2.3.6.14. Specifying the Heat Transfer Settings

You can model heat transfer in the porous material, with or without the assumption of thermal equilibrium between the medium and the fluid flow. Note that heat transfer is not available for inviscid flow.

6.2.3.6.14.1. Equilibrium Thermal Model

To specify that the porous medium and the fluid flow are in thermal equilibrium, scroll down below the resistance inputs in the Fluid dialog box to the Heat Transfer Settings group box and select Equilibrium from the Thermal Model list (this is the default selection). Then you must specify the material contained in the porous medium by selecting the appropriate solid in the Solid Material Name drop-down list.

If you want to check or modify the properties of the selected material, you can click Edit... to open the Edit Material dialog box; this dialog box contains just the properties of the selected material, not the full contents of the standard Create/Edit Materials dialog box. You can define the Thermal Conductivity of the porous material using a user-defined function (UDF), in order to define a non-isotropic thermal conductivity. The user-defined option becomes available in the corresponding drop-down list when the UDF has been created and loaded into ANSYS Fluent. Note that the non-isotropic thermal conductivity defined in the UDF must utilize the DEFINE_PROPERTY macro. For more information on creating and using user-defined function, see the separate UDF Manual.

6.2.3.6.14.2. Non-Equilibrium Thermal Model

Note

The non-equilibrium thermal model is incompatible with the density based solver.

The assumption of thermal equilibrium between the solid medium and the fluid flow is not appropriate for all simulations, as the presence of different geometric length scales (for example, pore sizes) and physical properties of solid and liquid phases may result in local temperature differences between the phases. Examples of when a non-equilibrium thermal model may be suitable include the simulation of light-off for exhaust after-treatment, fuel cells, catalytic converters, etc.

The non-equilibrium thermal model available for porous media in ANSYS Fluent is based on a dual cell approach. This approach is referred to as “dual cell” because it involves a second solid cell zone that overlaps (that is, is spatially coincident with) the porous fluid zone; the two zones are solved simultaneously and are coupled only through heat transfer. ANSYS Fluent can automatically create a solid zone for you that is a duplicate of the porous fluid zone, as long as the zone does not have non-conformal interfaces. When the zone does have non-conformal interfaces, you must create a duplicate cell zone manually using the mesh/modify-zones/copy-move-cell-zone text command before you enable the non-equilibrium thermal model, or make sure that the mesh you read contains two cell zones in the region where the porous medium will be defined. You should ensure that the duplicate zone is
defined as a solid zone, and that the two zones have similar levels of mesh refinement (as one-to-one mapping will be employed between the cell centroids of the fluid zone and the solid zone).

**Important**

When setting up both the porous fluid zone and the overlapping solid zone, note that the non-equilibrium thermal model is not supported for zones that undergo (or are adjacent to zones that undergo) changes to the geometry or mesh, such as dynamic mesh zones or zones that undergo adaption, utilize the mesh morpher/optimizer, or are involved in fluid-structure interaction (FSI) applications.

The instructions that follow assume you have already performed steps 1–7 in User Inputs for Porous Media (p. 229). Before you enable the non-equilibrium thermal model, click OK in the Fluid dialog box, in order to save your settings in the Porous Zone tab; note that if you do not save your settings, they will be reset to the default values when you enable the non-equilibrium thermal model. Then reopen the Fluid dialog box and scroll down below the resistance inputs in the Porous Zone tab. Select Non-Equilibrium from the Thermal Model list in the Heat Transfer Settings group box (see Figure 6.14: The Heat Transfer Settings Group Box of the Fluid Dialog Box (p. 241)); this will enable the dual cell approach and display the associated GUI input controls. If a solid zone that is spatially coincident with the porous fluid zone does not already exist, use the Question dialog box that opens to automatically create one. The name of the newly created solid cell zone will then be displayed in the Solid Zone text box of the Fluid dialog box.

**Important**

Note that the Non-Equilibrium option button is not available if a radiation and/or multiphase model is enabled, as such a combination is not supported.
Next, define $A_{fS}$ and $h_{fS}$ (as described in Non-Equilibrium Thermal Model Equations (p. 227)) for **Interfacial Area Density** and **Heat Transfer Coefficient**, respectively; you can define these settings as a Constant, a New Input Parameter..., or as a user-defined function. The *user-defined* option becomes available in the corresponding drop-down list when the UDF has been created and loaded into ANSYS Fluent. Note that the UDF must utilize the DEFINE_PROFILE macro. For more information on creating and using user-defined functions, see the separate UDF Manual.

When you are finished setting up the porous fluid zone, you should verify that the solid zone created in the previous step has the appropriate settings. Note the name of the zone displayed in the **Solid Zone** text box of the **Heat Transfer Settings** group box (see Figure 6.14: The Heat Transfer Settings Group Box of the Fluid Dialog Box (p. 241)), and then double-click that zone in the **Zone** list of the **Cell Zone Conditions** task page to open the **Solid** dialog box. Then, verify that an appropriate selection is made for **Material Name**. If you want to check or modify the properties of the selected material, you
can click **Edit...** to open the **Edit Material** dialog box; this dialog box contains just the properties of the selected material, not the full contents of the standard **Create/Edit Materials** dialog box. You can define the **Thermal Conductivity** of the solid material using a user-defined function (UDF), in order to define a non-isotropic thermal conductivity. The user-defined option becomes available in the corresponding drop-down list when the UDF has been created and loaded into ANSYS Fluent. Note that the non-isotropic thermal conductivity defined in the UDF must utilize the **DEFINE_PROPERTY** macro. For more information on creating and using user-defined functions, see the separate **UDF Manual**.

Note that when postprocessing simulations that utilize the non-equilibrium thermal model, you can use the **Non-Equilibrium Thermal Model Source** variable in the **Temperature...** category to display the scaled value of thermal conductivity for the fluid zone \((\gamma k_F)\) or for the overlapping solid zone \((1 - \gamma) k_S\), where \(\gamma\) is the porosity, \(k_F\) is the fluid phase thermal conductivity (including the turbulent contribution, \(k_{\tau}\)), and \(k_S\) is the solid medium thermal conductivity. Furthermore, attention must be paid to the fact that there are overlapping cell zones (that is, a fluid and a solid zone) in the porous region. For example:

- When creating an isosurface and making selections from the **From Zones** selection list of the **Iso-Surface** dialog box, you should never select both the porous fluid zone and the overlapping solid zone at the same time. Note that if no selections are made in this list, then all the cell zones are selected.

- When making selections from the **Surfaces** list of the **Contours** dialog box, you should not select a surface that is associated with the porous fluid zone and a surface associated with the overlapping solid zone at the same time, if those surfaces are spatially coincident.

### 6.2.3.6.15. Defining Sources

If you want to include effects of the heat generated by the porous medium in the energy equation, enable the **Source Terms** option and set a non-zero **Energy** source. The solver will compute the heat generated by the porous region by multiplying this value by the total volume of the cells comprising the porous zone. You may also define sources of mass, momentum, turbulence, species, or other scalar quantities, as described in **Defining Mass, Momentum, Energy, and Other Sources** (p. 251).

### 6.2.3.6.16. Defining Fixed Values

If you want to fix the value of one or more variables in the fluid region of the zone, rather than computing them during the calculation, you can do so by enabling the **Fixed Values** option. See **Fixing the Values of Variables** (p. 247) for details.

### 6.2.3.6.17. Suppressing the Turbulent Viscosity in the Porous Region

As discussed in **Treatment of Turbulence in Porous Media** (p. 228), turbulence will be computed in the porous region just as in the bulk fluid flow. If you are using one of the turbulence models (other than the Large Eddy Simulation model) and you want the turbulence generation to be zero in the porous zone, turn on the **Laminar Zone** option in the **Fluid** dialog box. Refer to **Specifying a Laminar Zone** (p. 217) for more information about suppressing turbulence generation.

### 6.2.3.6.18. Specifying the Rotation Axis and Defining Zone Motion

Inputs for the rotation axis and zone motion are the same as for a standard fluid zone. See **Inputs for Fluid Zones** (p. 216) for details.
6.2.3.7. Modeling Porous Media Based on Physical Velocity

As stated in Limitations and Assumptions of the Porous Media Model (p. 224), by default ANSYS Fluent calculates the superficial velocity based on volumetric flow rate. The superficial velocity in the governing equations can be represented as

\[
\vec{V}_{\text{superficial}} = \gamma \vec{V}_{\text{physical}}
\]

(6.30)

where \( \gamma \) is the porosity of the media defined as the ratio of the volume occupied by the fluid to the total volume.

The superficial velocity values within the porous region remain the same as those outside of the porous region, and porosity is not taken into account in the differential terms of the transport equations. This limits the accuracy of the porous model in cases where there should be an increase in velocity throughout the porous region, and does not yield accurate results when velocity values and gradients are important. For more accurate simulations of porous media flows, it becomes necessary to solve for the true, or physical, velocity throughout the flowfield rather than the superficial velocity, as well as to include porosity in all terms of the transport equations.

ANSYS Fluent allows the calculation of the physical velocity using the Porous Formulation, available in the Cell Zone Conditions task page. By default, the Superficial Velocity option is turned on.

6.2.3.7.1. Single Phase Porous Media

Using the physical velocity formulation, and assuming a general scalar \( \phi \), the governing equation in an isotropic porous media has the following form:

\[
\frac{\partial (\gamma \rho \phi)}{\partial t} + \nabla \cdot (\gamma \rho \vec{V} \phi) = \nabla \cdot (\gamma s \nabla \phi) + \gamma S_\phi
\]

(6.31)

Assuming isotropic porosity and single phase flow, the volume-averaged mass and momentum conservation equations are as follows:

\[
\frac{\partial (\gamma \rho)}{\partial t} + \nabla \cdot (\gamma \rho \vec{V}) = 0
\]

(6.32)

\[
\frac{\partial (\gamma \rho \vec{V})}{\partial t} + \nabla \cdot (\gamma \rho \vec{V} \vec{V}) = -\gamma \nabla p + \nabla \cdot (\gamma \vec{t}) + \gamma \vec{B} \cdot \left( \frac{\gamma^2 \mu}{K} \vec{V} + \frac{\gamma^3 C_2}{2 \rho} |\vec{V}| \vec{V} \right)
\]

(6.33)

The last term in Equation 6.33 (p. 243) represents the viscous and inertial drag forces imposed by the pore walls on the fluid.

---

**Important**

Note that even when you solve for the physical velocity in Equation 6.33 (p. 243), the two resistance coefficients can still be derived using the superficial velocity as given in Defining the Viscous and Inertial Resistance Coefficients (p. 231). ANSYS Fluent assumes that the inputs for these resistance coefficients are based upon well-established empirical correlations that are usually based on superficial velocity. Therefore, ANSYS Fluent automatically converts the
inputs for the resistance coefficients into those that are compatible with the physical velocity formulation.

**Important**

Note that the inlet mass flow is also calculated from the superficial velocity. Therefore, for the same mass flow rate at the inlet and the same resistance coefficients, for either the physical or superficial velocity formulation you should obtain the same pressure drop across the porous media zone.

### 6.2.3.7.2. Multiphase Porous Media

You can simulate porous media multiphase flows using the **Physical Velocity Porous Formulation** to solve the true or physical velocity field throughout the entire flow field, including both porous and non-porous regions. In this approach, assuming a general scalar in the \( q^{th} \) phase, \( \phi_q \), the governing equation in an isotropic porous medium takes on the following form:

\[
\frac{\partial}{\partial t} \left( \gamma \alpha_q \rho_q \phi_q \right) + \nabla \cdot \left( \gamma \alpha_q \rho_q \vec{v}_q \phi_q \right) = \nabla \cdot \left( \gamma \Gamma_q \nabla \phi_q \right) + \gamma S_{\phi,q} \tag{6.34}
\]

Here \( \gamma \) is the porosity, which may vary with time and space; \( \rho_q \) is the phase density; \( \alpha_q \) is the volume fraction; \( \vec{v}_q \) is the phase velocity vector; \( S_{\phi,q} \) is the source term; and \( \Gamma_q \) is the diffusion coefficient.

The general scalar equation Equation 6.34 (p. 244) applies to all other transport equations in the Eulerian multiphase model, such as the granular phase momentum and energy equations, turbulence modeling equations, and the species transport equations.

Assuming isotropic porosity and multiphase flows, the governing equations in the \( q^{th} \) phase, Equation 17.152, Equation 17.153, and Equation 17.156 in the Theory Guide take the general forms described below.

#### 6.2.3.7.2.1. The Continuity Equation

\[
\frac{\partial}{\partial t} \left( \gamma \alpha_q \rho_q \right) + \nabla \cdot \left( \gamma \alpha_q \rho_q \vec{v}_q \right) = \gamma \sum_{p=1}^{n} \left( \dot{m}_{pq} - \dot{m}_{qp} \right) + \gamma S_q \tag{6.35}
\]

#### 6.2.3.7.2.2. The Momentum Equation

\[
\frac{\partial}{\partial t} \left( \gamma \alpha_q \rho_q \vec{v}_q \right) + \nabla \cdot \left( \gamma \alpha_q \rho_q \vec{v}_q \vec{v}_q \right) = -\gamma \alpha_q \nabla p + \nabla \cdot \left( \gamma \vec{t}_q \right) + \gamma \alpha_q \rho_q \vec{g} + \gamma \sum_{p=1}^{n} \left( \bar{R}_{pq} + \dot{m}_{pq} \vec{v}_p - \dot{m}_{qp} \vec{v}_q \right) + \gamma \left( \bar{F}_q + \bar{F}_{\text{lifL}},q + \bar{F}_{\text{vm}},q \right) - \alpha_q \left( \frac{\gamma^2 \mu}{K_q} \vec{v}_q + \frac{\gamma^3 C_2.q \rho_q \vec{v}_q}{2} \right) \tag{6.36}
\]
where the last term in Equation 6.36 (p. 244) is the momentum resistance (sink) source in a porous medium. It consists of two parts: a viscous loss term, and an inertial loss term. The parameter \(K\) is the permeability, and \(C_2\) is the inertial resistance factor. Both \(K\) and \(C_2\) are functions of \((I - \gamma)\). When \(\gamma = 1\), the flow is non-porous and the two loss terms disappear. Details about the user inputs related to the momentum resistance sources can be found in User Inputs for Porous Media (p. 229).

### 6.2.3.7.2.3. The Energy Equation

\[
\frac{\partial}{\partial t} \left( \gamma \alpha q \rho_q h_q \right) + \nabla \cdot \left( \gamma \alpha q \rho_q \vec{v}_q h_q \right) = -\gamma \alpha q \frac{\partial p_q}{\partial t} + \gamma \nabla \vec{v}_q \cdot \nabla \left( \gamma \vec{q}_q \right) + \gamma S_q + \gamma \sum_{p=1}^{n} \left( Q_{pq} + m_{pq} h_{pq} - \dot{m}_{pq} h_{pq} \right) + Q_{sp}
\]

(6.37)

where \(Q_{sp}\) is the heat transfer between the solids surface and the phase \(q\) in a porous medium. Assuming only convective heat transfer, we then have

\[
Q_{sp} = (1 - \gamma) \alpha_q h_q,_{eff} \left( T_s - T_q \right)
\]

(6.38)

where \(h_q,_{eff}\) is the effective convective heat transfer coefficient, and \(T_s\) is the solids surface temperature in the porous medium. It is governed by the heat conduction equation:

\[
\frac{\partial}{\partial t} \left( \rho_s h_s \right) + \nabla \cdot \left( \overline{\nabla} \rho_s h_s \right) = \nabla \cdot \left( k_s \nabla T \right) - \sum_{p=1}^{n} Q_{sp}
\]

(6.39)

Equation 6.39 (p. 245) can be solved as a user-defined scalar (UDS) equation, as described in User-Defined Scalar (UDS) Transport Equations (p. 505). By default, ANSYS Fluent assumes that the overall heat transfer between the multiphase fluid and the solids is in equilibrium. Therefore, instead of solving Equation 6.39 (p. 245) to obtain the solids surface temperature, we have

\[
\sum_{p=1}^{n} Q_{sp} = 0
\]

(6.40)

and then

\[
T_s = \frac{\sum_{p=1}^{n} \alpha_p h_{p,_{eff}} T_p}{\sum_{p=1}^{n} \alpha_p h_{p,_{eff}}}
\]

(6.41)

### 6.2.3.8. Solution Strategies for Porous Media

In general, you can use the standard solution procedures and solution parameter settings when your ANSYS Fluent model includes porous media. You may find, however, that the rate of convergence slows when you define a porous region through which the pressure drop is relatively large in the flow direction (for example, the permeability, \(\alpha\), is low or the inertial factor, \(C_2\), is large). This slow convergence can occur because the porous media pressure drop appears as a momentum source term—yielding a loss of diagonal dominance—in the matrix of equations solved. The best remedy for poor convergence of a problem involving a porous medium is to supply a good initial guess for the pressure drop across the medium.
Similarly, **Standard Initialization** is the recommended initialization method for porous media simulations. The default **Hybrid Initialization** method does not account for the porous media properties, and depending on boundary conditions, may produce an unrealistic initial velocity field. For porous media simulations, the **Hybrid Initialization** method should only be used with the **Maintain Constant Velocity Magnitude** option.

Another possible way to deal with poor convergence is to temporarily disable the porous media model (by turning off the **Porous Zone** option in the Fluid Dialog Box (p. 2085)) and obtain an initial flow field without the effect of the porous region. With the porous media model turned off, ANSYS Fluent will treat the porous zone as a fluid zone and calculate the flow field accordingly. Once an initial solution is obtained, or the calculation is proceeding steadily to convergence, you can enable the porous media model and continue the calculation with the porous region included. (This method is not recommended for porous media with high resistance.)

Simulations involving highly anisotropic porous media may, at times, pose convergence troubles. You can address these issues by limiting the anisotropy of the porous media coefficients ($1/a_{ij}$ and $C_{2,i,j}$) to two or three orders of magnitude. Even if the medium’s resistance in one direction is infinite, you do not need to set the resistance in that direction to be greater than 1000 times the resistance in the primary flow direction.

### 6.2.3.9. Postprocessing for Porous Media

The impact of a porous region on the flow field can be determined by examining either velocity components or pressure values. Graphical plots (including XY plots and contour or vector plots) or alphanumeric reports of the following variables/functions may be of interest:

- **X, Y, Z Velocity** (in the **Velocity...** category)
- **Static Pressure** (in the **Pressure...** category)

These variables are contained in the specified categories of the variable selection drop-down list that appears in postprocessing dialog boxes.

Note that thermal reporting in the porous region is defined as follows:

$$k_{\text{eff}} = \gamma k_f + (1 - \gamma) k_s$$  \hspace{1cm} (6.42)

where

- $\gamma$ = porosity of the medium
- $k_f$ = fluid phase thermal conductivity (including the turbulent contribution, $k_f$)
\[ k_s = \text{solid medium thermal conductivity} \]

**Important**

For porous media involving surface reactions, you can display/report the surface reaction rates using the \textbf{Arrhenius Rate of Reaction-n} in the \textbf{Reactions...} category of the variable selection drop-down list.

**Important**

Special care must be taken when postprocessing a porous media simulation that utilizes the non-equilibrium thermal model. See \textbf{Non-Equilibrium Thermal Model (p. 239)} for details.

### 6.2.4. Fixing the Values of Variables

The option to fix values of variables in ANSYS Fluent allows you to set the value of one or more variables in a fluid or solid zone, essentially setting a boundary condition for the variables within the cells of the zone. When a variable is fixed in a given cell, the transport equation for that variable is not solved in the cell (and the cell is not included when the residual sum is computed for that variable). The fixed value is used for the calculation of face fluxes between the cell and its neighbors. The result is a smooth transition between the fixed value of a variable and the values at the neighboring cells.

**Important**

You can fix values for temperature and species mass fractions only if you are using the pressure-based solver. You can fix values for velocity components only if you are using the pressure-based segregated solver. (Refer to \textbf{Pressure-Based Solver} in the \textbf{Theory Guide} for information about the pressure-based segregated solver.)

#### 6.2.4.1. Overview of Fixing the Value of a Variable

The ability to fix the value of a variable has a wide range of applications. The velocity fixing method is often used to model the flow in stirred tanks. This approach provides an alternative to the use of a moving reference frame (solution in the reference frame of the blade) and can be used to model baffled tanks. In both 2D and 3D geometries, a fluid cell zone may be used in the impeller regions, and velocity components can be fixed based on measured data.

Although the actual impeller geometry can be modeled and the flow pattern calculated using the sliding mesh model, experimental data for the velocity profile in the outflow region are available for many impeller types. If you do not need to know the details of the flow around the blades for your problem, you can model the impeller by fixing the experimentally-obtained liquid velocities in its outflow zone. The velocities in the rest of the vessel can then be calculated using this fixed velocity profile as a boundary condition. \textbf{Figure 6.15: Fixing Values for the Flow in a Stirred Tank (p. 248)} shows an example of how this method is used to model the flow pattern created by a disk-turbine in an axisymmetric stirred vessel.
6.2.4.1.1. Variables That Can Be Fixed

The variables that can be fixed include velocity components (pressure-based segregated solver only), turbulence quantities, temperature (pressure-based solver only), enthalpy, species mass fractions (pressure-based solver only), and user-defined scalars. For turbulence quantities, different values can be set depending on your choice of turbulence model. You can fix the value of the temperature in a fluid or solid zone if you are solving the energy equation. If you are using the non-premixed combustion model, you can fix the enthalpy in a fluid zone. If you have more than one species in your model, you can specify fixed values for the species mass fractions for each individual species except the last one you defined. See the UDF Manual for details about defining user-defined scalars.

If you are using the Eulerian multiphase model, you can fix the values of velocity components and (depending on which multiphase turbulence model you are using) turbulence quantities on a per-phase basis. See Eulerian Model (p. 1264) for details about setting boundary conditions for Eulerian multiphase calculations.

6.2.4.2. Procedure for Fixing Values of Variables in a Zone

To fix the values of one or more variables in a cell zone, follow these steps (remembering to use only SI units):

1. **Release 15.0 - © SAS IP, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.**
1. In the Fluid Dialog Box (p. 2085) or Solid Dialog Box (p. 2092), turn on the Fixed Values option.

2. Fix the values for the appropriate variables, noting the comments below.

   • To specify a constant value for a variable, choose constant in the drop-down list next to the relevant field and then enter the constant value in the field.

   • To specify a non-constant value for a variable, you can use a profile (see Profiles (p. 377)) or a user-defined function for a profile (see the UDF Manual). Select the appropriate profile or UDF in the drop-down list next to the relevant field.

   If you specify a radial-type profile (see Profile Specification Types (p. 377)) for temperature, enthalpy, species mass/mole fractions, or turbulence quantities for the \( k-\varepsilon \), Spalart-Allmaras, or \( k-\omega \) model, the local coordinate system upon which the radial profile is based is defined by the Rotation-Axis Origin and Rotation-Axis Direction for the fluid zone. See Specifying the Rotation Axis (p. 218) for information about setting these parameters. (Note that it is acceptable to specify the rotation axis and direction for a non-rotating zone. This will not cause the zone to rotate; it will not rotate unless it has been explicitly defined as a moving zone.)

   • If you do not want to fix the value for a variable, choose (or keep) none in the drop-down list next to the relevant field. This is the default for all variables.

6.2.4.2.1. Fixing Velocity Components

To fix the velocity components, you can specify X, Y, and (in 3D) Z Velocity values, or, for axisymmetric cases, Axial, Radial, and (for axisymmetric swirl) Swirl Velocity values. The units for a fixed velocity are m/s.

For 3D cases, you can choose to specify cylindrical velocity components instead of Cartesian components. Turn on the Local Coordinate System For Fixed Velocities option, and then specify the Axial, Radial, and/or Tangential Velocity values. The local coordinate system is defined by the Rotation-Axis Origin and Rotation-Axis Direction for the fluid zone. See Specifying the Rotation Axis (p. 218) for information about setting these parameters. (Note that it is acceptable to specify the rotation axis and direction for a non-rotating zone. This will not cause the zone to rotate; it will not rotate unless it has been explicitly defined as a moving zone.)

---

Important

You can fix values for velocity components only if you are using the pressure-based segregated solver. (Refer to Pressure-Based Solver in the Theory Guide for information about the pressure-based segregated solver.)

---

6.2.4.2.2. Fixing Temperature and Enthalpy

If you are solving the energy equation, you can fix the temperature in a zone by specifying the value of the Temperature. The units for a fixed temperature are K.

If you are using the non-premixed combustion model, you can fix the enthalpy in a zone by specifying the value of the Enthalpy. The units for a fixed enthalpy are J/kg.
If you specify a radial-type profile (see Profile Specification Types (p. 377)) for temperature or enthalpy, the local coordinate system upon which the radial profile is based is defined by the Rotation-Axis Origin and Rotation-Axis Direction for the fluid zone. See above for details.

**Important**

You can fix the value of temperature only if you are using the pressure-based solver.

### 6.2.4.2.3. Fixing Species Mass Fractions

If you are using the species transport model, you can fix the values of the species mass fractions for individual species. ANSYS Fluent allows you to fix the species mass fraction for each species (for example, h2, o2) except the last one you defined.

If you specify a radial-type profile (see Profile Specification Types (p. 377)) for a species mass fraction, the local coordinate system upon which the radial profile is based is defined by the Rotation-Axis Origin and Rotation-Axis Direction for the fluid zone. See above for details.

**Important**

You can fix values for species mass fractions only if you are using the pressure-based solver.

### 6.2.4.2.4. Fixing Turbulence Quantities

To fix the values of \( k \) and \( \varepsilon \) in the \( k-\varepsilon \) equations, specify the Turbulence Kinetic Energy and Turbulence Dissipation Rate values. The units for \( k \) are \( m^2/s^2 \) and those for \( \varepsilon \) are \( m^2/s^3 \).

To fix the value of the modified turbulent viscosity (\( \bar{v} \)) for the Spalart-Allmaras model, specify the Modified Turbulent Viscosity value. The units for the modified turbulent viscosity are \( m^2/s \).

To fix the values of \( k \) and \( \omega \) in the \( k-\omega \) equations, specify the Turbulence Kinetic Energy and Specific Dissipation Rate values. The units for \( k \) are \( m^2/s^2 \) and those for \( \omega \) are \( 1/s \).

To fix the value of \( k, \varepsilon, \) or the Reynolds stresses in the RSM transport equations, specify the Turbulence Kinetic Energy, Turbulence Dissipation Rate, UU Reynolds Stress, VV Reynolds Stress, WW Reynolds Stress, UV Reynolds Stress, VW Reynolds Stress, and/or UW Reynolds Stress. The units for \( k \) and the Reynolds stresses are \( m^2/s^2 \), and those for \( \varepsilon \) are \( m^2/s^3 \).

If you specify a radial-type profile (see Profile Specification Types (p. 377)) for \( k, \varepsilon, \omega, \) or \( \bar{v} \); the local coordinate system upon which the radial profile is based is defined by the Rotation-Axis Origin and Rotation-Axis Direction for the fluid zone. See above for details. Note that you cannot specify radial-type profiles for the Reynolds stresses.

### 6.2.4.2.5. Fixing User-Defined Scalars

To fix the value of a user-defined scalar, specify the User-defined scalar value. (There will be one for each user-defined scalar you have defined.) The units for a user-defined scalar will be the appropriate SI units for the scalar quantity. See the UDF Manual for information on user-defined scalars.
6.2.5. Locking the Temperature for Solid and Shell Zones

You can lock (or “freeze”) the temperature values for all the cells in solid zones (including those to which you have hooked an energy source through a UDF) and in walls that have shell conduction enabled, so that the values do not change during further solver iterations. When the temperature is locked for a given cell, the transport equation will still be solved in the cell, and the cell will be included when the residual sum is computed.

You can lock / unlock the temperature for solid and shell zones by using the following text command:

\[ \text{solve} \rightarrow \text{set} \rightarrow \text{lock-solid-temperature?} \]

Note the following about the option for locking the temperature of solid and shell zones:

- It is only available when energy is enabled and the pressure-based solver is selected.

- When this option is used, the BCGSTAB option from the Stabilization Method drop-down list of the Advanced Solution Controls dialog box is not supported.

- Alternative means of monitoring the convergence of energy may be used.

6.2.6. Defining Mass, Momentum, Energy, and Other Sources

You can define volumetric sources of mass (for single or multiple species), momentum, energy, turbulence, and other scalar quantities in a fluid zone, or a source of energy for a solid zone. This feature is useful when you want to input a known value for these sources. (For more complicated sources with functional dependency, you can create a user-defined function as described in the separate UDF Manual.) To add source terms to a cell or group of cells, you must place the cell(s) in a separate zone. The sources are then applied to that cell zone. Typical uses for this feature are listed below:

- A flow source that cannot be represented by an inlet, for example, due to an issue of scale. If you need to model an inlet that is smaller than a cell, you can place the cell where the tiny “inlet” is located in its own fluid zone and then define the mass, momentum, and energy sources in that cell zone. For the example shown in Figure 6.16: Defining a Source for a Tiny Inlet (p. 252), you should set a mass source of

\[ \frac{\bar{m}}{\bar{V}} = \frac{\rho_{f} A_{j} v_{j}}{V} \]

and a momentum source of

\[ \frac{\bar{m} \vec{v}}{\bar{V}} = \frac{\bar{m} \vec{v}_{j}}{V} \],

where \( V \) is the cell volume.

- Heat release due to a source (for example, fire) that is not explicitly defined in your model. For this case, you can place the cell(s) into which the heat is originally released in its own fluid zone and then define the energy source in that cell zone.

- An energy source in a solid zone, for conjugate heat transfer applications. For this case, you can place the cell(s) into which the heat is originally released in its own solid zone and then define the energy source in that cell zone.

- A species source due to a reaction that is not explicitly included in the model. In the above example of simulating a fire, you might need to define a source for a species representing smoke generation.

**Important**

Note that if you define a mass source for a cell zone, you should also define a momentum source and, if appropriate for your model, energy and turbulence sources. If you define only
a mass source, that mass enters the domain with no momentum or thermal heat. The mass will therefore have to be accelerated and heated by the flow and, consequently, there may be a drop in velocity or temperature. This drop may or may not be perceptible, depending on the size of the source. (Note that defining only a momentum, energy, or turbulence source is acceptable.)

**Figure 6.16: Defining a Source for a Tiny Inlet**

6.2.6.1. **Sign Conventions and Units**

All positive source terms indicate sources, and all negative source terms indicate sinks. All sources must be specified in SI units.

6.2.6.2. **Procedure for Defining Sources**

To define one or more source terms for a zone, follow these steps (remembering to use only SI units):

1. In the Fluid Dialog Box (p. 2085) or Solid Dialog Box (p. 2092), turn on the **Source Terms** option.

2. Set the appropriate source terms under the **Source Terms** tab, noting the comments below.

   - To specify a source, click the **Edit...** button next to the mass, momentum, energy, or other source. The sources dialog box will open where you will define the number of sources. For each source, choose **none, constant**, or **New Input Parameter...** in the drop-down list.

   - If you do not want to specify a source term for a variable, choose (or keep) **none** in the drop-down list next to the relevant field. This is the default for all variables.

   - To specify a constant source, choose **constant** in the drop-down list and then enter the constant value in the field.

   - To specify a new source parameter, choose **New Input Parameter...** in the drop-down list and enter the **Name** or the parameter and the **Current Value** as a constant.
• Remember that you should not define just a mass source without defining the other sources, as described in Defining Mass, Momentum, Energy, and Other Sources (p. 251). above.

• Since the sources you specify are defined per unit volume, to determine the appropriate value of your source term you will often need to first determine the volume of the cell(s) in the zone for which you are defining the source. To do this, you can use the Volume Integrals Dialog Box (p. 2359).

6.2.6.2.1. Mass Sources

If you have only one species in your problem, you can simply define a Mass source for that species. The units for the mass source are \( \text{kg} / \text{m}^3 \). In the continuity equation (Equation 1.1 in the Theory Guide), the defined mass source will appear in the \( S_m \) term.

If you have more than one species, you can specify mass sources for each individual species. There will be a total Mass source term as well as a source term listed explicitly for each species (for example, \( h_2 \), \( o_2 \)) except the last one you defined. If the total of all species mass sources (including the last one) is 0, then you should specify a value of 0 for the Mass source, and also specify the values of the non-zero individual species mass sources. Since you cannot specify the mass source for the last species explicitly, ANSYS Fluent will compute it by subtracting the sum of all other species mass sources from the specified total Mass source.

For example, if the mass source for hydrogen in a hydrogen-air mixture is 0.01, the mass source for oxygen is 0.02, and the mass source for nitrogen (the last species) is 0.015, you will specify a value of 0.01 in the \( h_2 \) field, a value of 0.02 in the \( o_2 \) field, and a value of 0.045 in the Mass field. This concept also applies within each cell if you use user-defined functions for species mass sources.

The units for the species mass sources are \( \text{kg} / \text{m}^3 \). In the conservation equation for a chemical species (Equation 7.1 in the Theory Guide), the defined mass source will appear in the \( S_i \) term.

6.2.6.2.2. Momentum Sources

To define a source of momentum, specify the \( X \) Momentum, \( Y \) Momentum, and/or \( Z \) Momentum term. The units for the momentum source are \( \text{N/m}^3 \). In the momentum equation (Equation 1.3 in the Theory Guide), the defined momentum source will appear in the \( \ddot{F} \) term.

6.2.6.2.3. Energy Sources

To define a source of energy, specify an Energy term. The units for the energy source are \( \text{W/m}^3 \). In the energy equation (Equation 5.1 in the Theory Guide), the defined energy source will appear in the \( S_{hi} \) term.

6.2.6.2.4. Turbulence Sources

6.2.6.2.4.1. Turbulence Sources for the \( k-\varepsilon \) Model

To define a source of \( k \) or \( \varepsilon \) in the \( k-\varepsilon \) equations, specify the Turbulent Kinetic Energy or Turbulent Dissipation Rate term. The units for the \( k \) source are \( \text{kg/m} \cdot \text{s}^3 \) and those for \( \varepsilon \) are \( \text{kg/m} \cdot \text{s}^4 \).

The defined \( k \) source will appear in the \( S_k \) term on the right-hand side of the turbulent kinetic energy equation (for example, Equation 4.33 in the Theory Guide).
The defined $\epsilon$ source will appear in the $S_\epsilon$ term on the right-hand side of the turbulent dissipation rate equation (for example, Equation 4.34 in the Theory Guide).

### 6.2.6.2.4.2. Turbulence Sources for the Spalart-Allmaras Model

To define a source of modified turbulent viscosity, specify the **Modified Turbulent Viscosity** term. The units for the modified turbulent viscosity source are $\text{kg/m}^2 \cdot \text{s}^2$. In the transport equation for the Spalart-Allmaras model (Equation 4.15 in the Theory Guide), the defined modified turbulent viscosity source will appear in the $S_\nu$ term.

### 6.2.6.2.4.3. Turbulence Sources for the $k$- $\omega$ Model

To define a source of $k$ or $\omega$ in the $k$- $\omega$ equations, specify the **Turbulent Kinetic Energy** or **Specific Dissipation Rate** term. The units for the $k$ source are $\text{kg/m}^3 \cdot \text{s}$ and those for $\omega$ are $\text{kg/m}^3 \cdot \text{s}^2$.

The defined $k$ source will appear in the $S_k$ term on the right-hand side of the turbulent kinetic energy equation (Equation 4.64 in the Theory Guide).

The defined $\omega$ source will appear in the $S_\omega$ term on the right-hand side of the specific turbulent dissipation rate equation (Equation 4.65 in the Theory Guide).

### 6.2.6.2.4.4. Turbulence Sources for the Reynolds Stress Model

To define a source of $k$, $\epsilon$, or the Reynolds stresses in the RSM transport equations, specify the **Turbulence Kinetic Energy**, **Turbulence Dissipation Rate**, **UU Reynolds Stress**, **VV Reynolds Stress**, **WW Reynolds Stress**, **UV Reynolds Stress**, **VW Reynolds Stress**, and/or **UW Reynolds Stress** terms. The units for the $k$ source and the sources of Reynolds stress are $\text{kg/m}^3 \cdot \text{s}$, and those for $\epsilon$ are $\text{kg/m}^4 \cdot \text{s}^3$.

The defined Reynolds stress sources will appear in the $S_{\text{user}}$ term on the right-hand side of the Reynolds stress transport equation (Equation 4.192 in the Theory Guide).

The defined $k$ source will appear in the $S_k$ term on the right-hand side of Equation 4.219 in the Theory Guide.

The defined $\epsilon$ will appear in the $S_\epsilon$ term on the right-hand side of Equation 4.222 in the Theory Guide.

### 6.2.6.2.5. Mean Mixture Fraction and Variance Sources

To define a source of the mean mixture fraction or its variance for the non-premixed combustion model, specify the **Mean Mixture Fraction** or **Mixture Fraction Variance** term. The units for the mean mixture fraction source are $\text{kg} / \text{m}^3$ and those for the mixture fraction variance source are $\text{kg} / \text{m}^2$.

The defined mean mixture fraction source will appear in the $S_{\text{user}}$ term in the transport equation for the mixture fraction (Equation 8.4 in the Theory Guide).

The defined mixture fraction variance source will appear in the $S_{\text{user}}$ term in the transport equation for the mixture fraction variance (Equation 8.5 in the Theory Guide).

If you are using the two-mixture-fraction approach, you can also specify sources of the **Secondary Mean Mixture Fraction** and **Secondary Mixture Fraction Variance**.
6.2.6.2.6. P-1 Radiation Sources

To define a source for the P-1 radiation model, specify the \( P1 \) term. The units for the radiation source are \( \text{W/m}^3 \), and the defined source will appear in the \( S_G \) term in Equation 5.18 in the Theory Guide.

Note that, if the source term you are defining represents a transfer from internal energy to radiative energy (for example, absorption or emission), you must specify an Energy source of the same magnitude as the \( P1 \) source, but with the opposite sign, in order to ensure overall energy conservation.

6.2.6.2.7. Progress Variable Sources

To define a source of the progress variable for the premixed combustion model, specify the Progress Variable term. The units for the progress variable source are \( \text{kg/m}^3 \cdot \text{s} \), and the defined source will appear in the \( \rho S_c \) term in Equation 9.1 in the Theory Guide.

6.2.6.2.8. NO, HCN, and NH3 Sources for the NOx Model

To define a source of NO, HCN, or \( \text{NH}_3 \) for the NOx model, specify the \( \text{no} \), \( \text{hcn} \), or \( \text{nh3} \) term. The units for these sources are \( \text{kg/m}^3 \cdot \text{s} \), and the defined sources will appear in the \( S_{NO} \), \( S_{HCN} \), and \( S_{NH3} \) terms of Equation 14.1, Equation 14.2, and Equation 14.3 in the Theory Guide.

6.2.6.2.9. User-Defined Scalar (UDS) Sources

You can specify source term(s) for each UDS transport equation you have defined in your model. See Setting Up UDS Equations in ANSYS Fluent (p. 507) for details.

6.3. Boundary Conditions

Boundary conditions consist of flow inlets and exit boundaries, wall, repeating, and pole boundaries, and internal face boundaries. All the various types of boundary conditions are discussed in the sections that follow.

6.3.1. Flow Inlet and Exit Boundary Conditions
6.3.2. Using Flow Boundary Conditions
6.3.3. Pressure Inlet Boundary Conditions
6.3.4. Velocity Inlet Boundary Conditions
6.3.5. Mass Flow Inlet Boundary Conditions
6.3.6. Inlet Vent Boundary Conditions
6.3.7. Intake Fan Boundary Conditions
6.3.8. Pressure Outlet Boundary Conditions
6.3.9. Pressure Far-Field Boundary Conditions
6.3.10. Outflow Boundary Conditions
6.3.11. Outlet Vent Boundary Conditions
6.3.12. Exhaust Fan Boundary Conditions
6.3.13. Degassing Boundary Conditions
6.3.14. Wall Boundary Conditions
6.3.15. Symmetry Boundary Conditions
6.3.16. Periodic Boundary Conditions
6.3.17. Axis Boundary Conditions
6.3.18. Fan Boundary Conditions
6.3.19. Radiator Boundary Conditions
6.3.20. Porous Jump Boundary Conditions
6.3.1. Flow Inlet and Exit Boundary Conditions

ANSYS Fluent has a wide range of boundary conditions that permit flow to enter and exit the solution domain. To help you select the most appropriate boundary condition for your application, this section includes descriptions of how each type of condition is used, and what information is needed for each one. Recommendations for determining inlet values of the turbulence parameters are also provided.

6.3.2. Using Flow Boundary Conditions

This section provides an overview of flow boundaries in ANSYS Fluent and how to use them.

ANSYS Fluent provides 10 types of boundary zone types for the specification of flow inlets and exits: velocity inlet, pressure inlet, mass flow inlet, pressure outlet, pressure far-field, outflow, inlet vent, intake fan, outlet vent, and exhaust fan.

The inlet and exit boundary condition options in ANSYS Fluent are as follows:

• Velocity inlet boundary conditions are used to define the velocity and scalar properties of the flow at inlet boundaries.

• Pressure inlet boundary conditions are used to define the total pressure and other scalar quantities at flow inlets.

• Mass flow inlet boundary conditions are used in compressible flows to prescribe a mass flow rate at an inlet. It is not necessary to use mass flow inlets in incompressible flows because when density is constant, velocity inlet boundary conditions will fix the mass flow. Like pressure and velocity inlets, other inlet scalars are also prescribed.

• Pressure outlet boundary conditions are used to define the static pressure at flow outlets (and also other scalar variables, in case of backflow). The use of a pressure outlet boundary condition instead of an outflow condition often results in a better rate of convergence when backflow occurs during iteration.

• Pressure far-field boundary conditions are used to model a free-stream compressible flow at infinity, with free-stream Mach number and static conditions specified. This boundary type is available only for compressible flows.

• Outflow boundary conditions are used to model flow exits where the details of the flow velocity and pressure are not known prior to solution of the flow problem. They are appropriate where the exit flow is close to a fully developed condition, as the outflow boundary condition assumes a zero streamwise gradient for all flow variables except pressure. They are not appropriate for compressible flow calculations.

• Inlet vent boundary conditions are used to model an inlet vent with a specified loss coefficient, flow direction, and ambient (inlet) total pressure and temperature.

• Intake fan boundary conditions are used to model an external intake fan with a specified pressure jump, flow direction, and ambient (intake) total pressure and temperature.

• Outlet vent boundary conditions are used to model an outlet vent with a specified loss coefficient and ambient (discharge) static pressure and temperature.

• Exhaust fan boundary conditions are used to model an external exhaust fan with a specified pressure jump and ambient (discharge) static pressure.
• Degassing boundary conditions are used to model a free surface through which dispersed gas bubbles are allowed to escape, but the continuous liquid phase is not. A typical application is a bubble column in which you want to reduce computational cost by not including the freeboard region in the simulation. The degassing boundary condition is only available for two-phase liquid-gas flows using the Eulerian multiphase model.

6.3.2.1. Determining Turbulence Parameters

When the flow enters the domain at an inlet, outlet, or far-field boundary, ANSYS Fluent requires specification of transported turbulence quantities. This section describes which quantities are needed for specific turbulence models and how they must be specified. It also provides guidelines for the most appropriate way of determining the inflow boundary values.

6.3.2.1.1. Specification of Turbulence Quantities Using Profiles

If it is important to accurately represent a boundary layer or fully-developed turbulent flow at the inlet, you should ideally set the turbulence quantities by creating a profile file (see Profiles (p. 377)) from experimental data or empirical formulas. If you have an analytical description of the profile, rather than data points, you can either use this analytical description to create a profile file, or create a user-defined function to provide the inlet boundary information. (See the UDF Manual for information on user-defined functions.)

Once you have created the profile function, you can use it as described below:

• Spalart-Allmaras model: Choose Turbulent Viscosity or Turbulent Viscosity Ratio in the Turbulence Specification Method drop-down list and select the appropriate profile name in the drop-down list next to Turbulent Viscosity or Turbulent Viscosity Ratio. ANSYS Fluent computes the boundary value for the modified turbulent viscosity, \( \bar{\nu} \), by combining \( \frac{\mu}{\mu_t} \) with the appropriate values of density and molecular viscosity.

• \( k-\epsilon \) models: Choose K and Epsilon in the Turbulence Specification Method drop-down list and select the appropriate profile names in the drop-down lists next to Turbulent Kinetic Energy and Turbulent Dissipation Rate.

• \( k-\omega \) models: Choose K and Omega in the Turbulence Specification Method drop-down list and select the appropriate profile names in the drop-down lists next to Turbulent Kinetic Energy and Specific Dissipation Rate.

• Reynolds stress model: Choose K and Epsilon in the Turbulence Specification Method drop-down list and select the appropriate profile names in the drop-down lists next to Turbulent Kinetic Energy and Turbulent Dissipation Rate. Choose Reynolds-Stress Components in the Reynolds-Stress Specification Method drop-down list and select the appropriate profile name in the drop-down list next to each of the individual Reynolds-stress components.

6.3.2.1.2. Uniform Specification of Turbulence Quantities

In some situations, it is appropriate to specify a uniform value of the turbulence quantity at the boundary where inflow occurs. Examples are fluid entering a duct, far-field boundaries, or even fully-developed duct flows where accurate profiles of turbulence quantities are unknown.

In most turbulent flows, higher levels of turbulence are generated within shear layers than enter the domain at flow boundaries, making the result of the calculation relatively insensitive to the inflow
boundary values. Nevertheless, caution must be used to ensure that boundary values are not so unphysical as to contaminate your solution or impede convergence. This is particularly true of external flows where unphysically large values of effective viscosity in the free stream can “swamp” the boundary layers.

You can use the turbulence specification methods described above to enter uniform constant values instead of profiles. Alternatively, you can specify the turbulence quantities in terms of more convenient quantities such as turbulence intensity, turbulent viscosity ratio, hydraulic diameter, and turbulence length scale. The default Turbulence Specification Method is set to Turbulent Viscosity Ratio (for the Spalart-Allmaras model) or Intensity and Viscosity Ratio (for the k-ε models, the k-ω models, or the RSM). These quantities are discussed further in the following sections.

6.3.2.1.3. Turbulence Intensity

The turbulence intensity, $I$, is defined as the ratio of the root-mean-square of the velocity fluctuations, $u'$, to the mean flow velocity, $u_{avg}$.

A turbulence intensity of 1% or less is generally considered low and turbulence intensities greater than 10% are considered high. Ideally, you will have a good estimate of the turbulence intensity at the inlet boundary from external, measured data. For example, if you are simulating a wind-tunnel experiment, the turbulence intensity in the free stream is usually available from the tunnel characteristics. In modern low-turbulence wind tunnels, the free-stream turbulence intensity may be as low as 0.05%.

For internal flows, the turbulence intensity at the inlets is totally dependent on the upstream history of the flow. If the flow upstream is under-developed and undisturbed, you can use a low turbulence intensity. If the flow is fully developed, the turbulence intensity may be as high as a few percent. The turbulence intensity at the core of a fully-developed duct flow can be estimated from the following formula derived from an empirical correlation for pipe flows:

$$ I \equiv \frac{u'}{u_{avg}} = 0.16 \left( \frac{Re_{D_H}}{D_H} \right)^{-1/8} $$

At a Reynolds number of 50,000, for example, the turbulence intensity will be 4%, according to this formula.

The default value for turbulence intensity is 5% (medium intensity).

6.3.2.1.4. Turbulence Length Scale and Hydraulic Diameter

The turbulence length scale, $\ell$, is a physical quantity related to the size of the large eddies that contain the energy in turbulent flows.

In fully-developed duct flows, $\ell$ is restricted by the size of the duct, since the turbulent eddies cannot be larger than the duct. An approximate relationship between $\ell$ and the physical size of the duct is

$$ \ell = 0.07L $$

where $L$ is the relevant dimension of the duct. The factor of 0.07 is based on the maximum value of the mixing length in fully-developed turbulent pipe flow, where $L$ is the diameter of the pipe. In a channel of non-circular cross-section, you can base $L$ on the hydraulic diameter.

If the turbulence derives its characteristic length from an obstacle in the flow, such as a perforated plate, it is more appropriate to base the turbulence length scale on the characteristic length of the obstacle rather than on the duct size.
It should be noted that the relationship of Equation 6.44 (p. 258), which relates a physical dimension ($L$) to the turbulence length scale ($\ell$), is not necessarily applicable to all situations. For most cases, however, it is a suitable approximation.

Guidelines for choosing the characteristic length $L$ or the turbulence length scale $\ell$ for selected flow types are listed below:

- For fully-developed internal flows, choose the **Intensity and Hydraulic Diameter** specification method and specify the hydraulic diameter $L = D_H$ in the **Hydraulic Diameter** field.

- For flows downstream of turning vanes, perforated plates, etc., choose the **Intensity and Length Scale** method and specify the characteristic length of the flow opening for $L$ in the **Turbulent Length Scale** field.

- For wall-bounded flows in which the inlets involve a turbulent boundary layer, choose the **Intensity and Length Scale** method and use the boundary-layer thickness, $\delta_{99}$, to compute the turbulence length scale, $\ell$, from $\ell = 0.4\delta_{99}$. Enter this value for $\ell$ in the **Turbulence Length Scale** field.

**6.3.2.1.5. Turbulent Viscosity Ratio**

The turbulent viscosity ratio, $\frac{\mu_t}{\mu}$, is directly proportional to the turbulent Reynolds number $\text{Re}_t \equiv k^2 / (\epsilon \nu)$. $\text{Re}_t$ is large (on the order of 100 to 1000) in high-Reynolds-number boundary layers, shear layers, and fully-developed duct flows. However, at the free-stream boundaries of most external flows, $\frac{\mu_t}{\mu}$ is fairly small. Typically, the turbulence parameters are set so that $1 < \frac{\mu_t}{\mu} < 10$. For internal flows values up to 100 are sensible for the turbulent viscosity ratio, $\frac{\mu_t}{\mu}$. The default value for the turbulent viscosity ratio is set to 10.

To specify quantities in terms of the turbulent viscosity ratio, you can choose **Turbulent Viscosity Ratio** (for the Spalart-Allmaras model) or **Intensity and Viscosity Ratio** (for the $k-\epsilon$ models, the $k-\omega$ models, or the RSM). The default value for the turbulence intensity is set to 5% (medium intensity) and the turbulent viscosity ratio, $\frac{\mu_t}{\mu}$, has a default value of 10.

**6.3.2.1.6. Relationships for Deriving Turbulence Quantities**

To obtain the values of transported turbulence quantities from more convenient quantities such as $I$, $L$, or $\frac{\mu_t}{\mu}$, you must typically resort to an empirical relation. Several useful relations, most of which are used within ANSYS Fluent, are presented below.

**6.3.2.1.7. Estimating Modified Turbulent Viscosity from Turbulence Intensity and Length Scale**

To obtain the modified turbulent viscosity, $\tilde{v}$, for the Spalart-Allmaras model from the turbulence intensity, $I$, and length scale, $\ell$, the following equation can be used:

$$\tilde{v} = \sqrt{\frac{3}{2}} u_{avg} I \ell$$

(6.45)
This formula is used in ANSYS Fluent if you select the **Intensity and Hydraulic Diameter** specification method with the Spalart-Allmaras model. \( \ell \) is obtained from Equation 6.44 (p. 258).

### 6.3.2.1.8. Estimating Turbulent Kinetic Energy from Turbulence Intensity

The relationship between the turbulent kinetic energy, \( k \), and turbulence intensity, \( I \), is

\[
k = \frac{3}{2} \left( u_{avg} \ell \right)^2
\]

where \( u_{avg} \) is the mean flow velocity.

This relationship is used in ANSYS Fluent whenever the **Intensity and Hydraulic Diameter**, **Intensity and Length Scale**, or **Intensity and Viscosity Ratio** method is used instead of specifying explicit values for \( k \) and \( \varepsilon \).

### 6.3.2.1.9. Estimating Turbulent Dissipation Rate from a Length Scale

If you know the turbulence length scale, \( \ell \), you can determine \( \varepsilon \) from the relationship

\[
\varepsilon = C_\mu^{3/4} k^{3/2} \ell
\]

where \( C_\mu \) is an empirical constant specified in the turbulence model (approximately 0.09). The determination of \( \ell \) was discussed previously.

This relationship is used in ANSYS Fluent whenever the **Intensity and Hydraulic Diameter** or **Intensity and Length Scale** method is used instead of specifying explicit values for \( k \) and \( \varepsilon \).

### 6.3.2.1.10. Estimating Turbulent Dissipation Rate from Turbulent Viscosity Ratio

The value of \( \varepsilon \) can be obtained from the turbulent viscosity ratio \( \frac{\mu_t}{\mu} \) and \( k \) using the following relationship:

\[
\varepsilon = \frac{\rho C_\mu k^2}{\mu} \left( \frac{\mu_t}{\mu} \right)^{-1}
\]

where \( C_\mu \) is an empirical constant specified in the turbulence model (approximately 0.09).

This relationship is used in ANSYS Fluent whenever the **Intensity and Viscosity Ratio** method is used instead of specifying explicit values for \( k \) and \( \varepsilon \).

### 6.3.2.1.11. Estimating Turbulent Dissipation Rate for Decaying Turbulence

If you are simulating a wind-tunnel situation in which the model is mounted in the test section downstream of a mesh and/or wire mesh screens, you can choose a value of \( \varepsilon \) such that

\[
\varepsilon \approx \frac{\Delta k U_\infty}{L_\infty}
\]

where \( \Delta k \) is the approximate decay of \( k \) you want to have across the flow domain (say, 10% of the inlet value of \( k \)), \( U_\infty \) is the free-stream velocity, and \( L_\infty \) is the streamwise length of the flow domain.
Equation 6.49 (p. 260) is a linear approximation to the power-law decay observed in high-Reynolds-number isotropic turbulence. Its basis is the exact equation for $k$ in decaying turbulence, $U \frac{\partial k}{\partial x} = -\varepsilon$.

If you use this method to estimate $\varepsilon$, you should also check the resulting turbulent viscosity ratio $\frac{\mu_t}{\mu}$ to make sure that it is not too large, using Equation 6.48 (p. 260).

Although this method is not used internally by ANSYS Fluent, you can use it to derive a constant free-stream value of $\varepsilon$ that you can then specify directly by choosing K and Epsilon in the Turbulence Specification Method drop-down list. In this situation, you will typically determine $k$ from $I$ using Equation 6.46 (p. 260).

### 6.3.2.1.12. Estimating Specific Dissipation Rate from a Length Scale

If you know the turbulence length scale, $\ell$, you can determine $\omega$ from the relationship

$$\omega = \frac{k^{1/2}}{C_{\mu}^{1/4} \ell}$$  \hspace{1cm} (6.50)

where $C_{\mu}$ is an empirical constant specified in the turbulence model (approximately 0.09). The determination of $\ell$ was discussed previously.

This relationship is used in ANSYS Fluent whenever the Intensity and Hydraulic Diameter or Intensity and Length Scale method is used instead of specifying explicit values for $k$ and $\omega$.

### 6.3.2.1.13. Estimating Specific Dissipation Rate from Turbulent Viscosity Ratio

The value of $\omega$ can be obtained from the turbulent viscosity ratio $\frac{\mu_t}{\mu}$ and $k$ using the following relationship:

$$\omega = \rho \frac{k}{\mu} \left( \frac{\mu_t}{\mu} \right)^{-1}$$  \hspace{1cm} (6.51)

This relationship is used in ANSYS Fluent whenever the Intensity and Viscosity Ratio method is used instead of specifying explicit values for $k$ and $\omega$.

### 6.3.2.1.14. Estimating Reynolds Stress Components from Turbulent Kinetic Energy

When the RSM is used, if you do not specify the values of the Reynolds stresses explicitly at the inlet using the Reynolds-Stress Components option in the Reynolds-Stress Specification Method drop-down list, they are approximately determined from the specified values of $k$. The turbulence is assumed to be isotropic such that

$$\overline{u_i u_j} = 0$$  \hspace{1cm} (6.52)

and

$$\overline{u_i \mu_{\alpha \alpha}} = \frac{2}{3} k$$  \hspace{1cm} (6.53)

(no summation over the index $\alpha$).
ANSYS Fluent will use this method if you select K or Turbulence Intensity in the Reynolds-Stress Specification Method drop-down list.

### 6.3.2.1.15. Specifying Inlet Turbulence for LES

The turbulence intensity value specified at a velocity inlet for LES, as described in Large Eddy Simulation Model (p. 743), is used to randomly perturb the instantaneous velocity field at the inlet. It does not specify a modeled turbulence quantity. Instead, the stochastic components of the flow at the inlet boundary are accounted for by superposing random perturbations on individual velocity components as described in Inlet Boundary Conditions for the LES Model in the Theory Guide.

### 6.3.3. Pressure Inlet Boundary Conditions

Pressure inlet boundary conditions are used to define the fluid pressure at flow inlets, along with all other scalar properties of the flow. They are suitable for both incompressible and compressible flow calculations. Pressure inlet boundary conditions can be used when the inlet pressure is known but the flow rate and/or velocity is not known. This situation may arise in many practical situations, including buoyancy-driven flows. Pressure inlet boundary conditions can also be used to define a “free” boundary in an external or unconfined flow.

For an overview of flow boundaries, see Flow Inlet and Exit Boundary Conditions (p. 256).

### 6.3.3.1. Inputs at Pressure Inlet Boundaries

#### 6.3.3.1.1. Summary

You will enter the following information for a pressure inlet boundary:

- type of reference frame
- total (stagnation) pressure
- total (stagnation) temperature
- flow direction
- static pressure
- turbulence parameters (for turbulent calculations)
- radiation parameters (for calculations using the P-1 model, the DTRM, the DO model, or the surface-to-surface model)
- chemical species mass or mole fractions (for species calculations)
- mixture fraction and variance (for non-premixed or partially premixed combustion calculations)
- progress variable (for premixed or partially premixed combustion calculations)
- discrete phase boundary conditions (for discrete phase calculations)
- multiphase boundary conditions (for general multiphase calculations)
- open channel flow parameters (for open channel flow calculations using the VOF multiphase model)
All values are entered in the Pressure Inlet Dialog Box (p. 2142) (Figure 6.17: The Pressure Inlet Dialog Box (p. 263)), which is opened from the Boundary Conditions task page (as described in Setting Cell Zone and Boundary Conditions (p. 204)). Note that open channel boundary condition inputs are described in Modeling Open Channel Flows (p. 1275).

Figure 6.17: The Pressure Inlet Dialog Box

![Pressure Inlet Dialog Box](image)

6.3.3.1.1.1. Pressure Inputs and Hydrostatic Head

When gravitational acceleration is activated in the Operating Conditions dialog box (accessed from the Boundary Conditions task page), the pressure field (including all pressure inputs) will include the hydrostatic head. This is accomplished by redefining the pressure in terms of a modified pressure which includes the hydrostatic head (denoted \( p' \)) as follows:

\[
p' = p - \rho_0 \vec{g} \cdot \vec{r}
\]  \hspace{1cm} (6.54)

where \( \rho_0 \) is a constant reference density, \( \vec{g} \) is the gravity vector (also a constant), and

\[
\vec{r} = x\hat{i} + y\hat{j} + z\hat{k}
\]  \hspace{1cm} (6.55)

is the position vector. Noting that

\[
\nabla (\rho_0 \vec{g} \cdot \vec{r}) = \rho_0 \vec{g}
\]  \hspace{1cm} (6.56)
it follows that
\[ \nabla p' = \nabla \left( p - \rho_0 \bar{g} \cdot \vec{r} \right) = \nabla p - \rho_0 \bar{g} \]  \hspace{1cm} (6.57)

The substitution of this relation in the momentum equation gives pressure gradient and gravitational body force terms of the form
\[ -\nabla p' + (\rho - \rho_0) \bar{g} \]  \hspace{1cm} (6.58)

where \( \rho \) is the fluid density. Therefore, if the fluid density is constant, we can set the reference density \( \rho_0 \) equal to the fluid density, thereby eliminating the body force term. If the fluid density is not constant (for example, density is given by the ideal gas law), then the reference density should be chosen to be representative of the average or mean density in the fluid domain, so that the body force term is small.

An important consequence of this treatment of the gravitational body force is that your inputs of pressure (now defined as \( p' \)) should not include hydrostatic pressure differences. Moreover, reports of static and total pressure will not show any influence of the hydrostatic pressure. See Natural Convection and Buoyancy-Driven Flows (p. 765) for additional information.

### 6.3.3.1.1.2. Defining Total Pressure and Temperature

Enter the value for total pressure in the **Gauge Total Pressure** field in the **Pressure Inlet** dialog box. Total temperature is set in the **Thermal** tab, in the **Total Temperature** field.

Remember that the total pressure value is the gauge pressure with respect to the operating pressure defined in the Operating Conditions Dialog Box (p. 2095). Total pressure for an incompressible fluid is defined as
\[ p_0 = p_s + \frac{1}{2} \rho \| \vec{V} \|^2 \]  \hspace{1cm} (6.59)

and for a compressible fluid of constant \( c_p \) as
\[ p_0 = p_s \left( 1 + \frac{\gamma - 1}{2} M^2 \right)^{\gamma/(\gamma - 1)} \]  \hspace{1cm} (6.60)

where
- \( p_0 \) = total pressure
- \( p_s \) = static pressure
- \( M \) = Mach number
- \( \gamma \) = ratio of specific heats \( \left( c_p/c_v \right) \)

If you are modeling axisymmetric swirl, \( \vec{V} \) in Equation 6.59 (p. 264) will include the swirl component.

If the cell zone adjacent to a pressure inlet is defined as a moving reference frame zone, and you are using the pressure-based solver, the velocity in Equation 6.59 (p. 264) (or the Mach number in Equation 6.60 (p. 264)) will be absolute or relative to the mesh velocity, depending on whether or not the Absolute velocity formulation is enabled in the General task page. For the density-based solver, the Absolute velocity formulation is always used; hence, the velocity in Equation 6.59 (p. 264) (or the Mach number in Equation 6.60 (p. 264)) is always the Absolute velocity.
• If Reference Frame is set to Absolute in the Pressure Inlet dialog box, then the total temperature, total pressure, and flow direction are also in the absolute reference frame, and therefore, the ANSYS Fluent solver will convert it to the relative reference frame.

• If Reference Frame is set to Relative to Adjacent Cell Zone in the Pressure Inlet dialog box, then the total temperature, total pressure, and velocity components are also relative to the adjacent cell zone and no change is needed.

For the Eulerian multiphase model, the total temperature, and velocity components must be specified for the individual phases. The Reference Frame (Relative to Adjacent Cell Zone or Absolute) for each of the phases is the same as the reference frame selected for the mixture phase. Note that the total pressure values must be specified in the mixture phase.

**Important**

• If the flow is incompressible, then the temperature assigned in the Pressure Inlet dialog box will be considered the static temperature.

• For the mixture multiphase model, if a boundary allows a combination of compressible and incompressible phases to enter the domain, then the temperature assigned in the Pressure Inlet dialog box will be considered the static temperature at that boundary. If a boundary allows only a compressible phase to enter the domain, then the temperature assigned in the Pressure Inlet dialog box will be taken as the total temperature (relative/absolute) at that boundary. The total temperature will depend on the Reference Frame option selected in the Pressure Inlet dialog box.

• For the VOF multiphase model, if a boundary allows a compressible phase to enter the domain, then the temperature assigned in the Pressure Inlet dialog box will be considered the total temperature at that boundary. The total temperature (relative/absolute) will depend on the Reference Frame option chosen in the dialog box. Otherwise, the temperature assigned to the boundary will be considered the static temperature at the boundary.

• For the Eulerian multiphase model, if a boundary allows a mixture of compressible and incompressible phases in the domain, then the temperature of each of the phases will be the total or static temperature, depending on whether the phase is compressible or incompressible.

• Total temperature (relative/absolute) will depend on the Reference Frame option chosen in the Pressure Inlet dialog box.

**6.3.3.1.1.3. Defining the Flow Direction**

The flow direction is defined as a unit vector (\( \vec{d} \)) which is aligned with the local velocity vector, \( \vec{v} \). This can be expressed simply as
For the inputs in ANSYS Fluent, the flow direction \( \vec{d} \) need not be a unit vector, as it will be automatically normalized before it is applied.

For a moving reference frame, the relative flow direction \( \vec{d}_r \) is defined in terms of the relative velocity, \( \vec{V}_r \). Thus,

\[
\vec{d}_r = \frac{\vec{V}_r}{|\vec{V}_r|}
\]

You can define the flow direction at a pressure inlet explicitly, or you can define the flow to be normal to the boundary. If you choose to specify the direction vector, you can set either the (Cartesian) \( x, y, \) and \( z \) components, or the (cylindrical) radial, tangential, and axial components.

For moving zone problems calculated using the pressure-based solver, the flow direction will be absolute or relative to the mesh velocity, depending on whether or not the Absolute velocity formulation is selected in the General task page. For the density-based solver, the flow direction will always be in the absolute frame.

The procedure for defining the flow direction is as follows (refer to Figure 6.17: The Pressure Inlet Dialog Box (p. 263)):

1. Specify the flow direction by selecting Direction Vector or Normal to Boundary in the Direction Specification Method drop-down list.

2. If you selected Normal to Boundary in step 1 and you are modeling axisymmetric swirl, enter the appropriate value for the Tangential-Component of Flow Direction. If you chose Normal to Boundary and your geometry is 3D or 2D without axisymmetric swirl, there are no additional inputs for flow direction.

3. If you selected Direction Vector in step 1, and your geometry is 3D, choose Cartesian \( (X, Y, Z) \), Cylindrical \( (Radial, Tangential, Axial) \), Local Cylindrical \( (Radial, Tangential, Axial) \), or Local Cylindrical Swirl from the Coordinate System drop-down list. Some notes on these selections are provided below:

   - The Cartesian coordinate option is based on the Cartesian coordinate system used by the geometry. Enter appropriate values for the \( X, Y, \) and \( Z-Component of Flow Direction.\)

   - The Cylindrical coordinate system uses the axial, radial, and tangential components based on the following coordinate systems:

     - For problems involving a single cell zone, the coordinate system is defined by the rotation axis and origin specified in the Fluid Dialog Box (p. 2085).

     - For problems involving multiple zones (for example, multiple reference frames or sliding meshes), the coordinate system is defined by the rotation axis specified in the Fluid (or Solid) dialog box for the fluid (or solid) zone that is adjacent to the inlet.
For all of the above definitions of the cylindrical coordinate system, positive radial velocities point radially outward from the rotation axis, positive axial velocities are in the direction of the rotation axis vector, and positive tangential velocities are based on the right-hand rule using the positive rotation axis (see Figure 6.18: Cylindrical Velocity Components in 3D, 2D, and Axisymmetric Domains (p. 267)).

**Figure 6.18: Cylindrical Velocity Components in 3D, 2D, and Axisymmetric Domains**

- The **Local Cylindrical** coordinate system allows you to define a coordinate system specifically for the inlet. When you use the local cylindrical option, you will define the coordinate system right here in the Pressure Inlet dialog box. The local cylindrical coordinate system is useful if you have several inlets with different rotation axes. Enter appropriate values for the **Axial**, **Radial**, and **Tangential-Component of Flow Direction**, and then specify the **X**, **Y**, and **Z** components of the Axis Origin and Axis Direction.

- The **Local Cylindrical Swirl** coordinate system option allows you to define a coordinate system specifically for the inlet where the total pressure, swirl velocity, and the components of the velocity in the axial and radial planes are specified. Enter appropriate values for the **Axial** and **Radial-Component of Flow Direction**, and the **Tangential-Velocity**. Specify the **X**, **Y**, and **Z** components of the Axis Origin and Axis Direction. It is recommended that you start your simulation with a smaller swirl velocity and then progressively increase the velocity to obtain a stable solution.

---

**Important**

**Local Cylindrical Swirl** should not be used for open channel boundary conditions and on the mixing plane boundaries while using the mixing plane model.

---

4. If you selected **Direction Vector** in step 1, and your geometry is 2D, define the vector components as follows:

- For a 2D planar geometry, enter appropriate values for the **X**, **Y**, and **Z-Component of Flow Direction**.
- For a 2D axisymmetric geometry, enter appropriate values for the **Axial**, **Radial-Component of Flow Direction**.
• For a 2D axisymmetric swirl geometry, enter appropriate values for the Axial, Radial, and Tangential-Component of Flow Direction.

Figure 6.18: Cylindrical Velocity Components in 3D, 2D, and Axisymmetric Domains (p. 267) shows the vector components for these different coordinate systems.

6.3.3.1.1.4. Defining Static Pressure

The static pressure (termed the Supersonic/Initial Gauge Pressure) must be specified if the inlet flow is supersonic or if you plan to initialize the solution based on the pressure inlet boundary conditions. Solution initialization is discussed in Initializing the Solution (p. 1445).

Remember that the static pressure value you enter is relative to the operating pressure set in the Operating Conditions Dialog Box (p. 2095). Note the comments in Pressure Inputs and Hydrostatic Head (p. 263) regarding hydrostatic pressure.

The Supersonic/Initial Gauge Pressure is ignored by ANSYS Fluent whenever the flow is subsonic, in which case it is calculated from the specified stagnation quantities. If you choose to initialize the solution based on the pressure-inlet conditions, the Supersonic/Initial Gauge Pressure will be used in conjunction with the specified stagnation pressure to compute initial values according to the isentropic relations (for compressible flow) or Bernoulli’s equation (for incompressible flow). Therefore, for a sub-sonic inlet it should generally be set based on a reasonable estimate of the inlet Mach number (for compressible flow) or inlet velocity (for incompressible flow).

6.3.3.1.1.5. Defining Turbulence Parameters

For turbulent calculations, there are several ways in which you can define the turbulence parameters. Instructions for deciding which method to use and determining appropriate values for these inputs are provided in Determining Turbulence Parameters (p. 257). Turbulence modeling in general is described in Modeling Turbulence (p. 695).

6.3.3.1.1.6. Defining Radiation Parameters

If you are using the P-1 radiation model, the DTRM, the DO model, or the surface-to-surface model, you will set the Internal Emissivity and (optionally) External Black Body Temperature. See Defining Boundary Conditions for Radiation (p. 798) for details. (The Rosseland radiation model does not require any boundary condition inputs.)

6.3.3.1.1.7. Defining Species Mass or Mole Fractions

If you are modeling species transport, you will set the species mass or mole fractions under Species Mole Fractions or Species Mass Fractions. For details, see Defining Cell Zone and Boundary Conditions for Species (p. 910).

6.3.3.1.1.8. Defining Non-Premixed Combustion Parameters

If you are using the non-premixed or partially premixed combustion model, you will set the Mean Mixture Fraction and Mixture Fraction Variance (and the Secondary Mean Mixture Fraction and Secondary Mixture Fraction Variance, if you are using two mixture fractions), as described in Defining Non-Premixed Boundary Conditions (p. 993).
6.3.3.1.9. Defining Premixed Combustion Boundary Conditions

If you are using the premixed or partially premixed combustion model, you will set the Progress Variable, as described in Setting Boundary Conditions for the Progress Variable (p. 1008).

6.3.3.1.10. Defining Discrete Phase Boundary Conditions

If you are modeling a discrete phase of particles, you can set the fate of particle trajectories at the pressure inlet. See Setting Boundary Conditions for the Discrete Phase (p. 1189) for details.

6.3.3.1.11. Defining Multiphase Boundary Conditions

If you are using the VOF, mixture, or Eulerian model for multiphase flow, you will need to specify volume fractions for secondary phases and (for some models) additional parameters. See Defining Multiphase Cell Zone and Boundary Conditions (p. 1260) for details.

6.3.3.1.12. Defining Open Channel Boundary Conditions

If you are using the VOF model for multiphase flow and modeling open channel flows, you will need to specify the Free Surface Level, Bottom Level, and additional parameters. See Modeling Open Channel Flows (p. 1275) for details.

6.3.3.2. Default Settings at Pressure Inlet Boundaries

Default settings (in SI) for pressure inlet boundary conditions are as follows:

<table>
<thead>
<tr>
<th>Boundary Condition</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gauge Total Pressure</td>
<td>0</td>
</tr>
<tr>
<td>Supersonic/Initial Gauge Pressure</td>
<td>0</td>
</tr>
<tr>

</tr>
<tr>
<td>Direction Specification Method</td>
<td>Normal to Boundary</td>
</tr>
<tr>
<td>Turbulent Intensity</td>
<td>5%</td>
</tr>
<tr>
<td>Turbulent Viscosity Ratio</td>
<td>10</td>
</tr>
</tbody>
</table>

6.3.3.3. Calculation Procedure at Pressure Inlet Boundaries

The treatment of pressure inlet boundary conditions by ANSYS Fluent can be described as a loss-free transition from stagnation conditions to the inlet conditions. For incompressible flows, this is accomplished by application of the Bernoulli equation at the inlet boundary. In compressible flows, the equivalent isentropic flow relations for an ideal gas are used.

6.3.3.3.1. Incompressible Flow Calculations at Pressure Inlet Boundaries

When flow enters through a pressure inlet boundary, ANSYS Fluent uses the boundary condition pressure you input as the total pressure of the fluid at the inlet plane, \( p_0 \). In incompressible flow, the inlet total pressure and the static pressure, \( p_s \), are related to the inlet velocity via Bernoulli’s equation:

\[
p_0 = p_s + \frac{1}{2} \rho V^2
\]  

(6.63)
With the resulting velocity magnitude and the flow direction vector you assigned at the inlet, the velocity components can be computed. The inlet mass flow rate and fluxes of momentum, energy, and species can then be computed as outlined in *Calculation Procedure at Velocity Inlet Boundaries* (p. 276).

For incompressible flows, density at the inlet plane is either constant or calculated as a function of temperature and/or species mass/mole fractions, where the mass or mole fractions are the values you entered as an inlet condition.

If flow exits through a pressure inlet, the total pressure specified is used as the static pressure. For incompressible flows, total temperature is equal to static temperature.

### 6.3.3.3.2. Compressible Flow Calculations at Pressure Inlet Boundaries

In compressible flows, isentropic relations for an ideal gas are applied to relate total pressure, static pressure, and velocity at a pressure inlet boundary. Your input of total pressure, $p_0^\prime$, at the inlet and the static pressure, $p_s^\prime$, in the adjacent fluid cell are therefore related as

$$\frac{p_0^\prime + p_{op}}{p_s^\prime + p_{op}} = \left(1 + \frac{\gamma - 1}{2}M^2\right)^{\gamma/(\gamma - 1)} \quad (6.64)$$

where

$$M \equiv \frac{V}{c} = \frac{V}{\sqrt{\gamma RT_s}} \quad (6.65)$$

$c$ = the speed of sound, and $\gamma = c_p/c_v$. Note that the operating pressure, $p_{op}$, appears in *Equation 6.64 (p. 270)* because your boundary condition inputs are in terms of pressure relative to the operating pressure. Given $p_0^\prime$ and $p_s^\prime$, *Equation 6.64 (p. 270)* and *Equation 6.65 (p. 270)* are used to compute the velocity magnitude of the fluid at the inlet plane. Individual velocity components at the inlet are then derived using the direction vector components.

For compressible flow, the density at the inlet plane is defined by the ideal gas law in the form

$$\rho = \frac{p_s^\prime + p_{op}}{R T_s} \quad (6.66)$$

For multi-species gas mixtures, the specific gas constant, $R_i$ is computed from the species mass or mole fractions, $Y_i$ that you defined as boundary conditions at the pressure inlet boundary. The static temperature at the inlet, $T_y$, is computed from your input of total temperature, $T_0$, as

$$\frac{T_0}{T_y} = 1 + \frac{\gamma - 1}{2}M^2 \quad (6.67)$$

### 6.3.4. Velocity Inlet Boundary Conditions

Velocity inlet boundary conditions are used to define the flow velocity, along with all relevant scalar properties of the flow, at flow inlets. In this case, the total (or stagnation) pressure is not fixed but will rise (in response to the computed static pressure) to whatever value is necessary to provide the prescribed velocity distribution. This boundary condition is equally applicable to incompressible and compressible flows.
In special instances, a velocity inlet may be used in ANSYS Fluent to define the flow velocity at flow exits. (The scalar inputs are not used in such cases.) In such cases you must ensure that overall continuity is maintained in the domain.

For an overview of flow boundaries, see Flow Inlet and Exit Boundary Conditions (p. 256).

**6.3.4.1. Inputs at Velocity Inlet Boundaries**

**6.3.4.1.1. Summary**

You will enter the following information for a velocity inlet boundary:

- type of reference frame
- velocity magnitude and direction or velocity components
- swirl velocity (for 2D axisymmetric problems with swirl)
- static pressure
- temperature (for energy calculations)
- outflow gauge pressure (for calculations with the density-based solver)
- turbulence parameters (for turbulent calculations)
- radiation parameters (for calculations using the P-1 model, the DTRM, the DO model, or the surface-to-surface model)
- chemical species mass or mole fractions (for species calculations)
- mixture fraction and variance (for non-premixed or partially premixed combustion calculations)
- progress variable (for premixed or partially premixed combustion calculations)
- discrete phase boundary conditions (for discrete phase calculations)
- multiphase boundary conditions (for general multiphase calculations)

All values are entered in the Velocity Inlet Dialog Box (p. 2154) (Figure 6.19: The Velocity Inlet Dialog Box (p. 272)), which is opened from the Boundary Conditions task page (as described in Setting Cell Zone and Boundary Conditions (p. 204)).
6.3.4.1.2. Defining the Velocity

You can define the inflow velocity by specifying the velocity magnitude and direction, the velocity components, or the velocity magnitude normal to the boundary. If the cell zone adjacent to the velocity inlet is moving (that is, if you are using a moving reference frame, multiple reference frames, or sliding meshes), you can specify either relative or absolute velocities. For axisymmetric problems with swirl in ANSYS Fluent, you will also specify the swirl velocity.

The procedure for defining the inflow velocity is as follows:

1. Specify the flow direction by selecting **Magnitude and Direction**, **Components**, or **Magnitude, Normal to Boundary** in the **Velocity Specification Method** drop-down list.

2. If the cell zone adjacent to the velocity inlet is moving, you can choose to specify relative or absolute velocities by selecting **Relative to Adjacent Cell Zone** or **Absolute** in the **Reference Frame** drop-down list. If the adjacent cell zone is not moving, **Absolute** and **Relative to Adjacent Cell Zone** will be equivalent, so you need not visit the list.

3. If you are going to set the velocity magnitude and direction or the velocity components, and your geometry is 3D, choose **Cartesian (X, Y, Z)**, **Cylindrical (Radial, Tangential, Axial)**, or **Local Cylindrical (Radial, Tangential, Axial)** from the **Coordinate System** drop-down list. See **Defining the Flow Direction** (p. 265) for information about Cartesian, cylindrical, and local cylindrical coordinate systems.
4. Set the appropriate velocity parameters, as described below for each specification method.

**6.3.4.1.3. Setting the Velocity Magnitude and Direction**

If you selected *Magnitude and Direction* as the Velocity Specification Method in step 1 above, you will enter the magnitude of the velocity vector at the inflow boundary (the Velocity Magnitude) and the direction of the vector:

- If your geometry is 2D non-axisymmetric, or you chose in step 3 to use the *Cartesian* coordinate system, you will define the $X$, $Y$, and (in 3D) $Z$-Component of Flow Direction.

- If your geometry is 2D axisymmetric, or you chose in step 3 to use a *Cylindrical* coordinate system, enter the appropriate values of Radial, Axial, and (if you are modeling axisymmetric swirl or using cylindrical coordinates) Tangential-Component of Flow Direction.

- If you chose in step 3 to use a *Local Cylindrical* coordinate system, enter appropriate values for the Axial, Radial, and Tangential-Component of Flow Direction, and then specify the $X$, $Y$, and $Z$ components of the Axis Origin and the Axis Direction.

Figure 6.18: Cylindrical Velocity Components in 3D, 2D, and Axisymmetric Domains (p. 267) shows the vector components for these different coordinate systems.

**6.3.4.1.4. Setting the Velocity Magnitude Normal to the Boundary**

If you selected *Magnitude, Normal to Boundary* as the Velocity Specification Method in step 1 above, you will enter the magnitude of the velocity vector at the inflow boundary (the Velocity Magnitude).

**6.3.4.1.5. Setting the Velocity Components**

If you selected *Components* as the Velocity Specification Method in step 1 above, you will enter the components of the velocity vector at the inflow boundary as follows:

- If your geometry is 2D non-axisymmetric, or you chose in step 3 to use the Cartesian coordinate system, you will define the $X$, $Y$, and (in 3D) $Z$-Velocity.

- If your geometry is 2D axisymmetric without swirl, you will set the Radial and Axial-Velocity.

- If your model is 2D axisymmetric with swirl, you will set the Axial, Radial, and Swirl-Velocity, and (optionally) the Angular Velocity, as described below.

- If you chose in step 3 to use a Cylindrical coordinate system, you will set the Radial, Tangential, and Axial-Velocity, and (optionally) the Angular Velocity, as described below.

- If you chose in step 3 to use a Local Cylindrical coordinate system, you will set the Radial, Tangential, and Axial-Velocity, and (optionally) the Angular Velocity, as described below, and then specify the $X$, $Y$, and $Z$ component of the Axis Origin and the Axis Direction.

---

**Important**

Remember that positive values for $x$, $y$, and $z$ velocities indicate flow in the positive $x$, $y$, and $z$ directions. If flow enters the domain in the negative $x$ direction, for example, you will need to specify a negative value for the $x$ velocity. The same holds true for the radial, tan-
Cell Zone and Boundary Conditions

gential, and axial velocities. Positive radial velocities point radially out from the axis, positive axial velocities are in the direction of the axis vector, and positive tangential velocities are based on the right-hand rule using the positive axis.

6.3.4.1.6. Setting the Angular Velocity

If you chose Components as the Velocity Specification Method in step 1 above, and you are modeling axisymmetric swirl, you can specify the inlet Angular Velocity $\Omega$ in addition to the Swirl-Velocity. Similarly, if you chose Components as the Velocity Specification Method and you chose in step 3 to use a Cylindrical or Local Cylindrical coordinate system, you can specify the inlet Angular Velocity $\Omega$ in addition to the Tangential-Velocity.

If you specify $\Omega$, $v_\theta$ is computed for each face as $\Omega r$, where $r$ is the radial coordinate in the coordinate system defined by the rotation axis and origin. If you specify both the Swirl-Velocity and the Angular Velocity, or the Tangential-Velocity and the Angular Velocity, ANSYS Fluent will add $v_\theta$ and $\Omega r$ to get the swirl or tangential velocity at each face.

6.3.4.1.7. Defining Static Pressure

The static pressure (termed the Supersonic/Initial Gauge Pressure) must be specified if the inlet flow is supersonic or if you plan to initialize the solution based on the velocity inlet boundary conditions. Solution initialization is discussed in Initializing the Solution (p. 1445).

The Supersonic/Initial Gauge Pressure is ignored by ANSYS Fluent whenever the flow is subsonic. If you choose to initialize the flow based on the velocity inlet conditions, the Supersonic/Initial Gauge Pressure will be used in conjunction with the specified stagnation quantities to compute initial values according to isentropic relations.

Remember that the static pressure value you enter is relative to the operating pressure set in the Operating Conditions Dialog Box (p. 2095). Note the comments in Pressure Inputs and Hydrostatic Head (p. 263).

6.3.4.1.8. Defining the Temperature

For calculations in which the energy equation is being solved, you will set the static temperature of the flow at the velocity inlet boundary in the Thermal tab in the Temperature field.

6.3.4.1.9. Defining Outflow Gauge Pressure

If you are using the density-based solver, you can specify an Outflow Gauge Pressure for a velocity inlet boundary. If the flow exits the domain at any face on the boundary, that face will be treated as a pressure outlet with the pressure prescribed in the Outflow Gauge Pressure field.

6.3.4.1.10. Defining Turbulence Parameters

For turbulent calculations, there are several ways in which you can define the turbulence parameters. Instructions for deciding which method to use and determining appropriate values for these inputs are provided in Determining Turbulence Parameters (p. 257). Turbulence modeling in general is described in Modeling Turbulence (p. 695).
6.3.4.1.11. Defining Radiation Parameters

If you are using the P-1 radiation model, the DTRM, the DO model, or the surface-to-surface model, you will set the Internal Emissivity and (optionally) External Black Body Temperature. See Defining Boundary Conditions for Radiation (p. 798) for details. (The Rosseland radiation model does not require any boundary condition inputs.)

6.3.4.1.12. Defining Species Mass or Mole Fractions

If you are modeling species transport, you will set the species mass or mole fractions under Species Mole Fractions or Species Mass Fractions. For details, see Defining Cell Zone and Boundary Conditions for Species (p. 910).

6.3.4.1.13. Defining Non-Premixed Combustion Parameters

If you are using the non-premixed or partially premixed combustion model, you will set the Mean Mixture Fraction and Mixture Fraction Variance (and the Secondary Mean Mixture Fraction and Secondary Mixture Fraction Variance, if you are using two mixture fractions), as described in Defining Non-Premixed Boundary Conditions (p. 993).

6.3.4.1.14. Defining Premixed Combustion Boundary Conditions

If you are using the premixed or partially premixed combustion model, you will set the Progress Variable, as described in Setting Boundary Conditions for the Progress Variable (p. 1008).

6.3.4.1.15. Defining Discrete Phase Boundary Conditions

If you are modeling a discrete phase of particles, you can set the fate of particle trajectories at the velocity inlet. See Setting Boundary Conditions for the Discrete Phase (p. 1189) for details.

6.3.4.1.16. Defining Multiphase Boundary Conditions

If you are using the VOF, mixture, or Eulerian model for multiphase flow, you will need to specify volume fractions for secondary phases and (for some models) additional parameters. See Defining Multiphase Cell Zone and Boundary Conditions (p. 1260) for details.

6.3.4.2. Default Settings at Velocity Inlet Boundaries

Default settings (in SI) for velocity inlet boundary conditions are as follows:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Temperature</td>
<td>300</td>
</tr>
<tr>

</tbody>
</table>
6.3.4.3. Calculation Procedure at Velocity Inlet Boundaries

ANSYS Fluent uses your boundary condition inputs at velocity inlets to compute the mass flow into the domain through the inlet and to compute the fluxes of momentum, energy, and species through the inlet. This section describes these calculations for the case of flow entering the domain through the velocity inlet boundary and for the less common case of flow exiting the domain through the velocity inlet boundary.

6.3.4.3.1. Treatment of Velocity Inlet Conditions at Flow Inlets

When your velocity inlet boundary condition defines flow entering the physical domain of the model, ANSYS Fluent uses both the velocity components and the scalar quantities that you defined as boundary conditions to compute the inlet mass flow rate, momentum fluxes, and fluxes of energy and chemical species.

The mass flow rate entering a fluid cell adjacent to a velocity inlet boundary is computed as

\[
\dot{m} = \int \rho \vec{V} \cdot d\vec{A}
\]

Note that only the velocity component normal to the control volume face contributes to the inlet mass flow rate.

6.3.4.3.2. Treatment of Velocity Inlet Conditions at Flow Exits

Sometimes a velocity inlet boundary is used where flow exits the physical domain. This approach might be used, for example, when the flow rate through one exit of the domain is known or is to be imposed on the model.

Important

In such cases you must ensure that overall continuity is maintained in the domain.

In the pressure-based solver, when flow exits the domain through a velocity inlet boundary ANSYS Fluent uses the boundary condition value for the velocity component normal to the exit flow area. It does not use any other boundary conditions that you have input. Instead, all flow conditions except the normal velocity component are assumed to be those of the upstream cell.

In the density-based solver, if the flow exits the domain at any face on the boundary, that face will be treated as a pressure outlet with the pressure prescribed in the Outflow Gauge Pressure field.

6.3.4.3.3. Density Calculation

Density at the inlet plane is either constant or calculated as a function of temperature, pressure, and/or species mass/mole fractions, where the mass or mole fractions are the values you entered as an inlet condition.

6.3.5. Mass Flow Inlet Boundary Conditions

Mass flow boundary conditions can be used in ANSYS Fluent to provide a prescribed mass flow rate or mass flux distribution at an inlet. As with a velocity inlet, specifying the mass flux permits the total
pressure to vary in response to the interior solution. This is in contrast to the pressure inlet boundary condition (see Pressure Inlet Boundary Conditions (p. 262)), where the total pressure is fixed while the mass flux varies. However, unlike a velocity inlet, the mass flow inlet is equally applicable to incompressible and compressible flows.

A mass flow inlet is often used when it is more important to match a prescribed mass flow rate than to match the total pressure of the inflow stream. An example is the case of a small cooling jet that is bled into the main flow at a fixed mass flow rate, while the velocity of the main flow is governed primarily by a (different) pressure inlet/outlet boundary condition pair. A mass flow inlet boundary condition can also be used as an outflow by specifying the flow direction away from the solution domain.

6.3.5.1. Limitations and Special Considerations

- The adjustment of inlet total pressure might result in a slower convergence, so if both the pressure inlet boundary condition and the mass flow inlet boundary condition are acceptable choices, you should choose the former.

- It is not necessary to use mass flow inlets in incompressible flows because when density is constant, velocity inlet boundary conditions will fix the mass flow.

- A mass flow boundary operating as an outflow has the following limitations:
  - It is available for single-phase flow only.
  - It is not available with the VOF, mixture, and Eulerian multiphase models in the pressure-based solver.
  - It is not available with the Wet Steam model in the density-based solver.

For an overview of flow boundaries, see Flow Inlet and Exit Boundary Conditions (p. 256).

6.3.5.2. Inputs at Mass Flow Inlet Boundaries

6.3.5.2.1. Summary

You will enter the following information for a mass flow inlet boundary:

- type of reference frame
- mass flow rate, mass flux, or (primarily for the mixing plane model) mass flux with average mass flux
- total (stagnation) temperature
- static pressure
- flow direction
- turbulence parameters (for turbulent calculations)
- radiation parameters (for calculations using the P-1 model, the DTRM, the DO model, or the surface-to-surface model)
- chemical species mass or mole fractions (for species calculations)
- mixture fraction and variance (for non-premixed or partially premixed combustion calculations)
• progress variable (for premixed or partially premixed combustion calculations)

• discrete phase boundary conditions (for discrete phase calculations)

• open channel flow parameters (for open channel flow calculations using the VOF multiphase model)

All values are entered in the Mass-Flow Inlet Dialog Box (p. 2124) (Figure 6.20: The Mass-Flow Inlet Dialog Box (p. 278)), which is opened from the Boundary Conditions task page (as described in Setting Cell Zone and Boundary Conditions (p. 204)). Note that open channel boundary condition inputs are described in Modeling Open Channel Flows (p. 1275).

Figure 6.20: The Mass-Flow Inlet Dialog Box

6.3.5.2.2. Selecting the Reference Frame

You will have the option to specify the mass flow boundary conditions either in the absolute or relative reference frame, when the cell zone adjacent to the mass flow inlet is moving. For such a case, choose Absolute (the default) or Relative to Adjacent Cell Zone in the Reference Frame drop-down list. If the cell zone adjacent to the mass flow inlet is not moving, both formulations are equivalent.
6.3.5.2.3. Defining the Mass Flow Rate or Mass Flux

You can specify the mass flow rate through the inlet zone and have ANSYS Fluent convert this value to mass flux, or specify the mass flux directly. For cases where the mass flux varies across the boundary, you can also specify an average mass flux; see below for more information about this specification method.

You can define the mass flux or mass flow rate using a profile or a user-defined function.

The inputs for mass flow rate or flux are as follows:

2. If you selected Mass Flow Rate (the default), set the prescribed mass flow rate in the Mass Flow Rate field when constant is selected from the drop-down list. Otherwise, select your hooked UDF or transient profile.

   **Important**

   The hooked UDF or transient profile can only be used to provide time-varying specification of mass flow rate. Therefore, the transient solver must be used to run the simulation. Note that the variation of profile with position in space is not applicable with this hookup.

   See DEFINE_PROFILE in the UDF Manual for an example of a mass flow inlet UDF.

   **Important**

   Note that for axisymmetric problems, this mass flow rate is the flow rate through the entire (2π-radian) domain, not through a 1-radian slice.

3. If you selected Mass Flux, set the prescribed mass flux in the Mass Flux field, or select your hooked UDF or profile.

4. If you selected Mass Flux with Average Mass Flux, set the prescribed mass flux and average mass flux in the Mass Flux and Average Mass Flux fields.

6.3.5.2.4. More About Mass Flux and Average Mass Flux

As noted above, you can specify an average mass flux with the mass flux. If, for example, you specify a mass flux profile such that the average mass flux integrated over the zone area is 4.7, but you actually want to have a total mass flux of 5, you can keep the profile unchanged, and specify an average mass flux of 5. ANSYS Fluent will maintain the profile shape but adjust the values so that the resulting mass flux across the boundary is 5.

The mass flux with average mass flux specification method is also used by the mixing plane model described in The Mixing Plane Model (p. 547). If the mass flow inlet boundary is going to represent one of the mixing planes, then you do not need to specify the mass flux or flow rate; you can keep the default Mass Flow Rate of 1. When you create the mixing plane later on in the problem setup, ANSYS Fluent will automatically select the Mass Flux with Average Mass Flux method in the Mass-Flow Inlet dialog box and set the Average Mass Flux to the value obtained by integrating the mass flux profile for the
upstream zone. This will ensure that mass is conserved between the upstream zone and the downstream (mass flow inlet) zone.

6.3.5.2.5. Defining the Total Temperature

Enter the value for the total (stagnation) temperature of the inflow stream in the **Total Temperature** field in the **Thermal** tab.

The total temperature is specified either in the absolute reference frame or relative to the adjacent cell zone, depending on your setting for the **Reference Frame**.

For the Eulerian multiphase model, the total temperature, and mass flux components need to be specified for the individual phases. The **Reference Frame (Relative to Adjacent Cell Zone or Absolute)** for each of the phases is the same as the reference frame selected for the mixture phase.

---

**Important**

Note that you can only set the reference frame for the mixture, however, the total temperature can only be set for the individual phases.

---

**Important**

- If the flow is incompressible, then the temperature assigned in the **Mass-Flow Inlet** dialog box is considered to be the static temperature.

- For the mixture multiphase model, if a boundary allows a combination of compressible and incompressible phases to enter the domain, then the temperature assigned in the **Mass-Flow Inlet** dialog box is considered to be the static temperature at that boundary. If a boundary allows *only a compressible phase* to enter the domain, then the temperature assigned in the **Mass-Flow Inlet** dialog box is the total temperature (relative/absolute) at that boundary. The total temperature depends on the **Reference Frame** option selected in the **Mass-Flow Inlet** dialog box.

- For the VOF multiphase model, if a boundary allows a *compressible phase* to enter the domain, then the temperature assigned in the **Mass-Flow Inlet** dialog box is considered to be the total temperature at that boundary. The total temperature (relative/absolute) depends on the **Reference Frame** option chosen in the dialog box. Otherwise, the temperature assigned to the boundary is considered to be the static temperature at the boundary.

- For the Eulerian multiphase model, if a boundary allows a mixture of compressible and incompressible phases in the domain, then the temperature of each of the phases is the total or static temperature, depending on whether the phase is compressible or incompressible. Total temperature (relative/absolute) depends on the **Reference Frame** option chosen in the **Mass-Flow Inlet** dialog box.

---

6.3.5.2.6. Defining Static Pressure

The static pressure (termed the **Supersonic/Initial Gauge Pressure**) must be specified if the inlet flow is supersonic or if you plan to initialize the solution based on the pressure inlet boundary conditions. Solution initialization is discussed in [Initializing the Solution (p. 1445)](#).
The **Supersonic/Initial Gauge Pressure** is ignored by ANSYS Fluent whenever the flow is subsonic. If you choose to initialize the flow based on the mass flow inlet conditions, the **Supersonic/Initial Gauge Pressure** will be used in conjunction with the specified stagnation quantities to compute initial values according to isentropic relations.

Remember that the static pressure value you enter is relative to the operating pressure set in the **Operating Conditions Dialog Box** (p. 2095). Note the comments in **Pressure Inputs and Hydrostatic Head** (p. 263) regarding hydrostatic pressure.

### 6.3.5.2.7. Defining the Flow Direction

You can define the flow direction at a mass flow inlet explicitly, or you can define the flow to be normal to the boundary.

The procedure for defining the flow direction is as follows, referring to **Figure 6.20: The Mass-Flow Inlet Dialog Box** (p. 278):

1. Specify the flow direction by selecting **Direction Vector**, **Normal to Boundary**, or **Outward Normals** in the **Direction Specification Method** drop-down list.

2. If you selected **Direction Vector** and your geometry is 2D, go to the next step. If your geometry is 3D, choose **Cartesian (X, Y, Z)**, **Cylindrical (Radial, Tangential, Axial)**, **Local Cylindrical (Radial, Tangential, Axial)**, or **Local Cylindrical Swirl** in the **Coordinate System** drop-down list. See **Defining the Flow Direction** (p. 265) for information about Cartesian, cylindrical, local cylindrical, and local cylindrical swirl coordinate systems.

3. If you selected **Direction Vector**, set the vector components as follows:

   - If your geometry is 2D non-axisymmetric, or you chose to use a 3D **Cartesian** coordinate system, enter appropriate values for the **X**, **Y**, and (in 3D) **Z-Component of Flow Direction**.

   - If your geometry is 2D axisymmetric, or you chose to use a 3D **Cylindrical** coordinate system, enter appropriate values for the **Axial**, **Radial**, and (if you are modeling swirl or using cylindrical coordinates) **Tangential-Component of Flow Direction**.

   - If you chose to use a 3D **Local Cylindrical** coordinate system, enter appropriate values for the **Axial**, **Radial**, and **Tangential-Component of Flow Direction**, and then specify the **X**, **Y**, and **Z** components of **Axis Origin** and the **Axis Direction**.

   - If you chose to use a 3D **Local Cylindrical Swirl** coordinate system, enter appropriate values for the **Axial** and **Radial-Component of Flow Direction** in the axial and radial planes, and the **Tangential-Velocity**. Specify the **X**, **Y**, and **Z** components of the **Axis Origin** and the **Axis Direction**.

**Important**

**Local Cylindrical Swirl** should not be used for open channel boundary conditions and on the mixing plane boundaries, while using the mixing plane model.
4. If you selected **Normal to Boundary**, there are no additional inputs for flow direction.

**Important**

*Note that if you are modeling axisymmetric swirl, the flow direction will be normal to the boundary; that is, there will be no swirl component at the boundary for axisymmetric swirl.*

5. If **Outward Normals** is selected, then the mass flow boundary will operate as an outflow, pumping flow out of the domain with the rate specified in the **Mass Flow Specification Method**. If the mass flow rate is specified, then by default, the fluxes on the boundary will be allowed to vary to preserve the flow profile out of the domain. At convergence, the total mass flow rate should match the specified value. If constant mass flux is needed rather than the default variable fluxes to preserve the profiles, then you can do so via the text command `define/boundary-conditions/bc-settings/mass-flow`. Answer **no** when asked to preserve profile while flow leaves.

**Important**

*The mass flow boundary can also operate as an outflow using the **Direction Vector** flow specification method if the flow components are pointing away from the boundary.*

### 6.3.5.2.8. Defining Turbulence Parameters

For turbulent calculations, there are several ways in which you can define the turbulence parameters. Instructions for deciding which method to use and determining appropriate values for these inputs are provided in Determining Turbulence Parameters (p. 257). Turbulence modeling is described in Modeling Turbulence (p. 695).

### 6.3.5.2.9. Defining Radiation Parameters

If you are using the P-1 radiation model, the DTRM, the DO model, or the surface-to-surface model, you will set the **Internal Emissivity** and (optionally) **External Black Body Temperature**. See Defining Boundary Conditions for Radiation (p. 798) for details. (The Rosseland radiation model does not require any boundary condition inputs.)

### 6.3.5.2.10. Defining Species Mass or Mole Fractions

If you are modeling species transport, you will set the species mass or mole fractions under **Species Mole Fractions** or **Species Mass Fractions**. For details, see Defining Cell Zone and Boundary Conditions for Species (p. 910).

### 6.3.5.2.11. Defining Non-Premixed Combustion Parameters

If you are using the non-premixed or partially premixed combustion model, you will set the **Mean Mixture Fraction** and **Mixture Fraction Variance** (and the **Secondary Mean Mixture Fraction** and **Secondary Mixture Fraction Variance**, if you are using two mixture fractions), as described in Defining Non-Premixed Boundary Conditions (p. 993).
6.3.5.2.12. Defining Premixed Combustion Boundary Conditions

If you are using the premixed or partially premixed combustion model, you will set the Progress Variable, as described in Setting Boundary Conditions for the Progress Variable (p. 1008).

6.3.5.2.13. Defining Discrete Phase Boundary Conditions

If you are modeling a discrete phase of particles, you can set the fate of particle trajectories at the mass flow inlet. See Setting Boundary Conditions for the Discrete Phase (p. 1189) for details.

6.3.5.2.14. Defining Open Channel Boundary Conditions

If you are using the VOF model for multiphase flow and modeling open channel flows, you will need to specify the Free Surface Level, Bottom Level, and additional parameters. See Modeling Open Channel Flows (p. 1275) for details.

6.3.5.3. Default Settings at Mass Flow Inlet Boundaries

Default settings (in SI) for mass flow inlet boundary conditions are as follows:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mass Flow-Rate</td>
<td>1</td>
</tr>
<tr>
<td>Total Temperature</td>
<td>300</td>

<td>0</td>
</tr>
<tr>
<td>X-Component of Flow Direction</td>
<td>1</td>
</tr>
<tr>
<td>Y-Component of Flow Direction</td>
<td>0</td>
</tr>
<tr>
<td>Z-Component of Flow Direction</td>
<td>0</td>
</tr>
<tr>
<td>Turbulent Intensity</td>
<td>5%</td>
</tr>
<tr>
<td>Turbulent Viscosity Ratio</td>
<td>10</td>
</tr>
</tbody>
</table>

6.3.5.4. Calculation Procedure at Mass Flow Inlet Boundaries

When mass flow boundary conditions are used for an inlet zone, a velocity is computed for each face in that zone, and this velocity is used to compute the fluxes of all relevant solution variables into the domain. With each iteration, the computed velocity is adjusted so that the correct mass flow value is maintained.

To compute this velocity, your inputs for mass flow rate, flow direction, static pressure, and total temperature are used.

There are two ways to specify the mass flow rate. The first is to specify the total mass flow rate, \( \dot{m} \), for the inlet. The second is to specify the mass flux, \( \rho v_n \) (mass flow rate per unit area). If a total mass flow rate is specified, ANSYS Fluent converts it internally to a uniform mass flux by dividing the mass flow rate by the total inlet area:

\[
\rho v_n = \frac{\dot{m}}{A} \tag{6.69}
\]

If the direct mass flux specification option is used, the mass flux can be varied over the boundary by using profile files or user-defined functions. If the average mass flux is also specified (either explicitly by you or automatically by ANSYS Fluent), it is used to correct the specified mass flux profile, as described earlier in this section.
Once the value of $\rho v_n$ at a given face has been determined, the density, $\rho$, at the face must be determined in order to find the normal velocity, $v_n$. The manner in which the density is obtained depends upon whether the fluid is modeled as an ideal gas or not. Each of these cases is examined below.

### 6.3.5.4.1. Flow Calculations at Mass Flow Boundaries for Ideal Gases

If the fluid is an ideal gas, the static temperature and static pressure are required to compute the density:

$$p = \rho RT$$  \hspace{1cm} (6.70)

If the inlet is supersonic, the static pressure used is the value that has been set as a boundary condition. If the inlet is subsonic, the static pressure is extrapolated from the cells inside the inlet face.

The static temperature at the inlet is computed from the total enthalpy, which is determined from the total temperature that has been set as a boundary condition. The total enthalpy is given by

$$h_0(T_0) = h(T) + \frac{1}{2}v^2$$  \hspace{1cm} (6.71)

where the velocity magnitude is related to the mass flow rate given by Equation 6.69 (p. 283) and the known user-specified flow direction vector. Using Equation 6.70 (p. 284) to relate density to the (known) static pressure and (unknown) temperature, Equation 6.71 (p. 284) can be solved to obtain the static temperature.

When the mass flow is used as an outflow with the profile preserving feature, a scaling factor of the specified mass flow rate over the computed mass flow rate at the boundary is used to scale the normal face velocities at the boundary. The other velocity components will be extrapolated from the interior. Flow variables such as pressure, temperature, species, or other scalar quantities will be also extrapolated from adjacent cell centers.

### 6.3.5.4.2. Flow Calculations at Mass Flow Boundaries for Incompressible Flows

When you are modeling incompressible flows, the static temperature is equal to the total temperature. The density at the inlet is either constant or readily computed as a function of the temperature and (optionally) the species mass or mole fractions. The velocity is then computed using Equation 6.69 (p. 283).

### 6.3.5.4.3. Flux Calculations at Mass Flow Boundaries

To compute the fluxes of all variables at the inlet, the flux velocity, $v_n$, is used along with the inlet value of the variable in question. For example, the flux of mass is $\rho v_n$, and the flux of turbulence kinetic energy is $\rho k v_n$. These fluxes are used as boundary conditions for the corresponding conservation equations during the course of the solution.

### 6.3.6. Inlet Vent Boundary Conditions

Inlet vent boundary conditions are used to model an inlet vent with a specified loss coefficient, flow direction, and ambient (inlet) pressure and temperature.

#### 6.3.6.1. Inputs at Inlet Vent Boundaries

You will enter the following information for an inlet vent boundary:

- type of reference frame
Boundary Conditions

- total (stagnation) pressure
- total (stagnation) temperature
- flow direction
- static pressure
- turbulence parameters (for turbulent calculations)
- radiation parameters (for calculations using the P-1 model, the DTRM, the DO model, or the surface-to-surface model)
- chemical species mass or mole fractions (for species calculations)
- mixture fraction and variance (for non-premixed or partially premixed combustion calculations)
- progress variable (for premixed or partially premixed combustion calculations)
- discrete phase boundary conditions (for discrete phase calculations)
- multiphase boundary conditions (for general multiphase calculations)
- loss coefficient
- open channel flow parameters (for open channel flow calculations using the VOF multiphase model)

All values are entered in the Inlet Vent Dialog Box (p. 2113) (Figure 6.21: The Inlet Vent Dialog Box (p. 286)), which is opened from the Boundary Conditions task page (as described in Setting Cell Zone and Boundary Conditions (p. 204)).

The first 12 items listed above are specified in the same way that they are specified at pressure inlet boundaries. See Inputs at Pressure Inlet Boundaries (p. 262) for details. Specification of the loss coefficient is described here. Open channel boundary condition inputs are described in Modeling Open Channel Flows (p. 1275).
6.3.6.1.1. Specifying the Loss Coefficient

An inlet vent is considered to be infinitely thin, and the pressure drop through the vent is assumed to be proportional to the dynamic head of the fluid, with an empirically determined loss coefficient that you supply. That is, the pressure drop, $\Delta p$, varies with the normal component of velocity through the vent, $v$, as follows:

$$\Delta p = k_L \frac{1}{2} \rho v^2$$  \hspace{1cm} (6.72)

where $\rho$ is the fluid density, and $k_L$ is the non-dimensional loss coefficient.

**Important**

$\Delta p$ is the pressure drop in the direction of the flow; therefore the vent will appear as a resistance even in the case of backflow.

You can define the **Loss-Coefficient** across the vent as a constant, polynomial, piecewise-linear, or piecewise-polynomial function of the normal velocity. The dialog boxes for defining these functions
are the same as those used for defining temperature-dependent properties. See Defining Properties Using Temperature-Dependent Functions (p. 412) for details.

### 6.3.7. Intake Fan Boundary Conditions

Intake fan boundary conditions are used to model an external intake fan with a specified pressure jump, flow direction, and ambient (intake) pressure and temperature.

#### 6.3.7.1. Inputs at Intake Fan Boundaries

You will enter the following information for an intake fan boundary:

- type of reference frame
- total (stagnation) pressure
- total (stagnation) temperature
- flow direction
- static pressure
- turbulence parameters (for turbulent calculations)
- radiation parameters (for calculations using the P-1 model, the DTRM, the DO model, or the surface-to-surface model)
- chemical species mass or mole fractions (for species calculations)
- mixture fraction and variance (for non-premixed or partially premixed combustion calculations)
- progress variable (for premixed or partially premixed combustion calculations)
- discrete phase boundary conditions (for discrete phase calculations)
- multiphase boundary conditions (for general multiphase calculations)
- pressure jump
- open channel flow parameters (for open channel flow calculations using the VOF multiphase model)

All values are entered in the Intake Fan Dialog Box (p. 2118) (shown in Figure 6.22: The Intake Fan Dialog Box (p. 288)), which is opened from the Boundary Conditions task page (as described in Setting Cell Zone and Boundary Conditions (p. 204)).

The first 12 items listed above are specified in the same way that they are specified at pressure inlet boundaries. See Inputs at Pressure Inlet Boundaries (p. 262) for details. Specification of the pressure jump is described here. Open channel boundary condition inputs are described in Modeling Open Channel Flows (p. 1275).
6.3.7.1.1. Specifying the Pressure Jump

An intake fan is considered to be infinitely thin, and the discontinuous pressure rise across it is specified as a function of the velocity through the fan. In the case of reversed flow, the fan is treated like an outlet vent with a loss coefficient of unity.

You can define the Pressure-Jump across the fan as a constant, polynomial, piecewise-linear, or piecewise-polynomial function of the normal velocity. The dialog boxes for defining these functions are the same as those used for defining temperature-dependent properties. See Defining Properties Using Temperature-Dependent Functions (p. 412) for details.
6.3.8. Pressure Outlet Boundary Conditions

Pressure outlet boundary conditions require the specification of a static (gauge) pressure at the outlet boundary. The value of the specified static pressure is used only while the flow is subsonic. Should the flow become locally supersonic, the specified pressure will no longer be used; pressure will be extrapolated from the flow in the interior. All other flow quantities are extrapolated from the interior.

A set of “backflow” conditions is also specified should the flow reverse direction at the pressure outlet boundary during the solution process. Convergence difficulties will be minimized if you specify realistic values for the backflow quantities.

Several options in ANSYS Fluent exist, where a radial equilibrium outlet boundary condition can be used (see Defining Static Pressure (p. 290) and a target mass flow rate for pressure outlets (see Target Mass Flow Rate Option (p. 296) for details) can be specified.

For an overview of flow boundaries, see Flow Inlet and Exit Boundary Conditions (p. 256).

6.3.8.1. Inputs at Pressure Outlet Boundaries

6.3.8.1.1. Summary

You will enter or select the following information for a pressure outlet boundary:
- static pressure
- backflow conditions
  - total (stagnation) temperature (for energy calculations)
  - backflow direction specification method
  - turbulence parameters (for turbulent calculations)
  - chemical species mass or mole fractions (for species calculations)
  - mixture fraction and variance (for non-premixed or partially premixed combustion calculations)
  - progress variable (for premixed or partially premixed combustion calculations)
  - multiphase boundary conditions (for general multiphase calculations)
- radiation parameters (for calculations using the P-1 model, the DTRM, the DO model, or the surface-to-surface model)
- discrete phase boundary conditions (for discrete phase calculations)
- open channel flow parameters (for open channel flow calculations using the VOF multiphase model)
- radial equilibrium pressure distribution
- average pressure specification (not available for multiphase flows)
- target mass flow rate (not available for multiphase flows)
• non-reflecting boundary (for compressible density-based solver, see General Non-Reflecting Boundary Conditions (p. 362) for details)

All values are entered in the Pressure Outlet Dialog Box (p. 2146) (Figure 6.23: The Pressure Outlet Dialog Box (p. 290)), which is opened from the Boundary Conditions task page (as described in Setting Cell Zone and Boundary Conditions (p. 204)). Note that open channel boundary condition inputs are described in Modeling Open Channel Flows (p. 1275).

**Figure 6.23: The Pressure Outlet Dialog Box**

![Pressure Outlet Dialog Box]

### 6.3.8.1.2. Defining Static Pressure

To set the static pressure at the pressure outlet boundary, enter the appropriate value for **Gauge Pressure** in the Pressure Outlet dialog box. This value will be used for subsonic flow only. Should the flow become locally supersonic, the pressure will be extrapolated from the upstream conditions.

Remember that the static pressure value you enter is relative to the operating pressure set in the Operating Conditions Dialog Box (p. 2095). Refer to Pressure Inputs and Hydrostatic Head (p. 263) regarding hydrostatic pressure.

ANSYS Fluent also provides an option to use a radial equilibrium outlet boundary condition. This option is used to model the exit flow in turbomachinery flow problems. To turn on this option, enable **Radial Equilibrium Pressure Distribution**. When this feature is active, the specified gauge pressure applies only to the position of minimum radius (relative to the axis of rotation) at the boundary. The static
pressure on the rest of the zone is calculated from the assumption that radial velocity is negligible, so that the pressure gradient is given by

\[ \frac{\partial p}{\partial r} = \frac{\rho v_\theta^2}{r} \]

where \( r \) is the distance from the axis of rotation and \( v_\theta \) is the tangential velocity. Note that this boundary condition can be used even if the rotational velocity is zero. For example, it could be applied to the calculation of the flow through an annulus containing guide vanes.

---

**Important**

Note that the radial equilibrium outlet condition is available only for 3D and axisymmetric swirl calculations.

---

ANSYS Fluent also provides an option to use an **Average Pressure Specification** method at the pressure outlet boundary. This option allows the pressure along the outlet boundary to vary, but maintain an average equivalent to the specified value in the **Gauge Pressure** input field. The pressure variation allowed in this boundary implementation slightly diminishes the reflectivity of the boundary as compared with the default uniform pressure specification. In the density-based solver two averaging methods are available, strong and weak averaging. The average pressure specification in the pressure-based solver is equivalent to the strong pressure averaging in the density-based solver. For more details, see Calculation Procedure at Pressure Outlet Boundaries (p. 293).

---

**Note**

The **Average Pressure Specification** option is not available if the **Radial Equilibrium Pressure Distribution** option is enabled.

---

### 6.3.8.1.3. Defining Backflow Conditions

Backflow properties consistent with the models you are using will appear in the **Pressure Outlet** dialog box. The specified values will be used only if flow is pulled in through the outlet.

- The **Backflow Total Temperature** (in the **Thermal** tab) should be set for problems involving energy calculation.

- When the direction of the backflow re-entering the computational domain is known, and deemed to be relevant to the flow field solution, you can specify it choosing one of the options available in the **Backflow Direction Specification Method** drop-down list. The default value for this field is **Normal to Boundary**, and requires no further input. If you choose **Direction Vector**, the dialog box will expand to show the inputs for the components of the direction vector for the backflow, and if you are running the 3D version of ANSYS Fluent, the dialog box will display a **Coordinate System** drop-down list. If you choose **From Neighboring Cell**, ANSYS Fluent will determine the direction of the backflow using the direction of the flow in the cell layer adjacent to the pressure outlet.

- For turbulent calculations, there are several ways in which you can define the turbulence parameters. Instructions for deciding which method to use in determining appropriate values for these inputs are provided in Determining Turbulence Parameters (p. 257). Turbulence modeling in general is described in Modeling Turbulence (p. 695).
If you are modeling species transport, you will set the backflow species mass or mole fractions under **Species Mass Fractions** or **Species Mole Fractions**. For details, see Defining Cell Zone and Boundary Conditions for Species (p. 910).

If you are modeling combustion using the non-premixed or partially premixed combustion model, you will set the backflow mixture fraction and variance values. See Defining Non-Premixed Boundary Conditions (p. 993) for details.

If you are modeling combustion using the premixed or partially premixed combustion model, you will set the backflow **Progress Variable** value. See Setting Boundary Conditions for the Progress Variable (p. 1008) for details.

If you are using the VOF, mixture, or Eulerian model for multiphase flow, you will need to specify volume fractions for secondary phases and (for some models) additional parameters. See Defining Multiphase Cell Zone and Boundary Conditions (p. 1260) for details.

If backflow occurs, the pressure you specified as the **Gauge Pressure** will be used as total pressure, so you need not specify a backflow pressure value explicitly. The flow direction will be based on your specification of the direction vector.

If the cell zone adjacent to the pressure outlet is moving (that is, if you are using a moving reference frame, multiple reference frames, mixing planes, or sliding meshes) and you are using the pressure-based solver, the velocity in the dynamic contribution to total pressure (see Equation 6.59 (p. 264)) will be absolute or relative to the motion of the cell zone, depending on whether or not the **Absolute velocity formulation** is selected in the **General** task page. For the density-based solver, the velocity in Equation 6.59 (p. 264) (or the Mach number in Equation 6.60 (p. 264)) is always in the absolute frame.

---

**Important**

Even if no backflow is expected in the converged solution, you should always set realistic values to minimize convergence difficulties in the event that backflow does occur during the calculation.

---

### 6.3.8.1.4. Defining Radiation Parameters

If you are using the P-1 radiation model, the DTRM, the DO model, or the surface-to-surface model, you will set the **Internal Emissivity** and (optional) **External Black Body Temperature Method**. See Defining Boundary Conditions for Radiation (p. 798) for details. (The Rosseland radiation model does not require any boundary condition inputs.)

### 6.3.8.1.5. Defining Discrete Phase Boundary Conditions

If you are modeling a discrete phase of particles, you can set the fate of particle trajectories at the pressure outlet. See Setting Boundary Conditions for the Discrete Phase (p. 1189) for details.

### 6.3.8.1.6. Defining Open Channel Boundary Conditions

If you are using the VOF model for multiphase flow and modeling open channel flows, you will need to specify the **Free Surface Level**, **Bottom Level**, and additional parameters. See Modeling Open Channel Flows (p. 1275) for details.
6.3.8.2. Default Settings at Pressure Outlet Boundaries

Default settings (in SI) for pressure outlet boundary conditions are as follows:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Gauge Pressure</strong></td>
<td>0</td>
</tr>
<tr>
<td><strong>Backflow Total Temperature</strong></td>
<td>300</td>
</tr>
<tr>
<td><strong>Backflow Turbulent Intensity</strong></td>
<td>5%</td>
</tr>
<tr>
<td><strong>Backflow Turbulent Viscosity Ratio</strong></td>
<td>10</td>
</tr>
</tbody>
</table>

6.3.8.3. Calculation Procedure at Pressure Outlet Boundaries

At pressure outlets, ANSYS Fluent uses the boundary condition pressure you input as the static pressure of the fluid at the outlet plane, \( P_{so} \), and extrapolates all other conditions from the interior of the domain.

6.3.8.3.1. Pressure-Based Solver Implementation

In the pressure-based solver, by default, the face pressure at the boundary is the same as the value specified in the Pressure Outlet dialog box. When the Average Pressure Specification option is enabled, the face pressure value \( P_f \) for subsonic flows at the outlet boundary is computed using the following expressions:

\[
P_f = 0.5 \left( P_c + P_e \right) + dp
\]  

(6.74)

where

\[
P_c = \text{interior cell pressure at neighboring exit face, } f
\]

\[
P_e = \text{specified exit pressure}
\]

\[
dp = \text{difference in the pressure value between the specified pressure } P_e \text{ and the latest average pressure for the boundary defined by Equation 6.75 (p. 293)}
\]

\[
dp = P_e - \frac{\sum_{f} 0.5 \left( P_c + P_e \right) A_f}{\sum_{f} A_f}
\]  

(6.75)

Typically, this averaging option should be used when the flow at the boundary exit is subsonic. If the flow is fully supersonic, then the Average Pressure Specification has no effect. If the flow at the exit is partially supersonic, then the face pressure value at the supersonic flow location will be extrapolated from the interior cells and will be included in the averaging procedure.

---

**Note**

If a geometric opening was modeled as a multiple pressure-outlet boundary condition with the average pressure specification, then the averaging is applied on each individual boundary condition and not over the entire geometric opening.

The limitations that exist when using the Average Pressure Specification option are listed below:

- The Average Pressure Specification option is not available when Radial Equilibrium Pressure Distribution is enabled.
• If the pressure outlet boundary is part of the mixing plane model pair, then the **Average Pressure Specification** option will not be available for that particular boundary zone.

• The **Average Pressure Specification** option is not available with multiphase flows.

• If a profile is specified for the **Gauge Pressure** field instead of a constant value, then the **Average Pressure Specification** will not be applied.

### 6.3.8.3.2. Density-Based Solver Implementation

In the density-based solver, by default, the face pressure at the boundary is the same as the value specified in the Pressure Outlet dialog box. When the **Average Pressure Specification** option is enabled, you can set one of two pressure averaging methods:

1. **Strong Averaging**
2. **Weak Averaging**

When the weak averaging method is used and the flow is subsonic, the pressure at the faces of the outlet boundary is computed using a weighted average of the left and right state of the face boundary. This weighting is a blend of fifth-order polynomials based on the exit face normal Mach number \([51]\) (p. 2559). Therefore, the face pressure \(P_f\) is a function of \((P_c, P_e, M_n)\), where \(P_c\) is the interior cell pressure neighboring the exit face \(f\), \(P_e\) is the specified exit pressure, and \(M_n\) is the face normal Mach number.

**Figure 6.24: Pressures at the Face of a Pressure Outlet Boundary**

For incompressible flows, the face pressure is computed as an average between the specified pressure and the interior pressure.

\[
P_f = 0.5 \left( P_c + P_e \right)
\] 

(6.76)
In this boundary implementation, the exit pressure is not constant along the pressure outlet boundary. However, upon flow convergence, the average boundary pressure will be close to the specified static exit pressure.

In general the weak average pressure enforcement works well in most flow situations. However, for cases where the computed average pressure value does not match the specified pressure value at the boundary (typically this happen when we have a coarse mesh and stretched cells near the pressure-outlet boundary) then the strong average pressure enforcement can be used to guarantee the specified pressure equal to the boundary average pressure. The strong enforcement is achieved by adding locally the difference in pressure value between the latest average pressure for the boundary and the face pressure obtained from weak enforcement.

\[ P_f = P_{f, weak} + dp \]  
(6.77)

where, \( P_{f, weak} \) is computed on the boundary faces as described earlier for weak averaging method using the fifth-order polynomial for compressible flow and as in Equation 6.76 for incompressible flow.

Therefore for weak averaging:
\[ dp = 0 \]  
(6.78)

While for strong averaging:
\[ dp = P_e - \frac{\sum f P_{f, weak} A_f}{\sum f A_f} \]  
(6.79)

The strong enforcement is applicable when the flow is fully subsonic throughout the boundary.

For all of the three pressure specification methods, if the flow becomes locally supersonic, then the face pressure values \( P_f \) are extrapolated from the interior cell pressure.

---

**Important**

When one of the NRBC model, none of the above specification methods are relevant since face pressure will be obtained from special NRBC procedures.

---

**Important**

If you are specifying a profile rather than a constant value for exit pressure or if you are using radial equilibrium pressure distribution, then you should not use the average pressure specification boundary.

### 6.3.8.4. Other Optional Inputs at Pressure Outlet Boundaries

#### 6.3.8.4.1. Non-Reflecting Boundary Conditions Option

One of the options that may be used at pressure outlets is non-reflecting boundary conditions (NRBC option is used when waves are made to pass through the boundaries while avoiding false reflections. Details of non-reflecting boundary conditions can be found in General Non-Reflecting Boundary Conditions (p. 362) of this chapter.
6.3.8.4.2. Target Mass Flow Rate Option

The simple Bernoulli's equation is used to adjust the pressure at every iteration on a pressure outlet zone in order to meet the desired mass flow rate. The change in pressure, based on Bernoulli's equation is given by the following equation:

\[ dP = 0.5 \rho_{ave} \left( \frac{m^2 - \dot{m}_{req}^2}{\rho_{ave} A} \right)^2 \]  

(6.80)

where \( dP \) is the change in pressure, \( m \) is the current computed mass flow rate at the pressure-outlet boundary, \( \dot{m}_{req} \) is the required mass flow rate, \( \rho_{ave} \) is the computed average density at the pressure-outlet boundary, and \( A \) is the area of the pressure-outlet boundary.

6.3.8.4.3. Limitations

- The target mass flow rate option is not available with multiphase flows or when any of the non-reflecting boundary conditions models are used.
- If the pressure-outlet zone is used in the mixing-plane model, the target mass flow rate option will not be available for that particular zone.
- The pressure outlet will not achieve the target mass flow rate if the flow becomes choked (that is, the Mach number of the fluid in the pressure-outlet zone becomes equal to 1).

6.3.8.4.4. Target Mass Flow Rate Settings

To use the target mass flow rate option

1. Enable Target Mass Flow Rate in the Pressure Outlet dialog box.
2. Specify the Target Mass Flow as either a constant value or hook a UDF to set the target mass flow rate.

The settings for the target mass flow rate option can be accessed from the target-mass-flow-rate-settings text command:

\[ \text{define \rightarrow boundary-conditions \rightarrow target-mass-flow-rate-settings} \]

You will be prompted to

a. Set the under-relaxation factor (the default setting is 0.05).

b. Enable the targeted mass flow rate verbosity (the default is no). If enabled, it prints to the console window the required mass flow rate, computed mass flow rate, mean pressure, the new pressure imposed on the outlet, and the change in pressure in SI units.

3. In the Pressure Outlet dialog box, specify the Upper Limit of Absolute Pressure and Lower Limit of Absolute Pressure. Specifying the range of the pressure limits improves convergence in cases with a large number of outlet boundaries, which have different pressure variations on different boundaries. You can also use the define/boundary-conditions/pressure-outlet text command to specify these limits.
6.3.8.4.5. Solution Strategies When Using the Target Mass Flow Rate Option

If convergence difficulties are encountered or if the solution is not converging at the desired mass flow rate, then try to lower the under-relaxation factor from the default value. Otherwise, you can use the alternate method to converge at the required mass flow rate.

In some cases, you may want to switch off the target mass flow rate option initially, then guess an exit pressure that will bring the solution closer to the target mass flow rate. After the solution stabilizes, you can turn on the target mass flow rate option and iterate to convergence. For many complex flow problems, this strategy is usually very successful.

The use of Full Multigrid Initialization is also very helpful in obtaining a good starting solution and in general will reduce the time required to get a converged solution on a target mass flow rate. For further information on Full Multigrid Initialization, see Full Multigrid (FMG) Initialization (p. 1449).
6.3.8.4.6. Setting Target Mass Flow Rates Using UDFs

For some unsteady problems it is desirable that the target mass flow rate be a function of the physical flow time. This enforcement of boundary condition can be done by attaching a UDF with DEFINE_PROFILE functions to the target mass flow rate field.

**Important**

Note that the mass flow rate profile is a function of time and only one constant value should be applied to all zone faces at a given time.

An example of a simple UDF using a DEFINE_PROFILE that will adjust the mass flow rate can be found in DEFINE_PROFILE in the UDF Manual.

6.3.9. Pressure Far-Field Boundary Conditions

Pressure far-field conditions are used in ANSYS Fluent to model a free-stream condition at infinity, with free-stream Mach number and static conditions being specified. The pressure far-field boundary condition is often called a characteristic boundary condition, since it uses characteristic information (Riemann invariants) to determine the flow variables at the boundaries.

**6.3.9.1. Limitations**

Note the following limitations and restrictions when using pressure far-field boundary conditions:

- This boundary condition is applicable only when the density is calculated using the ideal-gas law (see Density (p. 416)). Using it for other flows is not permitted. To effectively approximate true infinite-extent conditions, you must place the far-field boundary far enough from the object of interest. For example, in lifting airfoil calculations, it is not uncommon for the far-field boundary to be a circle with a radius of 20 chord lengths.

- It is incompatible with the multiphase models (VOF, mixture, and Eulerian) that are available with the pressure-based solver.

- It cannot be applied to flows that employ constant density, the real gas model, and the wet steam model, which are available in the density-based solver.

For an overview of flow boundaries, see Flow Inlet and Exit Boundary Conditions (p. 256).

**6.3.9.2. Inputs at Pressure Far-Field Boundaries**

**6.3.9.2.1. Summary**

You will enter the following information for a pressure far-field boundary:

- static pressure
- Mach number
- temperature
- flow direction
• turbulence parameters (for turbulent calculations)

• radiation parameters (for calculations using the P-1 model, the DTRM, the DO model, or the surface-to-surface model)

• chemical species mass or mole fractions (for species calculations)

• discrete phase boundary conditions (for discrete phase calculations)

All values are entered in the Pressure Far-Field Dialog Box (p. 2138) (Figure 6.26: The Pressure Far-Field Dialog Box (p. 299)), which is opened from the Boundary Conditions task page (as described in Setting Cell Zone and Boundary Conditions (p. 204)).

6.3.9.2.2. Defining Static Pressure, Mach Number, and Static Temperature

To set the static pressure and temperature at the far-field boundary in the Pressure Far-Field dialog box, enter the appropriate values for Gauge Pressure and Mach Number in the Momentum tab. The Mach number can be subsonic, sonic, or supersonic. Set the Temperature in the Thermal tab.

6.3.9.2.3. Defining the Flow Direction

You can define the flow direction at a pressure far-field boundary by setting the components of the direction vector. If your geometry is 2D non-axisymmetric enter appropriate values for X and Y in the Pressure Far-Field dialog box (Figure 6.26: The Pressure Far-Field Dialog Box (p. 299)). If your geometry
is 2D axisymmetric, enter the appropriate values for \textbf{Axial}, \textbf{Radial}, and (if you are modeling axisymmetric swirl) \textbf{Tangential-Component of Flow Direction}.

If your geometry is 3D, you can choose a \textbf{Coordinate System} that is \textbf{Cartesian}, \textbf{Cylindrical}, or \textbf{Local Cylindrical}. In the Cartesian coordinate system, enter the appropriate values for \textbf{X}, \textbf{Y}, and \textbf{Z-Component of Flow Direction}. If the direction cosine data on the boundary is available, then use the cylindrical or local cylindrical coordinate system and specify the \textbf{Axial}, \textbf{Radial}, \textbf{Tangential-Component of Flow Direction}. For \textbf{Cylindrical}, axis parameters need to be specified on the adjacent cell zone of the boundary face. For \textbf{Local Cylindrical Swirl}, specify the \textbf{Axis Origin} and \textbf{Axis Direction}.

\subsection{6.3.9.2.4. Defining Turbulence Parameters}

For turbulent calculations, there are several ways in which you can define the turbulence parameters. Instructions for deciding which method to use and determining appropriate values for these inputs are provided in \textit{Determining Turbulence Parameters} (p. 257). Turbulence modeling is described in \textit{Modeling Turbulence} (p. 695).

\subsection{6.3.9.2.5. Defining Radiation Parameters}

If you are using the P-1 radiation model, the DTRM, the DO model, or the surface-to-surface model, you will set the \textbf{Internal Emissivity} and (optionally) \textbf{External Black Body Temperature Method}. See \textit{Defining Boundary Conditions for Radiation} (p. 798) for details.

\subsection{6.3.9.2.6. Defining Species Transport Parameters}

If you are modeling species transport, you will set the species mass or mole fractions under \textbf{Species Mass Fractions} or \textbf{Species Mole Fractions}. See \textit{Defining Cell Zone and Boundary Conditions for Species} (p. 910) for details.

\subsection{6.3.9.3. Defining Discrete Phase Boundary Conditions}

If you are modeling a discrete phase of particles, you can set the fate of particle trajectories at the pressure far-field boundary. See \textit{Setting Boundary Conditions for the Discrete Phase} (p. 1189) for details.

\subsection{6.3.9.4. Default Settings at Pressure Far-Field Boundaries}

Default settings (in SI) for pressure far-field boundary conditions are as follows:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gauge Pressure</td>
<td>0</td>
</tr>
<tr>
<td>Mach Number</td>
<td>0.6</td>
</tr>
<tr>
<td>Temperature</td>
<td>300</td>
</tr>
<tr>
<td>X-Component of Flow Direction</td>
<td>1</td>
</tr>
<tr>
<td>Y-Component of Flow Direction</td>
<td>0</td>
</tr>
<tr>
<td>Z-Component of Flow Direction</td>
<td>0</td>
</tr>
<tr>
<td>Turbulent Intensity</td>
<td>5%</td>
</tr>
<tr>
<td>Turbulent Viscosity Ratio</td>
<td>10</td>
</tr>
</tbody>
</table>

\subsection{6.3.9.5. Calculation Procedure at Pressure Far-Field Boundaries}

The pressure far-field boundary condition is a non-reflecting boundary condition based on the introduction of Riemann invariants (that is, characteristic variables) for a one-dimensional flow normal to the
boundary. For flow that is subsonic there are two Riemann invariants, corresponding to incoming and outgoing waves:

\[
R_{\infty} = v_{n,\infty} - \frac{2c_{\infty}}{\gamma - 1}
\]

\[
R_i = v_{n,i} + \frac{2c_i}{\gamma - 1}
\]

(6.81)  

(6.82)

where \( v_{n} \) is the velocity magnitude normal to the boundary, \( c \) is the local speed of sound and \( \gamma \) is the ratio of specific heats (ideal gas). The subscript \( \infty \) refers to conditions being applied at infinity (the boundary conditions), and the subscript \( i \) refers to conditions in the interior of the domain (that is, in the cell adjacent to the boundary face). These two invariants can be added and subtracted to give the following two equations:

\[
v_n = \frac{1}{2} (R_i + R_{\infty})
\]

\[
c = \frac{\gamma - 1}{4} (R_i - R_{\infty})
\]

(6.83)  

(6.84)

where \( v_n \) and \( c \) become the values of normal velocity and sound speed applied on the boundary. At a face through which flow exits, the tangential velocity components and entropy are extrapolated from the interior; at an inflow face, these are specified as having free-stream values. Using the values for \( v_{n,\infty} \), \( c \), tangential velocity components, and entropy the values of density, velocity, temperature, and pressure at the boundary face can be calculated.

### 6.3.10. Outflow Boundary Conditions

Outflow boundary conditions in ANSYS Fluent are used to model flow exits where the details of the flow velocity and pressure are not known prior to solving the flow problem. You do not define any conditions at outflow boundaries (unless you are modeling radiative heat transfer, a discrete phase of particles, or split mass flow): ANSYS Fluent extrapolates the required information from the interior. It is important, however, to understand the limitations of this boundary type.

**Important**

Note that outflow boundaries cannot be used in the following cases:

- If a problem includes pressure inlet boundaries; use pressure outlet boundary conditions (see *Pressure Outlet Boundary Conditions (p. 289)*) instead.

- If you are modeling compressible flow.

- If you are modeling unsteady flows with varying density (even if the fluid is incompressible), it is preferable to use a pressure outlet.

In general, an outflow condition may be used in incompressible cases using the Eulerian or Mixture multiphase models. However, if the flow may produce a recirculation at the outlet or if the flow field is not stable and fully developed at the outlet, then a pressure outlet boundary condition is preferred.

For an overview of flow boundaries, see *Flow Inlet and Exit Boundary Conditions (p. 256).*
6.3.10.1. ANSYS Fluent’s Treatment at Outflow Boundaries

The boundary conditions used by ANSYS Fluent at outflow boundaries are as follows:

- A zero diffusion flux for all flow variables.
- An overall mass balance correction.

The zero diffusion flux condition applied at outflow cells means that the conditions of the outflow plane are extrapolated from within the domain and have no impact on the upstream flow. The extrapolation procedure used by ANSYS Fluent updates the outflow velocity and pressure in a manner that is consistent with a fully-developed flow assumption, as noted below, when there is no area change at the outflow boundary.

The zero diffusion flux condition applied by ANSYS Fluent at outflow boundaries is approached physically in fully-developed flows. Fully-developed flows are flows in which the flow velocity profile (and/or profiles of other properties such as temperature) is unchanging in the flow direction.

It is important to note that gradients in the cross-stream direction may exist at an outflow boundary. Only the diffusion fluxes in the direction normal to the exit plane are assumed to be zero.

6.3.10.2. Using Outflow Boundaries

As noted in ANSYS Fluent’s Treatment at Outflow Boundaries (p. 302), the outflow boundary condition is obeyed in fully-developed flows where the diffusion flux for all flow variables in the exit direction are zero. However, you may also define outflow boundaries at physical boundaries where the flow is not fully developed—and you can do so with confidence if the assumption of a zero diffusion flux at the exit is expected to have a small impact on your flow solution. The appropriate placement of an outflow boundary is described by example below.

- Outflow boundaries where normal gradients are negligible: Figure 6.27: Choice of the Outflow Boundary Condition Location (p. 302) shows a simple two-dimensional flow problem and several possible outflow boundary location choices. Location C shows the outflow boundary located upstream of the plenum exit but in a region of the duct where the flow is fully-developed. At this location, the outflow boundary condition is exactly obeyed.

Figure 6.27: Choice of the Outflow Boundary Condition Location
• Ill-posed outflow boundaries: Location B in Figure 6.27: Choice of the Outflow Boundary Condition Location (p. 302) shows the outflow boundary near the reattachment point of the recirculation in the wake of the backward-facing step. This choice of outflow boundary condition is ill-posed as the gradients normal to the exit plane are quite large at this point and can be expected to have a significant impact on the flow field upstream. Because the outflow boundary condition ignores these axial gradients in the flow, location B is a poor choice for an outflow boundary. The exit location should be moved downstream from the reattachment point.

Figure 6.27: Choice of the Outflow Boundary Condition Location (p. 302) shows a second ill-posed outflow boundary at location A. Here, the outflow is located where flow is pulled into the ANSYS Fluent domain through the outflow boundary. In situations like this the ANSYS Fluent calculation typically does not converge and the results of the calculation have no validity. This is because when flow is pulled into the domain through an outflow, the mass flow rate through the domain is “floating” or undefined. In addition, when flow enters the domain through an outflow boundary, the scalar properties of the flow are not defined. For example, the temperature of the flow pulled in through the outflow is not defined. (ANSYS Fluent chooses the temperature using the temperature of the fluid adjacent to the outflow, inside the domain.) Therefore you should view all calculations that involve flow entering the domain through an outflow boundary with skepticism. For such calculations, pressure outlet boundary conditions (see Pressure Outlet Boundary Conditions (p. 289)) are recommended.

---

**Important**

Note that convergence may be affected if there is recirculation through the outflow boundary at any point during the calculation, even if the final solution is not expected to have any flow reentering the domain. This is particularly true of turbulent flow simulations.

---

### 6.3.10.3. Mass Flow Split Boundary Conditions

In ANSYS Fluent, it is possible to use multiple outflow boundaries and specify the fractional flow rate through each boundary. In the Outflow Dialog Box (p. 2129), set the **Flow Rate Weighting** to indicate what portion of the outflow is through the boundary.

*Figure 6.28: The Outflow Dialog Box*

The **Flow Rate Weighting** is a weighting factor:
percentage flow through boundary \[= \frac{\text{Flow Rate Weighting specified on boundary}}{\text{sum of all Flow Rate Weightings}} \] (6.85)

By default, the Flow Rate Weighting for all outflow boundaries is set to 1. If the flow is divided equally among all of your outflow boundaries (or if you have just one outflow boundary), you need not change the settings from the default; ANSYS Fluent will scale the flow rate fractions to obtain equal fractions through all outflow boundaries. Therefore, if you have two outflow boundaries and you want half of the flow to exit through each one, no inputs are required from you. If, however, you want 75% of the flow to exit through one, and 25% through the other, you will need to explicitly specify both Flow Rate Weighting values, that is, 0.75 for one boundary and 0.25 for the other.

**Important**

If you specify a Flow Rate Weighting of 0.75 at the first exit and leave the default Flow Rate Weighting (1.0) at the second exit, then the flow through each boundary will be

\[
\text{Boundary 1} = \frac{0.75}{0.75 + 1.0} = 0.429 \text{ or } 42.9% \\
\text{Boundary 2} = \frac{1.0}{0.75 + 1.0} = 0.571 \text{ or } 57.1%
\]

### 6.3.10.4. Other Inputs at Outflow Boundaries

#### 6.3.10.4.1. Radiation Inputs at Outflow Boundaries

In general, there are no boundary conditions for you to set at an outflow boundary. If, however, you are using the P-1 radiation model, the DTRM, the DO model, or the surface-to-surface model, you will set the Internal Emissivity and (optionally) External Black Body Temperature Method in the Outflow dialog box. These parameters are described in Defining Boundary Conditions for Radiation (p. 798). The default value for Internal Emissivity is 1 and the default value for Black Body Temperature is 300.

#### 6.3.10.4.2. Defining Discrete Phase Boundary Conditions

If you are modeling a discrete phase of particles, you can set the fate of particle trajectories at the outflow boundary. See Setting Boundary Conditions for the Discrete Phase (p. 1189) for details.

### 6.3.11. Outlet Vent Boundary Conditions

Outlet vent boundary conditions are used to model an outlet vent with a specified loss coefficient and ambient (discharge) pressure and temperature.

#### 6.3.11.1. Inputs at Outlet Vent Boundaries

You will enter the following information for an outlet vent boundary:

- static pressure
- backflow conditions
  - total (stagnation) temperature (for energy calculations)
– turbulence parameters (for turbulent calculations)
– chemical species mass or mole fractions (for species calculations)
– mixture fraction and variance (for non-premixed or partially premixed combustion calculations)
– progress variable (for premixed or partially premixed combustion calculations)
– multiphase boundary conditions (for general multiphase calculations)

• radiation parameters (for calculations using the P-1 model, the DTRM, the DO model, or the surface-to-surface model)

• discrete phase boundary conditions (for discrete phase calculations)

• loss coefficient

• open channel flow parameters (for open channel flow calculations using the VOF multiphase model)

All values are entered in the Outlet Vent Dialog Box (p. 2131) (Figure 6.29: The Outlet Vent Dialog Box (p. 306)), which is opened from the Boundary Conditions task page (as described in Setting Cell Zone and Boundary Conditions (p. 204)).

The first 4 items listed above are specified in the same way that they are specified at pressure outlet boundaries. See Inputs at Pressure Outlet Boundaries (p. 289) for details. Specification of the loss coefficient is described here. Open channel boundary condition inputs are described in Modeling Open Channel Flows (p. 1275).
6.3.11.1.1. Specifying the Loss Coefficient

An outlet vent is considered to be infinitely thin, and the pressure drop through the vent is assumed to be proportional to the dynamic head of the fluid, with an empirically determined loss coefficient that you supply. That is, the pressure drop, \( \Delta p \), varies with the normal component of velocity through the vent, \( v \), as follows:

\[
\Delta p = k_L \frac{1}{2} \rho v^2
\]

(6.86)

where \( \rho \) is the fluid density, and \( k_L \) is the nondimensional loss coefficient.

**Important**

\( \Delta p \) is the pressure drop in the direction of the flow; therefore the vent will appear as a resistance even in the case of backflow.

You can define a **constant**, **polynomial**, **piecewise-linear**, or **piecewise-polynomial** function for the Loss Coefficient across the vent. The dialog boxes for defining these functions are the same as those used for defining temperature-dependent properties. See Defining Properties Using Temperature-Dependent Functions (p. 412) for details.
6.3.12. Exhaust Fan Boundary Conditions

Exhaust fan boundary conditions are used to model an external exhaust fan with a specified pressure jump and ambient (discharge) pressure.

6.3.12.1. Inputs at Exhaust Fan Boundaries

You will enter the following information for an exhaust fan boundary:

• static pressure

• backflow conditions
  – total (stagnation) temperature (for energy calculations)
  – turbulence parameters (for turbulent calculations)
  – chemical species mass or mole fractions (for species calculations)
  – mixture fraction and variance (for non-premixed or partially premixed combustion calculations)
  – progress variable (for premixed or partially premixed combustion calculations)
  – multiphase boundary conditions (for general multiphase calculations)
  – user-defined scalar boundary conditions (for user-defined scalar calculations)

• radiation parameters (for calculations using the P-1 model, the DTRM, the DO model, or the surface-to-surface model)

• discrete phase boundary conditions (for discrete phase calculations)

• pressure jump

• open channel flow parameters (for open channel flow calculations using the VOF multiphase model)

All values are entered in the Exhaust Fan Dialog Box (p. 2106) (Figure 6.30: The Exhaust Fan Dialog Box (p. 308)), which is opened from the Boundary Conditions task page (as described in Setting Cell Zone and Boundary Conditions (p. 204)).

The first 4 items listed above are specified in the same way that they are specified at pressure outlet boundaries. See Inputs at Pressure Outlet Boundaries (p. 289) for details. Specification of the pressure jump is described here. Open channel boundary condition inputs are described in Modeling Open Channel Flows (p. 1275).

6.3.12.1.1. Specifying the Pressure Jump

An exhaust fan is considered to be infinitely thin, and the discontinuous pressure rise across it is specified as a function of the local fluid velocity normal to the fan. You can define a constant, polynomial, piecewise-linear, or piecewise-polynomial function for the Pressure Jump across the fan. The dialog boxes for defining these functions are the same as those used for defining temperature-dependent properties. See Defining Properties Using Temperature-Dependent Functions (p. 412) for details.
Important

You must be careful to model the exhaust fan so that a pressure rise occurs for forward flow through the fan. In the case of reversed flow, the fan is treated like an inlet vent with a loss coefficient of unity.

6.3.13. Degassing Boundary Conditions

Degassing boundary conditions are used to model a free surface through which dispersed gas bubbles are allowed to escape, but the continuous phase is not. A typical application is a bubble column in which you want to reduce computational cost by not including the freeboard region in the simulation.

When the degassing boundary condition is specified for an outlet, the continuous liquid phase sees the boundary as a free-slip wall and does not leave the domain. The dispersed gas phase sees the boundary as an outlet. The outlet pressure is not specified. Instead, ANSYS Fluent automatically specifies a mass sink for the dispersed gas phase in the cells adjacent to the degassing outlet. The mass sink is calculated using the flux normal to the boundary at the cell center.

Note

The degassing boundary condition is only available for two-phase liquid-gas flows using the Eulerian multiphase model.
6.3.13.1. Limitations

The following limitations apply to the degassing boundary condition in ANSYS Fluent:

- The degassing boundary condition is only available for liquid-gas two-phase flow using the Eulerian model. The primary phase must be liquid.

- In order for the gas to escape from the degassing boundary, gravity must be switched on in the model.

- The degassing boundary condition is only recommended for modelling situations like bubble columns without the freeboard region.

- When postprocessing on a degassing boundary, there is no normal velocity for either phase since the gas escape is modeled by a mass sink in the neighboring cells.

6.3.13.2. Inputs at Degassing Boundaries

No inputs are necessary for the degassing boundary condition. However, the initial condition for volume fraction must be set appropriately. It is recommended that the gas phase volume fraction be initialized with a non-zero value smaller than the steady-state gas holdup value.

6.3.14. Wall Boundary Conditions

Wall boundary conditions are used to bound fluid and solid regions. In viscous flows, the no-slip boundary condition is enforced at walls by default, but you can specify a tangential velocity component in terms of the translational or rotational motion of the wall boundary, or model a “slip” wall by specifying shear. (You can also model a slip wall with zero shear using the symmetry boundary type, but using a symmetry boundary will apply symmetry conditions for all equations. See Symmetry Boundary Conditions (p. 330) for details.)

The shear stress and heat transfer between the fluid and wall are computed based on the flow details in the local flow field.

6.3.14.1. Inputs at Wall Boundaries

6.3.14.1.1. Summary

You will enter the following information for a wall boundary:

- wall motion conditions (for moving or rotating walls)
- shear conditions (for slip walls, optional)
- wall roughness (for turbulent flows, optional)
- thermal boundary conditions (for heat transfer calculations)
- species boundary conditions (for species calculations)
- chemical reaction boundary conditions (for surface reactions)
- radiation boundary conditions (for calculations using the P-1 model, the DTRM, the DO model, or the surface-to-surface model)
- discrete phase boundary conditions (for discrete phase calculations)
• wall adhesion contact angle (for VOF calculations, optional)

### 6.3.14.2. Wall Motion

Wall boundaries can be either stationary or moving. The stationary boundary condition specifies a fixed wall, whereas the moving boundary condition can be used to specify the translational or rotational velocity of the wall, or the velocity components.

Wall motion conditions are entered in the **Momentum** tab of the Wall Dialog Box (p. 2160) (Figure 6.31: The Wall Dialog Box for a Moving Wall (p. 310)), which is opened from the Boundary Conditions Task Page (p. 2102) (as described in Setting Cell Zone and Boundary Conditions (p. 204)). To view the wall motion conditions, click the **Momentum** tab.

**Figure 6.31: The Wall Dialog Box for a Moving Wall**

6.3.14.2.1. Defining a Stationary Wall

For a stationary wall, choose the **Stationary Wall** option under **Wall Motion**.
6.3.14.2.2. Velocity Conditions for Moving Walls

If you want to include tangential motion of the wall in your calculation, you need to define the translational or rotational velocity, or the velocity components. Select the Moving Wall option under Wall Motion. The Wall dialog box will expand, as shown in Figure 6.31: The Wall Dialog Box for a Moving Wall (p. 310), to show the wall velocity conditions.

Note that you cannot use the moving wall condition to model problems where the wall motion with respect to the adjacent cell zone has a component that is normal to the wall itself. For such problems, consider using a Sliding or Dynamic Mesh approach as discussed in Modeling Flows Using Sliding and Dynamic Meshes (p. 559). ANSYS Fluent will neglect any normal component of wall motion that you specify using the methods below.

- **Specifying Relative or Absolute Velocity**

  If the cell zone adjacent to the wall is moving (for example, if you are using a moving reference frame or a sliding mesh), you can choose to specify velocities relative to the zone motion by enabling the Relative to Adjacent Cell Zone option. If you choose to specify relative velocities, a velocity of zero means that the wall is stationary in the relative frame, and therefore moving at the speed of the adjacent cell zone in the absolute frame. If you choose to specify absolute velocities (by enabling the Absolute option), a velocity of zero means that the wall is stationary in the absolute frame, and therefore moving at the speed of the adjacent cell zone—but in the opposite direction—in the relative reference frame.

  **Important**

  If you are using one or more moving reference frames, sliding meshes, or mixing planes, and you want the wall to be fixed in the moving frame, it is recommended that you specify relative velocities (the default) rather than absolute velocities. Then, if you modify the speed of the adjacent cell zone, you will not need to make any changes to the wall velocities, as you would if you specified absolute velocities.

  Note that if the adjacent cell zone is not moving, the absolute and relative options are equivalent.

- **Translational Wall Motion**

  For problems that include linear translational motion of the wall boundary (for example, a rectangular duct with a moving belt as one wall) you can enable the Translational option and specify the wall's Speed and Direction \((X,Y,Z)\) vector. By default, wall motion is “disabled” by the specification of Translational velocity with a Speed of zero.

  If you need to define non-linear translational motion, you will need to use the Components option, described below.

- **Rotational Wall Motion**

  For problems that include rotational wall motion you can enable the Rotational option and define the rotational Speed about a specified axis. To define the axis, set the Rotation-Axis Direction and Rotation-Axis Origin. This axis is independent of the axis of rotation used by the adjacent cell zone, and independent of any other wall rotation axis. For 3D problems, the axis of rotation is the vector passing through the specified Rotation-Axis Origin and parallel to the vector from \((0,0,0)\) to the \((X,Y,Z)\) point specified under Rotation-Axis Direction. For 2D problems, you will specify only the Rotation-Axis Origin; the axis of rotation is the \(z\)-direction vector passing through the specified
point. For 2D axisymmetric problems, you will not define the axis: the rotation will always be about the \( \chi \) axis, with the origin at (0,0).

Note that the modeling of tangential rotational motion will be correct only if the wall bounds a surface of revolution about the prescribed axis of rotation (for example, a circle or cylinder). Note also that rotational motion can be specified for a wall in a stationary reference frame.

- **Wall Motion Based on Velocity Components**

  For problems that include linear or non-linear translational motion of the wall boundary you can enable the **Components** option and specify the **X-Velocity**, **Y-Velocity**, and **Z-Velocity** of the wall. You can define non-linear translational motion using a profile or a user-defined function for the **X-Velocity**, **Y-Velocity**, and/or **Z-Velocity** of the wall.

- **Wall Motion for Two-Sided Walls**

  As discussed earlier in this section, when you read a mesh with a two-sided wall zone (which forms the interface between fluid/solid regions) into ANSYS Fluent, a “shadow” zone will automatically be created so that each side of the wall is a distinct wall zone. For two-sided walls, it is possible to specify different motions for the wall and shadow zones, whether or not they are coupled. Note, however, that you cannot specify motion for a wall (or shadow) that is adjacent to a solid zone.

### 6.3.14.2.3. Shear Conditions at Walls

Four types of shear conditions are available:

- no-slip
- specified shear
- specularity coefficient
- Marangoni stress

The no-slip condition is the default, and it indicates that the fluid sticks to the wall and moves with the same velocity as the wall, if it is moving. The specified shear and Marangoni stress boundary conditions are useful in modeling situations in which the shear stress (rather than the motion of the fluid) is known. Examples of such situations are applied shear stress, slip wall (zero shear stress), and free surface conditions (zero shear stress or shear stress dependent on surface tension gradient). The specified shear boundary condition allows you to specify the \( x \), \( y \), and \( z \) components of the shear stress as constant values or profiles. The Marangoni stress boundary condition allows you to specify the gradient of the surface tension with respect to the temperature at this surface. The shear stress is calculated based on the surface gradient of the temperature and the specified surface tension gradient. The Marangoni stress option is available only for calculations in which the energy equation is being solved.

The specularity coefficient shear condition is specifically used in multiphase with granular flows. The specularity coefficient is a measure of the fraction of collisions that transfer momentum to the wall and its value ranges between zero and unity. This implementation is based on the Johnson and Jackson [41] (p. 2559) boundary conditions for granular flows.

Shear conditions are entered in the **Momentum** tab of the **Wall Dialog Box** (p. 2160), which is opened from the **Boundary Conditions Task Page** (p. 2102) (as described in Setting Cell Zone and Boundary Conditions (p. 204)).
6.3.14.2.4. No-Slip Walls

You can model a no-slip wall by selecting the No Slip option under Shear Condition. This is the default for all walls in viscous flows.

6.3.14.2.5. Specified Shear

In addition to the no-slip wall that is the default for viscous flows, you can model a slip wall by specifying zero or non-zero shear. For non-zero shear, the shear to be specified is the shear at the wall by the fluid. To specify the shear, select the Specified Shear option under Shear Condition (see Figure 6.32: The Wall Dialog Box for Specified Shear (p. 313)). You can then enter $x$, $y$, and $z$ components of shear under Shear Stress. Wall functions for turbulence are not used with the Specified Shear option.

Figure 6.32: The Wall Dialog Box for Specified Shear

![Wall Dialog Box for Specified Shear](image)

6.3.14.2.6. Specularity Coefficient

For multiphase granular flow, you can specify the specularity coefficient such that when the value is zero, this condition is equivalent to zero shear at the wall, but when the value is near unity, there is a significant amount of lateral momentum transfer. To specify the specularity coefficient, select the Specularity Coefficient option under Shear Condition (see Figure 6.33: The Wall Dialog Box for the Specularity Coefficient (p. 314)) and enter the desired value in the text-entry box under Specularity Coefficient.
ANSYS Fluent can also model shear stresses caused by the variation of surface tension due to temperature. The shear stress applied at the wall is given by

\[ \tau = \frac{d\sigma}{dT} \nabla_s T \]  

(6.87)

where \( d\sigma/dT \) is the surface tension gradient with respect to temperature, and \( \nabla_s T \) is the surface gradient. This shear stress is then applied to the momentum equation.

To model Marangoni stress for the wall, select the Marangoni Stress option under Shear Condition (see Figure 6.34: The Wall Dialog Box for Marangoni Stress (p. 315)). This option is available only for calculations in which the energy equation is being solved. You can then enter the surface tension gradient \( (d\sigma/dT) \) in Equation 6.87 (p. 314) in the Surface Tension Gradient field. Wall functions for turbulence are not used with the Marangoni Stress option.

Fluid flows over rough surfaces are encountered in diverse situations. Examples are, among many others, flows over the surfaces of airplanes, ships, turbomachinery, heat exchangers, and piping systems, and atmospheric boundary layers over terrain of varying roughness. Wall roughness affects drag (resistance) and heat and mass transfer on the walls.

If you are modeling a turbulent wall-bounded flow in which the wall roughness effects are considered to be significant, you can include the wall roughness effects through the law-of-the-wall modified for roughness.

6.3.14.2.9. Law-of-the-Wall Modified for Roughness

Experiments in roughened pipes and channels indicate that the mean velocity distribution near rough walls, when plotted in the usual semi-logarithmic scale, has the same slope \( (1/\kappa) \) but a different intercept (additive constant \( B \) in the log-law). Therefore, the law-of-the-wall for mean velocity modified for roughness has the form

\[
\frac{u_p^*}{\tau_w^*} = \frac{1}{\kappa} \ln \left( \frac{\rho u_p^* y_p^*}{\mu} \right) - \Delta B
\]

where \( u^* = C_{\mu} u^{1/4} \kappa^{1/2} \) and
where \( f' \) is a roughness function that quantifies the shift of the intercept due to roughness effects.

\[ \Delta B = \frac{1}{\kappa} \ln f'_r \]  

(6.89)

\[ \Delta B \] depends, in general, on the type (uniform sand, rivets, threads, ribs, mesh-wire, etc.) and size of the roughness. There is no universal roughness function valid for all types of roughness. For a sand-grain roughness and similar types of uniform roughness elements, however, \( \Delta B \) has been found to be well-correlated with the nondimensional roughness height, \( K_s^+ = \rho K_s u^* / \mu \), where \( K_s \) is the physical roughness height and \( u^* = C_{fL}^{1/4} k^{1/2} \). Analyses of experimental data show that the roughness function is not a single function of \( K_s^+ \), but takes different forms depending on the \( K_s^+ \) value. It has been observed that there are three distinct regimes:

- hydrodynamically smooth \( (K_s^+ \leq 2.25) \)
- transitional \( (2.25 < K_s^+ \leq 90) \)
- fully rough \( (K_s^+ > 90) \)

According to the data, roughness effects are negligible in the hydrodynamically smooth regime, but become increasingly important in the transitional regime, and take full effect in the fully rough regime.

In ANSYS Fluent, the whole roughness regime is subdivided into the three regimes, and the formulas proposed by Cebeci and Bradshaw based on Nikuradse’s data [15] (p. 2557) are adopted to compute \( \Delta B \) for each regime.

For the hydrodynamically smooth regime \( (K_s^+ \leq 2.25) \):

\[ \Delta B = 0 \]  

(6.90)

For the transitional regime \( (2.25 < K_s^+ \leq 90) \):

\[ \Delta B = \frac{1}{\kappa} \ln \left[ \frac{K_s^+ - 2.25}{87.75} + C_s K_s^+ \right] \times \sin \{0.4258 (\ln K_s^+ - 0.811)\} \]  

(6.91)

where \( C_s \) is a roughness constant, and depends on the type of the roughness.

In the fully rough regime \( (K_s^+ > 90) \):

\[ \Delta B = \frac{1}{\kappa} \ln (1 + C_s K_s^+) \]  

(6.92)

In the solver, given the roughness parameters, \( \Delta B (K_s^+) \) is evaluated using the corresponding formula (Equation 6.90 (p. 316), Equation 6.91 (p. 316), or Equation 6.92 (p. 316)). The modified law-of-the-wall in Equation 6.88 (p. 315) is then used to evaluate the shear stress at the wall and other wall functions for the mean temperature and turbulent quantities.

Besides the shift in the law-of-the-wall, an additional modification has been made to account for the displacement caused by the surface roughness. The viscous sublayer is fully established only near hydraulically smooth walls. In the transitional roughness regime, the roughness elements are slightly
thicker than the viscous sublayer and start to disturb it, so that in fully rough flows, the sublayer is destroyed and viscous effects become negligible. The following figure illustrates the equivalent sand-grain roughness using a wall with a layer of closely packed spheres, which have an average roughness height (see for example, Schlichting and Gersten [88] (p. 2561)):

**Figure 6.35: Illustration of Equivalent Sand-Grain Roughness**

It can be assumed that the roughness has a blockage effect, which is about 50% of its height (note that the figure above shows a two-dimensional cut of a three-dimensional arrangement). This leads to the idea to shift the wall physically to 50% of the height of the roughness elements:

\[ y^+ = y^+ + \frac{K_s^+}{2} \]  

(6.93)

which gives about the correct displacement caused by the surface roughness.

This shift is the default treatment for rough walls for all turbulence models based on the \( \omega \)-equation and for the following turbulence models based on the \( \varepsilon \)-equation, when they are used with standard and scalable wall functions. The use of scalable wall functions is recommended:

- Standard, RNG and realizable K-\( \varepsilon \) model
- Reynolds stress models

**Note**

Rough walls cannot be used together with the \( \varepsilon \)-equation and enhanced wall treatment.

**Important**

Prior to ANSYS Fluent 14, the shift described by Equation 6.93 (p. 317) was not applied when using turbulence models based on the \( \varepsilon \)-equation. You can recover the previous code behavior by using the following scheme command:

```
(rpsetvar 'ke-rough-wall-treatment-r14? #f)
(models-changed)
```

### 6.3.14.2.10. Setting the Roughness Parameters

The roughness parameters are in the **Momentum** tab of the Wall Dialog Box (p. 2160) (see Figure 6.34: The Wall Dialog Box for Marangoni Stress (p. 315)), which is opened from the **Boundary Conditions Task Page** (p. 2102) (as described in Setting Cell Zone and Boundary Conditions (p. 204)).

To model the wall roughness effects, you must specify two roughness parameters: the **Roughness Height**, \( K_s \), and the **Roughness Constant**, \( C_s \). The default roughness height (\( K_s \)) is zero, which corres-
ponds to smooth walls. For the roughness to take effect, you must specify a non-zero value for $K_s$. For a uniform sand-grain roughness, the height of the sand-grain can simply be taken for $K_s$. For a non-uniform sand-grain, however, the mean diameter ($D_{50}$) would be a more meaningful roughness height. For other types of roughness, an “equivalent” sand-grain roughness height could be used for $K_s$. The above approaches are only relevant if the height is considered constant per surface. However, if the roughness constant or roughness height is not constant, then you can specify a profile (see Profiles (p. 377)). Similarly, user-defined functions may be used to define a wall roughness height that is not constant. For details on the format of user-defined functions, refer to the UDF Manual.

Choosing a proper roughness constant ($C_s$) is dictated mainly by the type of the given roughness. The default roughness constant ($C_s = 0.5$) was determined so that, when used with $k-\varepsilon$ turbulence models, it reproduces Nikuradse’s resistance data for pipes roughened with tightly-packed, uniform sand-grain roughness. You may need to adjust the roughness constant when the roughness you want to model departs much from uniform sand-grain. For instance, there is some experimental evidence that, for non-uniform sand-grains, ribs, and wire-mesh roughness, a higher value ($C_s = 0.8 \sim 1.0$) is more appropriate. Unfortunately, a clear guideline for choosing $C_s$ for arbitrary types of roughness is not available.

---

**Note**

The rough wall formulation using the shift introduced in Equation 6.93 (p. 317) eliminates all restrictions with respect to mesh resolution near the wall and can therefore be run on arbitrary fine meshes.

**6.3.14.3. Thermal Boundary Conditions at Walls**

When you are solving the energy equation, you need to define thermal boundary conditions at wall boundaries. Five types of thermal conditions are available:

- fixed heat flux
- fixed temperature
- convective heat transfer
- external radiation heat transfer
- combined external radiation and convection heat transfer

If the wall zone is a “two-sided wall” (a wall that forms the interface between two regions, such as the fluid/solid interface for a conjugate heat transfer problem) a subset of these thermal conditions will be available, but you will also be able to choose whether or not the two sides of the wall are “coupled”. See below for details.

The inputs for each type of thermal condition are described below. If the wall has a non-zero thickness, you should also set parameters for calculating thin-wall thermal resistance and heat generation in the wall, as described below.

You can model conduction within boundary walls and internal (that is, two-sided) walls of your model. This type of conduction, called shell conduction, allows you to more conveniently model heat conduction on walls where the wall thickness is small with respect to the overall geometry (for example, finned heat exchangers or sheet metal in automobile underhoods). Meshing these walls with solid cells would
lead to high-aspect-ratio meshes and a significant increase in the total number of cells. See below for details about shell conduction.

Thermal conditions are entered in the Thermal tab of the Wall Dialog Box (p. 2160) (Figure 6.36: The Wall Dialog Box (Thermal Tab) (p. 319)), which is opened from the Boundary Conditions task page (as described in Setting Cell Zone and Boundary Conditions (p. 204)).

Figure 6.36: The Wall Dialog Box (Thermal Tab)

6.3.14.3.1. Heat Flux Boundary Conditions

For a fixed heat flux condition, choose the Heat Flux option under Thermal Conditions. You will then need to set the appropriate value for the heat flux at the wall surface in the Heat Flux field. You can define an adiabatic wall by setting a zero heat flux condition. This is the default condition for all walls.

6.3.14.3.2. Temperature Boundary Conditions

To select the fixed temperature condition, choose the Temperature option under Thermal Conditions in the Wall dialog box. You will need to specify the temperature at the wall surface (Temperature). The heat transfer to the wall is computed using Equation 6.95 (p. 328) or Equation 6.96 (p. 328).

6.3.14.3.3. Convective Heat Transfer Boundary Conditions

For a convective heat transfer wall boundary, select Convection under Thermal Conditions. Your inputs of Heat Transfer Coefficient and Free Stream Temperature will allow ANSYS Fluent to compute the heat transfer to the wall using Equation 6.99 (p. 329).
6.3.14.3.4. External Radiation Boundary Conditions

If radiation heat transfer from the exterior of your model is of interest, you can enable the Radiation option in the Wall dialog box and set the External Emissivity and External Radiation Temperature.

6.3.14.3.5. Combined Convection and External Radiation Boundary Conditions

You can choose a thermal condition that combines the convection and radiation boundary conditions by selecting the Mixed option. With this thermal condition, you will need to set the Heat Transfer Coefficient, Free Stream Temperature, External Emissivity, and External Radiation Temperature.

6.3.14.3.6. Augmented Heat Transfer

When modeling the heat transfer of applications that have perturbed flow and/or disturbed boundary layers, it can be necessary to augment the calculation of the diffusive heat flux with a convective augmentation factor. Such applications include the modeling of underhood and underbody heat loads, as well as transient heat transfer in fully warmed-up exhaust systems.

The convective augmentation factor represents the ratio of the measured Nusselt number to the Nusselt number of an ideal flow. You can define it by using the following text command:

```
define → boundary-conditions → wall
```

You will be prompted to define the Convective Augmentation Factor as either a profile or a single value. Note that a value of 1 (the default value) represents no augmentation of the diffusive heat flux, whereas values greater than 1 initiate augmentation. For further details, see the equation for $q_{id}$ in `DEFINE_HEAT_FLUX` of the UDF Manual.

6.3.14.3.7. Thin-Wall Thermal Resistance Parameters

By default, a wall will have a thickness of zero. You can, however, in conjunction with any of the thermal conditions, model a thin layer of material on the wall. For example, you can model the effect of a piece of sheet metal between two fluid zones, a coating on a solid zone, or contact resistance between two solid regions. ANSYS Fluent will solve a 1D steady heat conduction equation to compute the thermal resistance offered by the wall and the heat generation in the wall.

To include these effects in the heat transfer calculation you will need to specify the type of material, the thickness of the wall, and the heat generation rate in the wall. Select the material type in the Material Name drop-down list, and specify the thickness in the Wall Thickness field. If you want to check or modify the properties of the selected material, you can click Edit... to open the Edit Material dialog box; this dialog box contains just the properties of the selected material, not the full contents of the standard Create/Edit Materials dialog box.

When you specify a thickness, the wall is then treated as a coupled wall, where the surface that is adjacent to the fluid / solid cells is referred to as the “wall surface”. See Figure 6.37: A Thin Wall (p. 321).
The thermal resistance of the wall is $\frac{\Delta x}{k}$, where $k$ is the conductivity of the wall material and $\Delta x$ is the wall thickness. The thermal wall boundary condition you set will be specified on the surface that is separated from the fluid / solid cells by the wall thickness. The temperature specified at this side of the wall is $T_b$.

**Important**

Note that for thin walls, you can only specify a constant thermal conductivity. If you want to use a non-constant thermal conductivity for a wall with non-zero thickness, you should use the shell conduction model (see Shell Conduction (p. 323) for details).

Specify the heat generation rate inside the wall in the **Heat Generation Rate** field. This option is useful if, for example, you are modeling printed circuit boards where you know the electrical power dissipated in the circuits.

When postprocessing a wall that has a thickness but does not have shell conduction enabled, the **Temperature...** category provides three options: the temperature of the adjacent fluid / solid cells are stored as **Static Temperature**; the temperature of the wall surface itself is stored as **Wall Temperature**; and the temperature of the surface that is separated from the fluid / solid cells by the wall thickness is...
stored as **Wall Temperature (Thin)**. If a more detailed analysis of the solid zone and surfaces is required, then you should consider creating layers of solid cells in your meshing application.

### 6.3.14.3.8. Thermal Conditions for Two-Sided Walls

If the wall zone has a fluid or solid region on each side, it is called a “two-sided wall”. When you read a mesh with this type of wall zone into ANSYS Fluent, a “shadow” zone will automatically be created so that each side of the wall is a distinct wall zone. In the **Wall** dialog box, the shadow zone's name will be shown in the **Shadow Face Zone** field. You can choose to specify different thermal conditions on each zone, or to couple the two zones:

- **To couple the two sides of the wall**, select the **Coupled** option under **Thermal Conditions**. (This option will appear in the **Wall** dialog box only when the wall is a two-sided wall.) No additional thermal boundary conditions are required, because the solver will calculate heat transfer directly from the solution in the adjacent cells. You can, however, specify the material type, wall thickness, and heat generation rate for thin-wall thermal resistance calculations, as described above. Note that the resistance parameters you set for one side of the wall will automatically be assigned to its shadow wall zone. Specifying the heat generation rate inside the wall is useful if, for example, you are modeling printed circuit boards where you know the electrical power dissipated in the circuits but not the heat flux or wall temperature.

- **To uncouple the two sides of the wall** and specify different thermal conditions on each one, choose **Temperature** or **Heat Flux** as the thermal condition type (**Convection** and **Radiation** are not applicable for two-sided walls); note that this uncoupling will not be effective if you have enabled shell conduction for the wall. The relationship between the wall and its shadow will be retained, so that you can couple them again at a later time, if desired. You will need to set the relevant parameters for the selected thermal condition, as described above. The two uncoupled walls can have different thicknesses, and are effectively insulated from one another. If you specify a non-zero wall thickness for the uncoupled walls, the thermal boundary conditions you set will be specified for each thin wall on the surface that is separated from the fluid / solid cells by the wall thickness, as shown in Figure 6.38: Uncoupled Thin Walls (p. 323), where $T_{b1}$ is the **Temperature** (or $q_{b1}$ is the **Heat Flux**) specified on one wall and $T_{b2}$ is the **Temperature** (or $q_{b2}$ is the **Heat Flux**) specified on the other wall. $k_{w1}$ and $k_{w2}$ are the thermal conductivities of the uncoupled thin walls. Note that the gap between the walls in Figure 6.38: Uncoupled Thin Walls (p. 323) is not part of the model; it is included in the figure only to show where the thermal boundary condition for each uncoupled wall is applied.
6.3.14.3.9. Shell Conduction

To enable shell conduction for a wall, enable the Shell Conduction option in the Wall boundary condition dialog box. You can then click the Define... button to open the Shell Conduction Model Settings dialog box, where you can use to define the properties of the single or multiple layers of the shell. Note that you must specify a non-zero wall thickness for every layer of the shell. When shell conduction is enabled, ANSYS Fluent will compute heat conduction for the wall not only in the normal direction (which is always computed when the energy equation is solved), but also in the planar directions. The Shell Conduction option will appear in the Wall dialog box for all walls when solution of the energy equation is active. For information about how the thermal conditions are applied on a wall with shell conduction enabled, managing multiple shells, and postprocessing shell conduction walls, see Shell Conduction Considerations (p. 770).

ANSYS Fluent cases with shell conduction can be read in serial or parallel. Either a partitioned or an unpartitioned case file can be read in parallel (see Mesh Partitioning and Load Balancing (p. 1852) for more information on partitioning). After reading a case file in parallel, shell zones can be created on any wall.

To convert every wall with a finite thickness into a shell with a single action, the TUI command define/boundary-conditions/modify-zones/create-all-shell-threads can be used; each converted shell will have a single layer with the same thickness as the original thin wall (any pre-existing shells will not be modified). To disable shell conduction in every wall with a single action, the
Cell Zone and Boundary Conditions

TUI command `define/boundary-conditions/modify-zones/delete-all-shells` can be used. These capabilities are available in both serial and parallel mode.

---

**Important**

Note that the shell conduction model has several limitations:

- It cannot be applied on non-conformal interfaces.
- It cannot be applied on moving wall zones.
- It cannot be used with FMG initialization.
- Shell conduction is not available when the wall is set up to receive thermal data via system coupling.
- It is available only in 3D.
- It is available only when the pressure-based solver is used.
- Shells cannot be split or merged. If you need to split or merge a shell, disable the Shell Conduction option for the wall, perform the split or merge operation, and then enable Shell Conduction for the new wall zones.
- The shell conduction model cannot be used on a wall zone that has been adapted. If you want to perform adaption elsewhere in the computational domain, be sure to use the mask register described in Manipulating Adaption Registers (p. 1564).
- Fluxes at the ends of a shell are not included in the heat balance reports. These fluxes are accounted for correctly in the ANSYS Fluent solution, but not in the flux report itself.
- The junction of a wall with shell conduction enabled and a non-conformal coupled wall is not supported. Such a junction will not be thermally connected, that is, there will be no heat transfer between the shell and the mesh interface wall.
- The use of the shell conduction model with the node-based gradient method may yield nonphysical results.

---

### 6.3.14.3.10. Heat Transfer Boundary Conditions Through System Coupling

System coupling allows the input and output of thermal data from ANSYS Fluent. When Fluent is coupled with another system in Workbench using System Coupling, you can select the via System Coupling option on the desired wall boundaries to receive thermal data through System Coupling service. Note that this option does not need to be selected to provide thermal data from Fluent.

For more details about setting up a simulation with system coupling, see the Fluent in Workbench User's Guide and the System Coupling User's Guide.

When thermal data is transferred into Fluent via System Coupling, the following variables are available:

- temperature
- heat flow (heat rate)
When thermal data is transferred out of Fluent via System Coupling, the following variables are available:

- temperature
- heat flow (heat rate)
- heat transfer coefficient (also known as “convection coefficient”)
- near wall temperature (also known as “bulk temperature” or “ambient temperature”)

For each data transfer, you specify the type of data transfer (the variables transferred) during the System Coupling setup.

As part of standard heat transfer boundary condition settings in ANSYS Fluent, you can also specify the type of material, the thickness of the wall, and the heat generation rate in the wall. Select the material type in the **Material Name** drop-down list; if you want to check or modify the properties of the selected material, you can click **Edit...** to open the **Edit Material** dialog box (this dialog box contains just the properties of the selected material, and not the full contents of the standard **Create/Edit Materials** dialog box). You can specify the thickness in the **Wall Thickness** number-entry box and the heat generation rate in the **Heat Generation Rate** number-entry box.

**Note**

A boundary will behave in the same way as an adiabatic boundary if the **via System Coupling** option is enabled on this boundary, and ANSYS Fluent is not receiving data from the coupling data transfer. Fluent is not receiving coupling data if it is either not involved with a System Coupling simulation, or if the coupling is a one-way transfer with the Fluent analysis only providing data to the second solver.

### 6.3.14.4. Species Boundary Conditions for Walls

By default, a zero-gradient condition for all species is assumed at walls (except for species that participate in surface reactions), but it is also possible to specify species mass fractions at walls. That is, Dirichlet boundary conditions such as those that are specified at inlets can be used at walls as well.

If you want to retain the default zero-gradient condition for a species, no inputs are required. If you want to specify the mass fraction for a species at the wall, the steps are as follows:

1. Click the **Species** tab in the **Wall Dialog Box** (p. 2160) to view the species boundary conditions for the wall (see **Figure 6.39: The Wall Dialog Box for Species Boundary Condition Input** (p. 326)).

2. Under **Species Boundary Condition**, select **Specified Mass Fraction** (rather than **Zero Diffusive Flux**) in the drop-down list to the right of the species name. The dialog box will expand to include a field for **Species Mass Fractions**.
3. Under **Species Mass Fractions**, specify the mass fraction for the species.

The boundary condition type for each species is specified separately, so you can choose to use different methods for different species.

If you are modeling species transport with reactions, you can, alternatively, enable a reaction mechanism at a wall by turning on the **Reaction** option and selecting an available mechanism from the **Reaction Mechanisms** drop-down list. See **Defining Zone-Based Reaction Mechanisms (p. 904)** for more information about defining reaction mechanisms.

You can also model unresolved surface washcoats, which greatly increase the catalytic surface area, by specifying the **Surface Area Washcoat Factor**. The surface washcoat increases the area available for surface reaction.

### 6.3.14.4.1. Reaction Boundary Conditions for Walls

If you have enabled the modeling of wall surface reactions in the **Species Model Dialog Box (p. 1943)**, you can indicate whether or not surface reactions should be activated for the wall. In the **Species** tab of the **Wall** dialog box (Figure 6.39: The Wall Dialog Box for Species Boundary Condition Input (p. 326)), turn the **Surface Reactions** option on or off.

Note that a zero-gradient condition is assumed at the wall for species that do not participate in any surface reactions.
6.3.14.5. Radiation Boundary Conditions for Walls

If you are using the gray P-1 radiation model, the DTRM, the gray DO model, or the surface-to-surface model, you will need to set the emissivity of the wall (Internal Emissivity) in the Thermal tab of the Wall dialog box. If you are using the Rosseland model you do not need to set the emissivity, because ANSYS Fluent assumes the emissivity is 1.

For the non-gray P–1 and the non-gray DO model, specify a constant Internal Emissivity for each wavelength band in the Radiation tab of the Wall dialog box (the default value in each band is 1). Alternatively, you can specify the internal emissivity using a boundary condition parameter (see Creating a New Parameter (p. 209)). If you are using the non-gray DO model, you will also need to define the wall as opaque or semi-transparent in the Radiation tab. See Defining Boundary Conditions for Radiation (p. 798) for details.

6.3.14.6. Discrete Phase Model (DPM) Boundary Conditions for Walls

If you are modeling a discrete phase of particles, you can set the fate of particle trajectories at the wall in the DPM section of the Wall dialog box. See Setting Boundary Conditions for the Discrete Phase (p. 1189) for details.

6.3.14.6.1. Wall Adhesion Contact Angle for VOF Model

If you are using the VOF model and you are modeling wall adhesion, you can specify the contact angle for each pair of phases at the wall in the Momentum tab of the Wall dialog box. See Steps for Setting Boundary Conditions (p. 1269) for details.

6.3.14.7. User-Defined Scalar (UDS) Boundary Conditions for Walls

If you have defined UDS transport equations in your model, you can specify boundary conditions for each equation in the UDS section of the Wall dialog box. See Setting Up UDS Equations in ANSYS Fluent (p. 507) for details.

6.3.14.8. Wall Film Boundary Conditions for Walls

If you are using the Eulerian Wall Film model (see Modeling Eulerian Wall Films (p. 1397) for details), you can set boundary conditions for liquid films at the wall in the Wall Film tab of the Wall dialog box. This tab is available only if you have enabled the Eulerian Wall Film model in the Models Task Page (p. 1896).

To define a film wall condition for any wall, select the Eulerian Film Wall option. Then, you can enter film boundary condition values for the Film Mass Flux, and X-Momentum Flux, Y-Momentum Flux, and Z-Momentum Flux. Alternatively, you can set initial film conditions for the Film Height and the X-Velocity, Y-Velocity, and Z-Velocity components. You can also select the Flow Momentum Coupling option, that allows the liquid film and the gas flow to share the same velocity at the interface of the liquid-gas interface using a two-way coupling. When this option is not selected, the coupling between the liquid film and the gas flow is only one-way, namely, while the gas flow impacts the film flow, the film flow does not impact the bulk of the gas flow.

6.3.14.9. Default Settings at Wall Boundaries

The default thermal boundary condition is a fixed heat flux of zero. Walls are, by default, not moving.
6.3.14.10. Shear-Stress Calculation Procedure at Wall Boundaries

For no-slip wall conditions, ANSYS Fluent uses the properties of the flow adjacent to the wall/fluid boundary to predict the shear stress on the fluid at the wall. In laminar flows this calculation simply depends on the velocity gradient at the wall, while in turbulent flows one of the approaches described in Near-Wall Treatments for Wall-Bounded Turbulent Flows in the Theory Guide is used.

For specified-shear walls, ANSYS Fluent will compute the tangential velocity at the boundary.

If you are modeling inviscid flow with ANSYS Fluent, all walls use a slip condition, so they are frictionless and exert no shear stress on the adjacent fluid.

6.3.14.10.1. Shear-Stress Calculation in Laminar Flow

In a laminar flow, the wall shear stress is defined by the normal velocity gradient at the wall as

\[ \tau_w = \mu \frac{\partial v}{\partial n} \]  

(6.94)

When there is a steep velocity gradient at the wall, you must be sure that the mesh is sufficiently fine to accurately resolve the boundary layer. Guidelines for the appropriate placement of the near-wall node in laminar flows are provided in Mesh Element Distribution (p. 131).

6.3.14.10.2. Shear-Stress Calculation in Turbulent Flows

Wall treatments for turbulent flows are described in Near-Wall Treatments for Wall-Bounded Turbulent Flows in the Theory Guide.

6.3.14.11. Heat Transfer Calculations at Wall Boundaries

6.3.14.11.1. Temperature Boundary Conditions

When a fixed temperature condition is applied at the wall, the heat flux to the wall from a fluid cell is computed as

\[ q = h_f (T_w - T_f) + q_{rad} \]  

(6.95)

where

- \( h_f \) = fluid-side local heat transfer coefficient
- \( T_w \) = wall surface temperature
- \( T_f \) = local fluid temperature
- \( q_{rad} \) = radiative heat flux

Note that the fluid-side heat transfer coefficient is computed based on the local flow-field conditions (for example, turbulence level, temperature, and velocity profiles), as described by Equation 6.102 (p. 330).

Heat transfer to the wall boundary from a solid cell is computed as

\[ q = \frac{k_w}{\Delta n} (T_w - T_s) + q_{rad} \]  

(6.96)

where

- \( k_w \) = thermal conductivity of the wall
- \( \Delta n \) = thickness of the wall
- \( T_w \) = wall surface temperature
- \( T_s \) = surface temperature of the solid cell
- \( q_{rad} \) = radiative heat flux
\[ k_s = \text{thermal conductivity of the solid} \]
\[ T_s = \text{local solid temperature} \]
\[ \Delta n = \text{distance between wall surface and the solid cell center} \]

**6.3.14.11.2. Heat Flux Boundary Conditions**

When you define a heat flux boundary condition at a wall, you specify the heat flux at the wall surface. ANSYS Fluent uses Equation 6.95 (p. 328) and your input of heat flux to determine the wall surface temperature adjacent to a fluid cell as

\[ T_w = \frac{q - q_{rad}}{h_f} + T_f \]  
(6.97)

where, as noted above, the fluid-side heat transfer coefficient is computed based on the local flow-field conditions. When the wall borders a solid region, the wall surface temperature is computed as

\[ T_w = \left( \frac{q - q_{rad}}{k_s} \right) \Delta n + T_s \]  
(6.98)

**6.3.14.11.3. Convective Heat Transfer Boundary Conditions**

When you specify a convective heat transfer coefficient boundary condition at a wall, ANSYS Fluent uses your inputs of the external heat transfer coefficient and external heat sink temperature to compute the heat flux to the wall as

\[ q = h_f (T_w - T_f) + q_{rad} \]
\[ = h_{ext} (T_{ext} - T_w) \]  
(6.99)

where

\[ h_{ext} = \text{external heat transfer coefficient defined by you} \]
\[ T_{ext} = \text{external heat-sink temperature defined by you} \]
\[ q_{rad} = \text{radiative heat flux} \]

Equation 6.99 (p. 329) assumes a wall of zero thickness.

**6.3.14.11.4. External Radiation Boundary Conditions**

When the external radiation boundary condition is used in ANSYS Fluent, the heat flux to the wall is computed as

\[ q = h_f (T_w - T_f) + q_{rad} \]
\[ = \varepsilon_{ext} \sigma (T_w^4 - T_{\infty}^4) \]  
(6.100)

where

\[ \varepsilon_{ext} = \text{emissivity of the external wall surface defined by you} \]
\[ \sigma = \text{Stefan-Boltzmann constant} \]
\[ T_w = \text{surface temperature of the wall} \]
\[ T_{\infty} = \text{temperature of the radiation source or sink on the exterior of the domain, defined by you} \]
\[ q_{\text{rad}} = \text{radiative heat flux to the wall from within the domain} \]

Equation 6.100 (p. 329) assumes a wall of zero thickness.

**6.3.14.11.5. Combined External Convection and Radiation Boundary Conditions**

When you choose the combined external heat transfer condition, the heat flux to the wall is computed as

\[
q = h_f (T_w - T_f) + q_{\text{rad}} = h_{\text{ext}} (T_{\text{ext}} - T_w) + \varepsilon_{\text{ext}} \sigma (T_{\infty}^4 - T_w^4)
\]  

(6.101)

where the variables are as defined above. Equation 6.101 (p. 330) assumes a wall of zero thickness.

**6.3.14.11.6. Calculation of the Fluid-Side Heat Transfer Coefficient**

In laminar flows, the fluid side heat transfer at walls is computed using Fourier’s law applied at the walls. ANSYS Fluent uses its discrete form:

\[
q = k_f \left( \frac{\partial T}{\partial n} \right)_{\text{wall}}
\]  

(6.102)

where \( n \) is the local coordinate normal to the wall.

**6.3.15. Symmetry Boundary Conditions**

Symmetry boundary conditions are used when the physical geometry of interest, and the expected pattern of the flow/thermal solution, have mirror symmetry. They can also be used to model zero-shear slip walls in viscous flows. This section describes the treatment of the flow at symmetry planes and provides examples of the use of symmetry. You do not define any boundary conditions at symmetry boundaries, but you must take care to correctly define your symmetry boundary locations.

**Important**

At the centerline of an axisymmetric geometry, you should use the axis boundary type rather than the symmetry boundary type, as illustrated in Figure 6.47: Use of an Axis Boundary as the Centerline in an Axisymmetric Geometry (p. 335). See Axis Boundary Conditions (p. 335) for details.
6.3.15.1. Examples of Symmetry Boundaries

Symmetry boundaries are used to reduce the extent of your computational model to a symmetric subsection of the overall physical system. Figure 6.40: Use of Symmetry to Model One Quarter of a 3D Duct (p. 331) and Figure 6.41: Use of Symmetry to Model One Quarter of a Circular Cross-Section (p. 331) illustrate two examples of symmetry boundary conditions used in this way.

Figure 6.40: Use of Symmetry to Model One Quarter of a 3D Duct

Figure 6.41: Use of Symmetry to Model One Quarter of a Circular Cross-Section

Figure 6.42: Inappropriate Use of Symmetry (p. 332) illustrates two problems in which a symmetry plane would be inappropriate. In both examples, the problem geometry is symmetric but the flow itself does not obey the symmetry boundary conditions. In the first example, buoyancy creates an asymmetric flow. In the second, swirl in the flow creates a flow normal to the would-be symmetry plane. Note that this second example should be handled using rotationally periodic boundaries (as illustrated in Figure 6.43: Use of Periodic Boundaries to Define Swirling Flow in a Cylindrical Vessel (p. 333)).
6.3.15.2. Calculation Procedure at Symmetry Boundaries

ANSYS Fluent assumes a zero flux of all quantities across a symmetry boundary. There is no convective flux across a symmetry plane: the normal velocity component at the symmetry plane is therefore zero. There is no diffusion flux across a symmetry plane: the normal gradients of all flow variables are therefore zero at the symmetry plane. The symmetry boundary condition can therefore be summarized as follows:

- zero normal velocity at a symmetry plane
- zero normal gradients of all variables at a symmetry plane

As stated above, these conditions determine a zero flux across the symmetry plane, which is required by the definition of symmetry. Since the shear stress is zero at a symmetry boundary, it can also be interpreted as a “slip” wall when used in viscous flow calculations.

6.3.16. Periodic Boundary Conditions

Periodic boundary conditions are used when the physical geometry of interest and the expected pattern of the flow/thermal solution have a periodically repeating nature. Two types of periodic conditions are available in ANSYS Fluent. The first type does not allow a pressure drop across the periodic planes. (Note to FLUENT 4 users: This type of periodic boundary is referred to as a “cyclic” boundary in FLUENT 4.) The second type allows a pressure drop to occur across translationally periodic boundaries, enabling you to model “fully-developed” periodic flow. (In FLUENT 4 this is a “periodic” boundary.)

This section discusses the no-pressure-drop periodic boundary condition. A complete description of the fully-developed periodic flow modeling capability is provided in Periodic Flows (p. 514).
6.3.16.1. Examples of Periodic Boundaries

Periodic boundary conditions are used when the flows across two opposite planes in your computational model are identical. Figure 6.43: Use of Periodic Boundaries to Define Swirling Flow in a Cylindrical Vessel (p. 333) illustrates a typical application of periodic boundary conditions. In this example the flow entering the computational model through one periodic plane is identical to the flow exiting the domain through the opposite periodic plane. Periodic planes are always used in pairs as illustrated in this example.

Figure 6.43: Use of Periodic Boundaries to Define Swirling Flow in a Cylindrical Vessel

6.3.16.2. Inputs for Periodic Boundaries

For a periodic boundary without any pressure drop, there is only one input you need to consider: whether the geometry is rotationally or translationally periodic. (Additional inputs are required for a periodic flow with a periodic pressure drop. See Periodic Flows (p. 514).)

Rotationally periodic boundaries are boundaries that form an included angle about the centerline of a rotationally symmetric geometry. Figure 6.43: Use of Periodic Boundaries to Define Swirling Flow in a Cylindrical Vessel (p. 333) illustrates rotational periodicity. Translationally periodic boundaries are boundaries that form periodic planes in a rectilinear geometry. Figure 6.44: Example of Translational Periodicity - Physical Domain (p. 333) illustrates translationally periodic boundaries.

Figure 6.44: Example of Translational Periodicity - Physical Domain
Figure 6.45: Example of Translational Periodicity - Modeled Domain

You will specify translational or rotational periodicity for a periodic boundary in the Periodic Dialog Box (p. 2135) (Figure 6.46: The Periodic Dialog Box (p. 334)), which is opened from the Boundary Conditions task page (as described in Setting Cell Zone and Boundary Conditions (p. 204)).

Figure 6.46: The Periodic Dialog Box

Note that there will be an additional item in the Periodic dialog box for the density-based solver, which allows you to specify the periodic pressure jump. See Periodic Flows (p. 514) for details.

If the domain is rotationally periodic, select Rotational as the Periodic Type; if it is translationally periodic, select Translational. For rotationally periodic domains, the solver will automatically compute the angle through which the periodic zone is rotated. The axis used for this rotation is the axis of rotation specified for the adjacent cell zone.

Note that there is no need for the adjacent cell zone to be moving for you to use a rotationally periodic boundary. You could, for example, model pipe flow in 3D using a stationary reference frame with a pie-slice of the pipe; the sides of the slice would require rotational periodicity.

You can use the Mesh/Check menu item (see Checking the Mesh (p. 162)) to compute and display the minimum, maximum, and average rotational angles of all faces on periodic boundaries. If the difference between the minimum, maximum, and average values is not negligible, then there is a problem with the mesh: the mesh geometry is not periodic about the specified axis.
6.3.16.3. **Default Settings at Periodic Boundaries**

By default, all periodic boundaries are translational.

6.3.16.4. **Calculation Procedure at Periodic Boundaries**

ANSYS Fluent treats the flow at a periodic boundary as though the opposing periodic plane is a direct neighbor to the cells adjacent to the first periodic boundary. Therefore, when calculating the flow through the periodic boundary adjacent to a fluid cell, the flow conditions at the fluid cell adjacent to the opposite periodic plane are used.

6.3.17. **Axis Boundary Conditions**

The axis boundary type must be used as the centerline of an axisymmetric geometry (see Figure 6.47: Use of an Axis Boundary as the Centerline in an Axisymmetric Geometry (p. 335)). It can also be used for the centerline of a cylindrical-polar quadrilateral or hexahedral mesh (for example, a mesh created for a structured-mesh code such as FLUENT 4). You do not need to define any boundary conditions at axis boundaries.

**Important**

When creating 2D axisymmetric geometry, the axis boundary must lie on the y=0 line.

6.3.17.1. **Calculation Procedure at Axis Boundaries**

To determine the appropriate physical value for a particular variable at a point on the axis, ANSYS Fluent uses the cell value in the adjacent cell.

6.3.18. **Fan Boundary Conditions**

The fan model is a lumped parameter model that can be used to determine the impact of a fan with known characteristics upon some larger flow field. The fan boundary type allows you to input an empirical fan curve that governs the relationship between head (pressure rise) and flow rate (velocity) across a fan element. You can also specify radial and tangential components of the fan swirl velocity. The fan model does not provide an accurate description of the detailed flow through the fan blades. Instead, it predicts the amount of flow through the fan. Fans may be used in conjunction with other...
flow sources, or as the sole source of flow in a simulation. In the latter case, the system flow rate is
determined by the balance between losses in the system and the fan curve.

ANSYS Fluent also provides a connection for a special user-defined fan model that updates the pressure
jump function during the calculation. This feature is described in User-Defined Fan Model (p. 370).

6.3.18.1. Fan Equations

6.3.18.1.1. Modeling the Pressure Rise Across the Fan

A fan is considered to be infinitely thin, and the discontinuous pressure rise across it is specified as a
function of the velocity through the fan. The relationship may be a constant, a polynomial, piecewise-linear,
or piecewise-polynomial function, or a user-defined function.

In the case of a polynomial, the relationship is of the form

\[ \Delta p = \sum_{n=1}^{N} f_n v^{n-1} \]  

(6.103)

where \( \Delta p \) is the pressure jump, \( f_n \) are the pressure-jump polynomial coefficients, and \( v \) is the magnitude
of the local fluid velocity normal to the fan.

**Important**

The velocity \( v \) can be either positive or negative. You must be careful to model the fan so
that a pressure rise occurs for forward flow through the fan.

You can, optionally, use the mass-averaged velocity normal to the fan to determine a single pressure-jump value for all faces in the fan zone.

6.3.18.1.2. Modeling the Fan Swirl Velocity

For three-dimensional problems, the values of the convected tangential and radial velocity fields can
be imposed on the fan surface to generate swirl. These velocities can be specified as functions of the
radial distance from the fan center. The relationships may be constant or polynomial functions, or user-defined functions.

**Important**

You must use SI units for all fan swirl velocity inputs.

For the case of polynomial functions, the tangential and radial velocity components can be specified
by the following equations:

\[ U_\theta = \sum_{n=-1}^{N} f_n r^n; \quad -1 \leq N \leq 6 \]  

(6.104)

\[ U_r = \sum_{n=-1}^{N} g_n r^n; \quad -1 \leq N \leq 6 \]  

(6.105)
where \( U_{\theta} \) and \( U_r \) are, respectively, the tangential and radial velocities on the fan surface in m/s, \( f_n \) and \( g_n \) are the tangential and radial velocity polynomial coefficients, and \( r \) is the distance to the fan center.

**6.3.18.2. User Inputs for Fans**

Once the fan zone has been identified (in the **Boundary Conditions** task page), you will set all modeling inputs for the fan in the Fan Dialog Box (p. 2110) (Figure 6.48: The Fan Dialog Box (p. 337)), which is opened from the **Boundary Conditions Task Page** (p. 2102) (as described in **Setting Cell Zone and Boundary Conditions** (p. 204)).

**Figure 6.48: The Fan Dialog Box**

Inputs for a fan are as follows:

1. Identify the fan zone.
2. Define the pressure jump across the fan.
3. Define the discrete phase boundary condition for the fan (for discrete phase calculations).
4. Define the swirl velocity, if desired (3D only).

**6.3.18.2.1. Identifying the Fan Zone**

Since the fan is considered to be infinitely thin, it must be modeled as the interface between cells, rather than a cell zone. Therefore the fan zone is a type of internal face zone (where the faces are line segments in 2D or triangles/quadrilaterals in 3D). If, when you read your mesh into ANSYS Fluent, the fan zone is identified as an **interior** zone, use the **Boundary Conditions** task page (see **Boundary Conditions Task Page** (p. 2102)) (as described in **Changing Cell and Boundary Zone Types** (p. 203)) to change the appropriate **interior** zone to a **fan** zone.
Once the interior zone has been changed to a fan zone, you can open the Fan dialog box and specify the pressure jump and, optionally, the swirl velocity.

6.3.18.2.2. Defining the Pressure Jump

To define the pressure jump, you will specify a polynomial, piecewise-linear, or piecewise-polynomial function of velocity, a user-defined function, or a constant value. You should also check the Zone Average Direction vector to be sure that a pressure rise occurs for forward flow through the fan. The Zone Average Direction, calculated by the solver, is the face-averaged direction vector for the fan zone. If this vector is pointing in the direction you want the fan to blow, do not select Reverse Fan Direction; if it is pointing in the opposite direction, select Reverse Fan Direction.

6.3.18.2.2.1. Polynomial, Piecewise-Linear, or Piecewise-Polynomial Function

Follow these steps to set a polynomial, piecewise-linear, or piecewise-polynomial function for the pressure jump:

1. Check that the Profile Specification of Pressure-Jump option is off in the Fan Dialog Box (p. 2110).

2. Choose polynomial, piecewise-linear, or piecewise-polynomial in the drop-down list to the right of Pressure-Jump. (If the function type you want is already selected, you can click the Edit... button to open the dialog box where you will define the function.)

3. In the dialog box that appears for the definition of the Pressure Jump function (for example, Figure 6.49: Polynomial Profile Dialog Box for Pressure Jump Definition (p. 338)), enter the appropriate values. These profile input dialog boxes are used the same way as the profile input dialog boxes for temperature-dependent properties. See Defining Properties Using Temperature-Dependent Functions (p. 412) to find out how to use them.

Figure 6.49: Polynomial Profile Dialog Box for Pressure Jump Definition

4. Set any of the optional parameters described below. (optional)

When you define the pressure jump using any of these types of functions, you can choose to limit the minimum and maximum velocity magnitudes used to calculate the pressure jump. Enabling the Limit...
**Polynomial Velocity Range** option limits the pressure jump when a **Min Velocity Magnitude** and a **Max Velocity Magnitude** are specified.

**Important**

The values corresponding to the **Min Velocity Magnitude** and the **Max Velocity Magnitude** do not limit the flow field velocity to this range. However, this range does limit the value of the pressure jump, which is a polynomial and a function of velocity, as seen in Equation 6.103 (p. 336). If the calculated normal velocity magnitude exceeds the **Max Velocity Magnitude** that has been specified, then the pressure jump at the **Max Velocity Magnitude** value will be used. Similarly, if the calculated velocity is less than the specified **Min Velocity Magnitude**, the pressure jump at the **Min Velocity Magnitude** will be substituted for the pressure jump corresponding to the calculated velocity.

You also have the option to use the mass-averaged velocity normal to the fan to determine a single pressure-jump value for all faces in the fan zone. Turning on **Calculate Pressure-Jump from Average Conditions** enables this option.

**6.3.18.2.2.2. Constant Value**

To define a constant pressure jump, follow these steps:

1. Turn off the **Profile Specification of Pressure-Jump** option in the Fan Dialog Box (p. 2110).
2. Choose **constant** in the drop-down list to the right of Pressure-Jump.
3. Enter the value for $\Delta p$ in the **Pressure-Jump** field.

You can follow the procedure below, if it is more convenient:

1. Turn on the **Profile Specification of Pressure-Jump** option.
2. Select **constant** in the drop-down list below **Pressure Jump Profile**, and enter the value for $\Delta p$ in the **Pressure Jump Profile** field.

**6.3.18.2.2.3. User-Defined Function or Profile**

For a user-defined pressure-jump function or a function defined in a boundary profile file, you will follow these steps:

1. Turn on the **Profile Specification of Pressure-Jump** option.
2. Choose the appropriate function in the drop-down list below **Pressure Jump Profile**.

See the **UDF Manual** for information about user-defined functions, and **Profiles** (p. 377) for details about profile files.

**6.3.18.2.2.4. Example: Determining the Pressure Jump Function**

This example shows you how to determine the function for the pressure jump. Consider the simple two-dimensional duct flow illustrated in **Figure 6.50: A Fan Located In a 2D Duct** (p. 340). Air at constant density enters the 2.0 m $\times$ 0.4 m duct with a velocity of 15 m/s. Centered in the duct is a fan.
Assume that the fan characteristics are as follows when the fan is operating at 2000 rpm:

<table>
<thead>
<tr>
<th>$Q$ (m$^3$/s)</th>
<th>$\Delta p$ (Pa)</th>
</tr>
</thead>
<tbody>
<tr>
<td>25</td>
<td>0.0</td>
</tr>
<tr>
<td>20</td>
<td>175</td>
</tr>
<tr>
<td>15</td>
<td>350</td>
</tr>
<tr>
<td>10</td>
<td>525</td>
</tr>
<tr>
<td>5</td>
<td>700</td>
</tr>
<tr>
<td>0</td>
<td>875</td>
</tr>
</tbody>
</table>

where $Q$ is the flow through the fan and $\Delta p$ is the pressure rise across the fan. The fan characteristics in this example follow a simple linear relationship between pressure rise and flow rate. To convert this into a relationship between pressure rise and velocity, the cross-sectional area of the fan must be known.

In this example, assuming that the duct is 1.0 m deep, this area is 0.4 m$^2$, so that the corresponding velocity values are as follows:

<table>
<thead>
<tr>
<th>$v$ (m/s)</th>
<th>$\Delta p$ (Pa)</th>
</tr>
</thead>
<tbody>
<tr>
<td>62.5</td>
<td>0.0</td>
</tr>
<tr>
<td>50.0</td>
<td>175</td>
</tr>
<tr>
<td>37.5</td>
<td>350</td>
</tr>
<tr>
<td>25.0</td>
<td>525</td>
</tr>
<tr>
<td>12.5</td>
<td>700</td>
</tr>
<tr>
<td>0</td>
<td>875</td>
</tr>
</tbody>
</table>

The polynomial form of this relationship is the following equation for a line:

$$\Delta p = 875 - 14v$$

(6.106)

### 6.3.18.2.3. Defining Discrete Phase Boundary Conditions for the Fan

If you are modeling a discrete phase of particles, you can set the fate of particle trajectories at the fan. See Setting Boundary Conditions for the Discrete Phase (p. 1189) for details.
6.3.18.2.4. Defining the Fan Swirl Velocity

If you want to set tangential and radial velocity fields on the fan surface to generate swirl in a 3D problem, follow these steps:

1. Turn on the **Swirl-Velocity Specification** option in the Fan Dialog Box (p. 2110).

2. Specify the fan’s axis of rotation by defining the axis origin (**Fan Origin**) and direction vector (**Fan Axis**).

3. Set the value for the radius of the fan’s hub (**Fan Hub Radius**). The default is $1 \times 10^{-6}$ to avoid division by zero in the polynomial.

4. Set the tangential and radial velocity functions as polynomial functions of radial distance, constant values, or user-defined functions.

**Important**

You must use SI units for all fan swirl velocity inputs.

6.3.18.2.4.1. Polynomial Function

To define a polynomial function for tangential or radial velocity, follow the steps below:

1. Check that the **Profile Specification of Tangential Velocity** or **Profile Specification of Radial Velocity** option is off in the Fan Dialog Box (p. 2110).

2. Enter the coefficients $f_n$ in Equation 6.104 (p. 336) or $g_n$ in Equation 6.105 (p. 336) in the **Tangential- or Radial-Velocity Polynomial Coefficients** field. Enter $f_{-1}$ first, then $f'_1$ etc. Separate each coefficient by a blank space. Remember that the first coefficient is for $\frac{1}{r}$.

6.3.18.2.4.2. Constant Value

To define a constant tangential or radial velocity, the steps are as follows:

1. Turn on the **Profile Specification of Tangential Velocity** or **Profile Specification of Radial Velocity** option in the Fan Dialog Box (p. 2110).

2. Select **constant** in the drop-down list under **Tangential** or **Radial Velocity Profile**.

3. Enter the value for $U_\theta$ or $U_r$ in the **Tangential** or **Radial Velocity Profile** field.

You can follow the procedure below, if it is more convenient:

1. Turn off the **Profile Specification of Tangential Velocity** or **Profile Specification of Radial Velocity** option in the Fan Dialog Box (p. 2110).

2. Enter the value for $U_\theta$ or $U_r$ in the **Tangential- or Radial-Velocity Polynomial Coefficients** field.

6.3.18.2.4.3. User-Defined Function or Profile

For a user-defined tangential or radial velocity function or a function contained in a profile file, follow the procedure below:
1. Turn on the **Profile Specification of Tangential** or **Radial Velocity** option.

2. Choose the appropriate function from the drop-down list under **Tangential** or **Radial Velocity Profile**.

See the **UDF Manual** for information about user-defined functions, and **Profiles (p. 377)** for details about profile files.

### 6.3.18.3. Postprocessing for Fans

#### 6.3.18.3.1. Reporting the Pressure Rise Through the Fan

You can use the **Surface Integrals Dialog Box (p. 2356)** to report the pressure rise through the fan, as described in **Surface Integration (p. 1755)**. There are two steps to this procedure:

1. Create a surface on each side of the fan zone. Use the **Transform Surface Dialog Box (p. 2484)** (as described in **Transforming Surfaces (p. 1599)**) to translate the fan zone slightly upstream and slightly downstream to create two new surfaces.

2. In the **Surface Integrals** dialog box, report the average **Static Pressure** just upstream and just downstream of the fan. You can then calculate the pressure rise through the fan.

#### 6.3.18.3.2. Graphical Plots

Graphical reports of interest with fans are as follows:

- Contours or profiles of **Static Pressure** and **Static Temperature**.
- XY plots of **Static Pressure** and **Static Temperature** vs position.

**Displaying Graphics (p. 1605)** explains how to generate graphical displays of data.

---

**Important**

When generating these plots, be sure to turn off the display of node values so that you can see the different values on each side of the fan. (If you display node values, the cell values on either side of the fan will be averaged to obtain a node value, and you will not see, for example, the pressure jump across the fan.)

### 6.3.19. Radiator Boundary Conditions

A lumped-parameter model for a heat exchange element (for example, a radiator or condenser), is available in ANSYS Fluent. The radiator boundary type allows you to specify both the pressure drop and heat transfer coefficient as functions of the velocity normal to the radiator.

A more detailed heat exchanger model is also available in ANSYS Fluent. See **Modeling Heat Exchangers (p. 847)** for details.

#### 6.3.19.1. Radiator Equations

##### 6.3.19.1.1. Modeling the Pressure Loss Through a Radiator

A radiator is considered to be infinitely thin, and the pressure drop through the radiator is assumed to be proportional to the dynamic head of the fluid, with an empirically determined loss coefficient that
you supply. That is, the pressure drop, $\Delta p$, varies with the normal component of velocity through the radiator, $v$, as follows:

\[
\Delta p = k_L \frac{1}{2} \rho v^2
\]

(6.107)

where $\rho$ is the fluid density, and $k_L$ is the non-dimensional loss coefficient, which can be specified as a constant or as a polynomial, piecewise-linear, or piecewise-polynomial function.

In the case of a polynomial, the relationship is of the form

\[
k_L = \sum_{n=1}^{N} r_n v^{n-1}
\]

(6.108)

where $r_n$ are polynomial coefficients and $v$ is the magnitude of the local fluid velocity normal to the radiator.

### 6.3.19.1.2. Modeling the Heat Transfer Through a Radiator

The heat flux from the radiator to the surrounding fluid is given as

\[
q = h \left( T_{\text{ext}} - T_{\text{air},d} \right)
\]

(6.109)

where $q$ is the heat flux, $T_{\text{air},d}$ is the temperature downstream of the heat exchanger (radiator), and $T_{\text{ext}}$ is the radiator temperature. The convective heat transfer coefficient, $h$, can be specified as a constant or as a polynomial, piecewise-linear, or piecewise-polynomial function.

For a polynomial, the relationship is of the form

\[
h = \sum_{n=0}^{N} h_n v^n ; \quad 0 \leq N \leq 7
\]

(6.110)

where $h_n$ are polynomial coefficients and $v$ is the magnitude of the local fluid velocity normal to the radiator in m/s.

To define the actual heat flux ($q$), specify a **Temperature** of absolute zero (0 K, 0 °R, −273.15 °C, −459.67 °F), and set the constant **Heat Flux** value.

To define the radiator temperature, enter the value for $T_{\text{ext}}$ in the **Temperature** field. To define the **Heat-Transfer-Coefficient** ($h$), you can specify a polynomial, piecewise-linear, or piecewise-polynomial function of velocity, or a constant value.

$q$ (either the entered value or the value calculated using Equation 6.109 (p. 343)) is integrated over the radiator surface area.

Fluent does not allow you to specify a value less than absolute zero for the radiator temperature.

### 6.3.19.1.2.1. Calculating the Heat Transfer Coefficient

To model the thermal behavior of the radiator, you must supply an expression for the heat transfer coefficient, $h$, as a function of the fluid velocity through the radiator, $v$. To obtain this expression, consider the heat balance equation:
\[ q = \frac{\dot{m}c_p \Delta T}{A} = h \left( T_{air,d} - T_{ext} \right) \tag{6.111} \]

where

\[ q = \text{heat flux (W/m}^2\text{)} \]
\[ \dot{m} = \text{fluid mass flow rate (kg/s)} \]
\[ c_p = \text{specific heat capacity of fluid (J/kg-K)} \]
\[ h = \text{empirical heat transfer coefficient (W/m}^2\text{-K)} \]
\[ T_{ext} = \text{external temperature (reference temperature for the liquid) (K)} \]
\[ T_{air,d} = \text{temperature downstream from the heat exchanger (K)} \]
\[ A = \text{heat exchanger frontal area (m}^2\text{)} \]

Equation 6.111 (p. 344) can be rewritten as

\[ q = \frac{\dot{m}c_p \left( T_{air,u} - T_{air,d} \right)}{A} = h \left( T_{air,d} - T_{ext} \right) \tag{6.112} \]

where \( T_{air,u} \) is the upstream air temperature. The heat transfer coefficient, \( h \), can therefore be computed as

\[ h = \frac{\dot{m}c_p \left( T_{air,u} - T_{air,d} \right)}{A \left( T_{air,d} - T_{ext} \right)} \tag{6.113} \]

or, in terms of the fluid velocity,

\[ h = \frac{\rho v c_p \left( T_{air,u} - T_{air,d} \right)}{\frac{T_{air,d} - T_{ext}}{T_{air,d} - T_{ext}}} \tag{6.114} \]

### 6.3.19.2. User Inputs for Radiators

Once the radiator zone has been identified (in the **Boundary Conditions** task page), you will set all modeling inputs for the radiator in the **Radiator Dialog Box** (p. 2151) (**Figure 6.51: The Radiator Dialog Box (p. 345)**), which is opened from the **Boundary Conditions Task Page** (p. 2102) (as described in Setting **Cell Zone and Boundary Conditions** (p. 204)).
The inputs for a radiator are as follows:

1. Identify the radiator zone.

2. Define the pressure loss coefficient.

3. Define either the heat flux or the heat transfer coefficient and radiator temperature.

   *If defining the heat flux, specify the Temperature as absolute zero.*

4. Define the discrete phase boundary condition for the radiator (for discrete phase calculations).

### 6.3.19.2.1. Identifying the Radiator Zone

Since the radiator is considered to be infinitely thin, it must be modeled as the interface between cells, rather than a cell zone. Therefore the radiator zone is a type of internal face zone (where the faces are line segments in 2D or triangles/quadrilaterals in 3D). If, when you read your mesh into ANSYS Fluent, the radiator zone is identified as an **interior** zone, use the **Boundary Conditions Task Page** (p. 2102) (as described in **Changing Cell and Boundary Zone Types** (p. 203)) to change the appropriate **interior** zone to a **radiator** zone.

### Boundary Conditions

Once the interior zone has been changed to a radiator zone, you can open the **Radiator** dialog box and specify the loss coefficient and heat flux information.

### 6.3.19.2.2. Defining the Pressure Loss Coefficient Function

To define the pressure loss coefficient $k_I$, you can specify a polynomial, piecewise-linear, or piecewise-polynomial function of velocity, or a constant value.
6.3.19.2.2.1. Polynomial, Piecewise-Linear, or Piecewise-Polynomial Function

Follow these steps to set a polynomial, piecewise-linear, or piecewise-polynomial function for the pressure loss coefficient:

1. Choose polynomial, piecewise-linear, or piecewise-polynomial in the drop-down list to the right of Loss Coefficient. (If the function type you want is already selected, you can click the Edit... button to open the dialog box where you will define the function.)

2. In the dialog box that appears for the definition of the Loss Coefficient function (for example, Figure 6.52: Polynomial Profile Dialog Box for Loss Coefficient Definition (p. 346)), enter the appropriate values. These profile input dialog boxes are used the same way as the profile input dialog boxes for temperature-dependent properties. See Defining Properties Using Temperature-Dependent Functions (p. 412) to find out how to use them.

![Figure 6.52: Polynomial Profile Dialog Box for Loss Coefficient Definition](image)

6.3.19.2.2.2. Constant Value

To define a constant loss coefficient, follow these steps:

1. Choose constant in the Loss Coefficient drop-down list.

2. Enter the value for $k_L$ in the Loss Coefficient field.

6.3.19.2.2.3. Example: Calculating the Loss Coefficient

This example shows you how to determine the loss coefficient function. Consider the simple two-dimensional duct flow of air through a water-cooled radiator, shown in Figure 6.53: A Simple Duct with a Radiator (p. 347).
The radiator characteristics must be known empirically. For this case, assume that the radiator to be modeled yields the test data shown in Table 6.2: Air-side Radiator Data (p. 347), which was taken with a waterside flow rate of 7 kg/min and an inlet water temperature of 400.0 K. To compute the loss coefficient, it is helpful to construct a table with values of the dynamic head, $\frac{1}{2} \rho v^2$, as a function of pressure drop, $\Delta p$, and the ratio of these two values, $k_L$ (from Equation 6.107 (p. 343)). (The air density, defined in Figure 6.53: A Simple Duct with a Radiator (p. 347), is 1.0 kg/m$^3$.) The reduced data are shown in Table 6.3: Reduced Radiator Data (p. 347).

**Table 6.2: Air-side Radiator Data**

<table>

</tbody>
</table>

The loss coefficient is a linear function of the velocity, decreasing as the velocity increases. The form of this relationship is

$$k_L = 7.0 - 0.2v$$

where $v$ is now the absolute value of the velocity through the radiator.
6.3.19.2.3. Defining the Heat Flux Parameters

As mentioned in Radiator Equations (p. 342), you can either define the actual heat flux \( q \) in the Heat Flux field, or set the heat transfer coefficient and radiator temperature \( h, T_{\text{ext}} \). All inputs are in the Radiator Dialog Box (p. 2151).

To define the actual heat flux, specify a Temperature of 0 K, and set the constant Heat Flux value.

To define the radiator temperature, enter the value for \( T_{\text{ext}} \) in the Temperature field. To define the Heat-Transfer-Coefficient, you can specify a polynomial, piecewise-linear, or piecewise-polynomial function of velocity, or a constant value.

6.3.19.2.3.1. Polynomial, Piecewise-Linear, or Piecewise-Polynomial Function

Follow these steps to set a polynomial, piecewise-linear, or piecewise-polynomial function for the heat transfer coefficient:

1. Choose polynomial, piecewise-linear, or piecewise-polynomial in the drop-down list to the right of Heat-Transfer-Coefficient. (If the function type you want is already selected, you can click the Edit... button to open the dialog box where you will define the function.)

2. In the dialog box that appears for the definition of the Heat-Transfer-Coefficient function, enter the appropriate values. These profile input dialog boxes are used the same way as the profile input dialog boxes for temperature-dependent properties. See Defining Properties Using Temperature-Dependent Functions (p. 412) to find out how to use them.

6.3.19.2.3.2. Constant Value

To define a constant heat transfer coefficient, follow these steps:

1. Choose constant in the Heat-Transfer-Coefficient drop-down list.

2. Enter the value for \( h \) in the Heat-Transfer-Coefficient field.

6.3.19.2.3.3. Example: Determining the Heat Transfer Coefficient Function

This example shows you how to determine the function for the heat transfer coefficient. Consider the simple two-dimensional duct flow of air through a water-cooled radiator, shown in Figure 6.53: A Simple Duct with a Radiator (p. 347).

The data supplied in Table 6.2: Air-side Radiator Data (p. 347) along with values for the air density \((1.0 \text{ kg/m}^3)\) and specific heat \((1000 \text{ J/kg-K})\) can be used to obtain the following values for the heat transfer coefficient \( h \):

<table>
<thead>
<tr>
<th>Velocity (m/s)</th>
<th>( h ) (W/m(^2)-K)</th>
</tr>
</thead>
<tbody>
<tr>
<td>5.0</td>
<td>2142.9</td>
</tr>
<tr>
<td>10.0</td>
<td>2903.2</td>
</tr>
<tr>
<td>15.0</td>
<td>3750.0</td>
</tr>
</tbody>
</table>

The heat transfer coefficient obeys a second-order polynomial relationship (fit to the points in the table above) with the velocity, which is of the form...
Note that the velocity $v$ is assumed to be the absolute value of the velocity passing through the radiator.

### 6.3.19.2.4. Defining Discrete Phase Boundary Conditions for the Radiator

If you are modeling a discrete phase of particles, you can set the fate of particle trajectories at the radiator. See Setting Boundary Conditions for the Discrete Phase (p. 1189) for details.

### 6.3.19.3. Postprocessing for Radiators

#### 6.3.19.3.1. Reporting the Radiator Pressure Drop

You can use the Surface Integrals Dialog Box (p. 2356) to report the pressure drop across the radiator, as described in Surface Integration (p. 1755). There are two steps to this procedure:

1. Create a surface on each side of the radiator zone. Use the Transform Surface Dialog Box (p. 2484) (as described in Transforming Surfaces (p. 1599)) to translate the radiator zone slightly upstream and slightly downstream to create two new surfaces.

2. In the Surface Integrals dialog box, report the average Static Pressure just upstream and just downstream of the radiator. You can then calculate the pressure drop across the radiator.

To check this value against the expected value based on Equation 6.107 (p. 343), you can use the Surface Integrals dialog box to report the average normal velocity through the radiator. (If the radiator is not aligned with the $x$, $y$, or $z$ axis, you will need to use the Custom Field Function Calculator Dialog Box (p. 2448) to generate a function for the velocity normal to the radiator.) Once you have the average normal velocity, you can use Equation 6.108 (p. 343) to determine the loss coefficient and then Equation 6.107 (p. 343) to calculate the expected pressure loss.

#### 6.3.19.3.2. Reporting Heat Transfer in the Radiator

To determine the temperature rise across the radiator, follow the procedure outlined above for the pressure drop to generate surfaces upstream and downstream of the radiator. Then use the Surface Integrals Dialog Box (p. 2356) (as for the pressure drop report) to report the average Static Temperature on each surface. You can then calculate the temperature rise across the radiator.

#### 6.3.19.3.3. Graphical Plots

Graphical reports of interest with radiators are as follows:

- Contours or profiles of Static Pressure and Static Temperature.
- XY plots of Static Pressure and Static Temperature vs position.

Displaying Graphics (p. 1605) explains how to generate graphical displays of data.

---

**Important**

When generating these plots, be sure to turn off the display of node values so that you can see the different values on each side of the radiator. (If you display node values, the cell values on either side of the radiator will be averaged to obtain a node value, and you will not see, for example, the pressure loss across the radiator.)
6.3.20. Porous Jump Boundary Conditions

Porous jump conditions are used to model a thin “membrane” that has known velocity (pressure-drop) characteristics. It is essentially a 1D simplification of the porous media model available for cell zones. Examples of uses for the porous jump condition include modeling pressure drops through screens and filters, and modeling radiators when you are not concerned with heat transfer. This simpler model should be used whenever possible (instead of the full porous media model) because it is more robust and yields better convergence.

The thin porous medium has a finite thickness over which the pressure change is defined as a combination of Darcy’s Law and an additional inertial loss term:

\[
\Delta p = - \left( \frac{\mu}{\alpha} v + C_2 \frac{1}{2} \rho v^2 \right) \Delta m
\]  \[\text{(6.117)}\]

where \(\mu\) is the laminar fluid viscosity, \(\alpha\) is the permeability of the medium, \(C_2\) is the pressure-jump coefficient, \(v\) is the velocity normal to the porous face, and \(\Delta m\) is the thickness of the medium. Appropriate values for \(\alpha\) and \(C_2\) can be calculated using the techniques described in User Inputs for Porous Media (p. 229).

Note

In some cases, the pressure-based coupled solver with porous jump boundary conditions may suffer from convergence issues that do not respond to changes in the coupled solver settings. This behavior depends on the specific flow configuration and porous jump boundary condition values. If convergence instability is observed using the coupled pressure-based solver, it is recommended that you change the pressure-velocity coupling to one of the segregated schemes.

6.3.20.1. User Inputs for the Porous Jump Model

Once the porous jump zone has been identified (in the Boundary Conditions task page), you will set all modeling inputs for the porous jump in the Porous Jump Dialog Box (p. 2136) (Figure 6.54: The Porous Jump Dialog Box (p. 350)), which is opened from the Boundary Conditions Task Page (p. 2102) (as described in Setting Cell Zone and Boundary Conditions (p. 204)).

Figure 6.54: The Porous Jump Dialog Box

The inputs required for the porous jump model are as follows:
1. Identify the porous-jump zone.

2. Set the **Face Permeability** of the medium ($\alpha$ in Equation 6.117 (p. 350)).

3. Set the **Porous Medium Thickness** ($\Delta m$).

4. Set the **Pressure-Jump Coefficient** ($C_2$).

---

**Note**

The unit for the pressure-jump coefficient ($C_2$) is the inverse of length. Should you want to define different units, you can do so by opening the Units dialog box and selecting `length-inverse` from the Quantities list.

---

5. Define the discrete phase boundary condition for the porous jump (for discrete phase calculations).

6. If you have enabled the solar load model, define the **Solar Boundary Conditions** for the porous jump. These settings allow you to define the boundary such that it acts as a semi-transparent surface (with respect to the solar radiation calculation only), and therefore allows a portion of the solar radiation to pass through it. See Solar Ray Tracing (p. 829) for details.

### 6.3.20.1.1. Identifying the Porous Jump Zone

Since the porous jump model is a 1D simplification of the porous media model, the porous-jump zone must be modeled as the interface between cells, rather than a cell zone. Therefore the porous-jump zone is a type of internal face zone (where the faces are line segments in 2D or triangles/quadrilaterals in 3D). If the porous-jump zone is not identified as such by default when you read in the mesh (that is, if it is identified as another type of internal face zone), you can use the Boundary Conditions Task Page (p. 2102) to change the appropriate face zone to a porous-jump zone.

Define → Boundary Conditions...

The procedure for changing a zone’s type is described in Changing Cell and Boundary Zone Types (p. 203). Once the zone has been changed to a porous jump, you can open the Porous Jump Dialog Box (p. 2136) (as described in Setting Cell Zone and Boundary Conditions (p. 204)) and specify the porous jump parameters listed above.

### 6.3.20.1.2. Defining Discrete Phase Boundary Conditions for the Porous Jump

If you are modeling a discrete phase of particles, you can set the fate of particle trajectories at the porous jump. See Setting Boundary Conditions for the Discrete Phase (p. 1189) for details.

### 6.3.20.2. Postprocessing for the Porous Jump

Postprocessing suggestions for a problem that includes a porous jump are the same as for porous media problems. See Postprocessing for Porous Media (p. 246).

### 6.4. Non-Reflecting Boundary Conditions

The standard pressure boundary condition, imposed on the boundaries of artificially truncated domain, results in the reflection of the outgoing waves. As a consequence, the interior domain will contain spurious wave reflections. Many applications require precise control of the wave reflections from the
domain boundaries to obtain accurate flow solutions. Non-reflecting boundary conditions provide a special treatment to the domain boundaries to control these spurious wave reflections.

In ANSYS Fluent, two types of non-reflecting boundary conditions (NRBC) are available:

- turbo-specific NRBC
- general NRBC

In the density-based solver, both NRBC methods are available for flows using the compressible ideal-gas law.

In the pressure-based solver, only the general NRBC method is available for transient simulations and compressible flows (including the ideal-gas law, real gas law, species transport, and compressible mixture models).

Information about non-reflecting boundary conditions (NRBCs) is provided in the following sections.

6.4.1. Turbo-Specific Non-Reflecting Boundary Conditions

6.4.1.1. Overview

The standard pressure boundary conditions for compressible flow fix specific flow variables at the boundary (for example, static pressure at an outlet boundary). As a result, pressure waves incident on the boundary will reflect in an unphysical manner, leading to local errors. The effects are more pronounced for internal flow problems where boundaries are usually close to geometry inside the domain, such as compressor or turbine blade rows.

The turbo-specific non-reflecting boundary conditions permit waves to “pass” through the boundaries without spurious reflections. The method used in ANSYS Fluent is based on the Fourier transformation of solution variables at the non-reflecting boundary [29] (p. 2558). Similar implementations have been investigated by other authors [62] (p. 2560) [84] (p. 2561). The solution is rearranged as a sum of terms corresponding to different frequencies, and their contributions are calculated independently. While the method was originally designed for axial turbomachinery, it has been extended for use with radial turbomachinery.

6.4.1.2. Limitations

Note the following limitations of turbo-specific NRBCs:

- They are available only with the density-based solver (explicit or implicit).
- The current implementation applies to steady compressible flows, with the density calculated using the ideal gas law.
• Inlet and outlet boundary conditions must be pressure inlets and outlets only.

  **Important**

  Note that the pressure inlet boundaries must be set to the cylindrical coordinate flow specification method when turbo-specific NRBCs are used.

• Quad-mapped (structured) surface meshes must be used for inflow and outflow boundaries in a 3D geometry (that is, triangular or quad-paved surface meshes are not allowed). See Figure 6.55: Mesh and Prescribed Boundary Conditions in a 3D Axial Flow Problem (p. 354) and Figure 6.56: Mesh and Prescribed Boundary Conditions in a 3D Radial Flow Problem (p. 354) for examples.

  **Important**

  Note that you may use unstructured meshes in 2D geometries (Figure 6.57: Mesh and Prescribed Boundary Conditions in a 2D Case (p. 355)), and an unstructured mesh may be used away from the inlet and outlet boundaries in 3D geometries.

• The turbo-specific NRBC \[29\] (p. 2558) has been extended for use on 3D geometries \[84\] (p. 2561) by decoupling the tangential flow variations from the radial variations. This approximation works best for geometries with a blade pitch that is small compared to the radius of the geometry.

• Reverse flow on the inflow and outflow boundaries are not allowed. If strong reverse flow is present, then you should consider using the General NRBCs instead.

• NRBCs are not compatible with species transport models. They are mainly used to solve ideal-gas single-species flow.
Figure 6.55: Mesh and Prescribed Boundary Conditions in a 3D Axial Flow Problem

Figure 6.56: Mesh and Prescribed Boundary Conditions in a 3D Radial Flow Problem
6.4.1.3. Theory

Turbo-specific NRBCs are based on Fourier decomposition of solutions to the linearized Euler equations. The solution at the inlet and outlet boundaries is circumferentially decomposed into Fourier modes, with the 0th mode representing the average boundary value (which is to be imposed as a user input), and higher harmonics that are modified to eliminate reflections [84] (p. 2561).

6.4.1.3.1. Equations in Characteristic Variable Form

In order to treat individual waves, the linearized Euler equations are transformed to characteristic variable \( (C_i) \) form. If we first consider the 1D form of the linearized Euler equations, it can be shown that the characteristic variables \( C_i \) are related to the solution variables as follows:

\[
\tilde{Q} = T^{-1} C
\]

(6.118)

where
Cell Zone and Boundary Conditions

where $\bar{a}$ is the average acoustic speed along a boundary zone, $\bar{\rho}, \bar{\mathbf{u}}, \bar{p}$, and $\bar{\mathbf{p}}$ represent perturbations from a uniform condition (for example, $\bar{\rho} = \rho - \bar{\rho}, \bar{p} = p - \bar{p}$, etc.).

Note that the analysis is performed using the cylindrical coordinate system. All overlined (averaged) flow field variables (for example, $\bar{\rho}, \bar{\mathbf{u}}, \bar{p}$) are intended to be averaged along the pitchwise direction.

In quasi-3D approaches [29] (p. 2558) [62] (p. 2560) [84] (p. 2561), a procedure is developed to determine the changes in the characteristic variables, denoted by $\delta C_i$, at the boundaries such that waves will not reflect. These changes in characteristic variables are determined as follows:

$$\delta C = T \cdot \delta \mathbf{Q}$$

where

$$\delta \mathbf{C} = \begin{bmatrix} \delta C_1 \\ \delta C_2 \\ \delta C_3 \\ \delta C_4 \\ \delta C_5 \end{bmatrix}, \quad T = \begin{bmatrix} -\bar{a}^{-2} & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix}, \quad \delta \mathbf{Q} = \begin{bmatrix} \delta \rho \\ \delta \mathbf{u}_a \\ \delta \mathbf{u}_t \\ \delta \mathbf{u}_r \\ \delta p \end{bmatrix}$$

The changes to the outgoing characteristics — one characteristic for subsonic inflow ($\delta C_3$), and four characteristics for subsonic outflow ($\delta C_1, \delta C_2, \delta C_3, \delta C_4$) — are determined from extrapolation of the flow field variables using Equation 6.120 (p. 356).

The changes in the incoming characteristics — four characteristics for subsonic inflow ($\delta C_1, \delta C_2, \delta C_3, \delta C_4$), and one characteristic for subsonic outflow ($\delta C_3$) — are split into two components: average change along the boundary ($\delta \bar{C}_3$), and local changes in the characteristic variable due to harmonic variation along the boundary ($\delta C_{iL}$). The incoming characteristics are therefore given by

$$\delta C_{i,j} = \delta C_{iold,j} + \sigma \left( \delta C_{inew,j} - \delta C_{iold,j} \right)$$

$$\delta C_{inew,j} = \left( \delta \bar{C}_3 + \delta C_{iL,j} \right)$$
where \( i = 1, 2, 3, 4 \) on the inlet boundary or \( i = 5 \) on the outlet boundary, and \( j = 1, \ldots, N \) is the grid index in the pitchwise direction including the periodic point once. The under-relaxation factor \( \sigma \) has a default value of 0.75. Note that this method assumes a periodic solution in the pitchwise direction.

The flow is decomposed into mean and circumferential components using Fourier decomposition. The 0th Fourier mode corresponds to the average circumferential solution, and is treated according to the standard 1D characteristic theory. The remaining parts of the solution are described by a sum of harmonics, and treated as 2D non-reflecting boundary conditions [29] (p. 2558).

### 6.4.1.3.2. Inlet Boundary

For subsonic inflow, there is one outgoing characteristic \( \delta C_2 \) determined from Equation 6.120 (p. 356), and four incoming characteristics \( \delta C_1, \delta C_3, \delta C_4 \) calculated using Equation 6.122 (p. 356). The average changes in the incoming characteristics are computed from the requirement that the entropy \( s \), radial and tangential flow angles \( \alpha_r, \alpha_t \), and stagnation enthalpy \( h_0 \) are specified. Note that in ANSYS Fluent you can specify \( p_0 \) and \( T_0 \) at the inlet, from which \( s_{in} \) and \( h_{0, in} \) are easily obtained. This is equivalent to forcing the following four residuals to be zero:

\[
R_1 = \overline{p} (\bar{s} - s_{in})
\]

\[
R_2 = \rho \overline{a} (\bar{u}_t - u_a \tan \alpha_t)
\]

\[
R_3 = \rho \overline{a} (\bar{u}_r - u_a \tan \alpha_r)
\]

\[
R_4 = \rho (\overline{h}_0 - h_{0, in})
\]

where

\[
s_{in} = \gamma \ln \left( \frac{T_0}{p_{in}} \right) - (\gamma - 1) \ln \left( \frac{p_{in}}{p_0} \right)
\]

\[
h_{0, in} = c_p T_0
\]

The average characteristic is then obtained from residual linearization as follows (see also Figure 6.58: Prescribed Inlet Angles (p. 358))

\[
\left\{ \begin{array}{c}
\delta C_1 \\
\delta C_2 \\
\delta C_3 \\
\delta C_4 \\
\end{array} \right\} = \left[ \begin{array}{cccc}
-1 & 0 & 0 & 0 \\
M_1 & -M_1 \tan \alpha_t & 0 & 0 \\
M_2 & 0 & -M_1 \tan \alpha_t & 0 \\
M_3 & M_4 & 0 & -2 \\
\end{array} \right] \left\{ \begin{array}{c}
R_1 \\
R_2 \\
R_3 \\
R_4 \\
\end{array} \right\}
\]

where

\[
M_a = \frac{\bar{a}}{a}
\]

\[
M_t = \frac{\bar{u}_t}{a}
\]
\[ M_r = \frac{\bar{u}_r}{\bar{a}} \]  

and

\[ M = 1 + M_a - M_r \tan \alpha_t + M_r \tan \alpha_r \]  
\[ M_i = -1 - M_a - M_r \tan \alpha_r \]  
\[ M_2 = -1 - M_a - M_t \tan \alpha_t \]

**Figure 6.58: Prescribed Inlet Angles**

where

\[ |v| = \sqrt{u_t^2 + u_r^2 + u_a^2} \]  
\[ e_t = \frac{u_t}{|v|} \]  
\[ e_r = \frac{u_r}{|v|} \]  
\[ e_a = \frac{u_a}{|v|} \]  
\[ \tan \alpha_t = \frac{e_t}{e_a} \]  
\[ \tan \alpha_r = \frac{e_r}{e_a} \]

To address the local characteristic changes at each \( j \) grid point along the inflow boundary, the following relations are developed [29] (p. 2558) [84] (p. 2561):
\[
\begin{align*}
\delta C_{1L_j} &= \bar{p} (s_j - \bar{s}) \\
\delta C_{2L_j} &= C'_2 - \bar{p} \bar{a} (u_{t_j} - \bar{u}_t) \\
\delta C_{3L_j} &= -\bar{p} \bar{a} (u_{r_j} - \bar{u}_r) \\
\delta C_{4L_j} &= -\frac{2}{(1+M_{a_j})} \left( \frac{1}{\gamma-1} \delta C_{1L_j} \right. \\
& \left. \left. \left. + M_{t_j} \delta C_{2L_j} + M_{r_j} \delta C_{3L_j} \right) - \bar{p} \left( h_{0_j} - \bar{h}_0 \right) \right) \\
\end{align*}
\]

(6.143)

Note that the relation for the first and fourth local characteristics force the local entropy and stagnation enthalpy to match their average steady-state values.

The characteristic variable \( C'_2 \) is computed from the inverse discrete Fourier transform of the second characteristic. The discrete Fourier transform of the second characteristic in turn is related to the discrete Fourier transform of the fifth characteristic. Hence, the characteristic variable \( C'_2 \) is computed along the pitch as follows:

\[
C'_2 = 2\Re \left( \sum_{n=1}^{\frac{N}{2}-1} \hat{C}_{2, n} \exp \left( i2\pi n \frac{\theta_j - \theta_1}{\theta_N - \theta_1} \right) \right) 
\]

(6.144)

The Fourier coefficients \( C'_{2, n} \) are related to a set of equidistant distributed characteristic variables \( C'_{5, j} \) by the following [62] (p. 2560):

\[
\hat{C}_{2, n} = \begin{cases} 
-\frac{\bar{u}_t + B}{N (\bar{a} + \bar{u}_a)} \sum_{j=1}^{N} C'_{5, j} \exp \left( -i2\pi \frac{\beta j n}{N} \right) & \beta > 0 \\
-\frac{\bar{u}_t + B}{\bar{a} + \bar{u}_a} C'_{5, j} & \beta < 0 
\end{cases} 
\]

(6.145)

where

\[
B = \begin{cases} 
i\sqrt{\beta} & \beta > 0 \\
\text{sign} (\bar{u}_t) \sqrt{|\beta|} & \beta < 0 
\end{cases} 
\]

(6.146)

and

\[
\beta = \bar{a}^2 - \bar{u}_a^2 - \bar{u}_t^2 
\]

(6.147)

The set of equidistributed characteristic variables \( C'_{5, j} \) is computed from arbitrary distributed \( C_{5, j} \) by using a cubic spline for interpolation, where

\[
C_{5, j} = -\bar{p} \bar{a} \left( u_{a_j} - \bar{u}_a \right) + \left( p_j - \bar{p} \right) 
\]

(6.148)
For supersonic inflow the user-prescribed static pressure \( p_{s_{\text{in}}} \) along with total pressure \( p_{0_{\text{in}}} \) and total temperature \( T_{0_{\text{in}}} \) are sufficient for determining the flow condition at the inlet.

### 6.4.1.3.3. Outlet Boundary

For subsonic outflow, there are four outgoing characteristics \( \delta C_1, \delta C_2, \delta C_3, \) and \( \delta C_4 \) calculated using Equation 6.120 (p. 356), and one incoming characteristic \( \delta C_3' \) determined from Equation 6.122 (p. 356). The average change in the incoming fifth characteristic is given by

\[
\delta C_5 = -2 \left( \bar{p} - p_{out} \right)
\]  

(6.149)

where \( \bar{p} \) is the current averaged pressure at the exit plane and \( p_{out} \) is the desirable average exit pressure (this value is specified by you for single-blade calculations or obtained from the assigned profile for mixing-plane calculations). The local changes \( \delta C_{5L_j} \) are given by

\[
\delta C_{5L_j} = C_5' + \bar{p} a \left( u_{a_j} - \bar{u}_a \right) - \left( p_j - \bar{p} \right)
\]  

(6.150)

The characteristic variable \( C_5' \) is computed along the pitch as follows:

\[
C_5' = 2R \left( \frac{N - 1}{2} \sum_{n=1}^{N - 1} \hat{C}_{5n} \exp \left( i2\pi n \frac{\theta_j - \theta_1}{\theta_N - \theta_1} \right) \right)
\]  

(6.151)

The Fourier coefficients \( \hat{C}_{5n} \) are related to two sets of equidistantly distributed characteristic variables \((C_2^*_{j} \) and \( C_4^*_{j} \) respectively) and given by the following [62] (p. 2560):

\[
\hat{C}_{5n} = \begin{cases} 
A_2 \sum_{j=1}^{N} C_2^*_{j} \exp \left( i2\pi \frac{jn}{N} \right) - A_4 \sum_{j=1}^{N} C_4^*_{j} \exp \left( i2\pi \frac{jn}{N} \right) & \beta > 0 \\
A_2 C_2^* - A_4 C_4^* & \beta < 0 
\end{cases}
\]  

(6.152)

where

\[
A_2 = \frac{2 \bar{u}_a}{B - \bar{u}_t}
\]  

(6.153)

\[
A_4 = \frac{B + \bar{u}_t}{B - \bar{u}_t}
\]  

(6.154)

The two sets of equidistributed characteristic variables \((C_2^*_{j} \) and \( C_4^*_{j} \) are computed from arbitrarily distributed \( C_2_{j} \) and \( C_4_{j} \) characteristics by using a cubic spline for interpolation, where

\[
C_2_{j} = \bar{p} a \left( u_{t_j} - \bar{u}_t \right)
\]  

(6.155)

\[
C_4_{j} = \bar{p} a \left( u_{a_j} - \bar{u}_a \right) + \left( p_j - \bar{p} \right)
\]  

(6.156)
For supersonic outflow all flow field variables are extrapolated from the interior.

### 6.4.1.3.4. Updated Flow Variables

Once the changes in the characteristics are determined on the inflow or outflow boundaries, the changes in the flow variables \( \delta Q \) can be obtained from Equation 6.120 (p. 356). Therefore, the values of the flow variables at the boundary faces are as follows:

\[
p_j = p_j + \delta p \quad (6.157)
\]

\[
u_a_j = u_a_j + \delta u_a \quad (6.158)
\]

\[
u_t_j = u_t_j + \delta u_t \quad (6.159)
\]

\[
u_r_j = u_r_j + \delta u_r \quad (6.160)
\]

\[
T_j = T_j + \delta T \quad (6.161)
\]

### 6.4.1.4. Using Turbo-Specific Non-Reflecting Boundary Conditions

**Important**

If you intend to use turbo-specific NRBCs in conjunction with the density-based implicit solver, it is recommended that you first converge the solution before turning on turbo-specific NRBCs, then converge it again with turbo-specific NRBCs turned on. If the solution is diverging, then you should lower the CFL number. These steps are necessary because only approximate flux Jacobians are used for the pressure-inlet and pressure-outlet boundaries when turbo-specific NRBCs are activated with the density-based implicit solver.

The procedure for using the turbo-specific NRBCs is as follows:

1. Turn on the turbo-specific NRBCs using the **non-reflecting-bc** text command:

   define → boundary-conditions → non-reflecting-bc → turbo-specific-nrbc → enable?

   If you are not sure whether or not NRBCs are turned on, use the **show-status** text command.

2. Perform NRBC initialization using the **initialize** text command:

   define → boundary-conditions → non-reflecting-bc → turbo-specific-nrbc → initialize

   If the initialization is successful, a summary printout of the domain extent will be displayed. If the initialization is not successful, an error message will be displayed indicating the source of the
problem. The initialization will set up the pressure-inlet and pressure-outlet boundaries for use with turbo-specific NRBCs.

**Important**

Note that the pressure inlet boundaries must be set to the cylindrical coordinate flow specification method when turbo-specific NRBCs are used.

3. If necessary, modify the parameters in the set/ submenu:

   define → boundary-conditions → non-reflecting-bc → turbo-specific-nrbc → set

   **under-relaxation**
   
   allows you to set the value of the under-relaxation factor $\sigma$ in Equation 6.122 (p. 356). The default value is 0.75.

   **discretization**
   
   allows you to set the discretization scheme. The default is to use higher-order reconstruction if available.

   **verbosity**
   
   allows you to control the amount of information printed to the console during an NRBC calculation.
   
   • 0: silent
   
   • 1: basic information (default)
   
   • 2: detailed information (for debugging purposes only)

### 6.4.1.4.1. Using the NRBCs with the Mixing-Plane Model

If you want to use the NRBCs with the mixing-plane model you must define the mixing plane interfaces as pressure-outlet and pressure-inlet zone type pairs.

**Important**

Turbo-specific NRBCs should not be used with the mixing-plane model if reverse flow is present across the mixing-plane.

### 6.4.1.4.2. Using the NRBCs in Parallel ANSYS Fluent

When the turbo-specific NRBCs are used in conjunction with the parallel solver, all cells in each boundary zone, where NRBCs will be applied, must be located or contained within a single partition. You can ensure this by manually partitioning the mesh (see Partitioning the Mesh Manually and Balancing the Load (p. 1856) for more information).

### 6.4.2. General Non-Reflecting Boundary Conditions

Information about general NRBCs is provided in the following sections.

**6.4.2.1. Overview**
6.4.2.1. Overview

The general non-reflecting boundary conditions in ANSYS Fluent are based on characteristic wave relations derived from the Euler equations. In the density-based solver, the non-reflecting boundary conditions are applied only on pressure-outlet boundary conditions. In the pressure-based solver they are applied on pressure-inlet, pressure-outlet, velocity-inlet and mass-flux boundary conditions. To obtain the primitive flow quantities \((P, u, v, w, T)\), reformulated Euler equations are solved on the boundary of the domain in an algorithm similar to the flow equations applied to the interior of the domain.

Unlike the turbo-specific NRBC, the general NRBC method is not restricted by geometric constraints or mesh type. However, good cell skewness near the boundaries where the NRBCs can be applied for better convergence.

6.4.2.2. Restrictions and Limitations

Note the following restrictions and limitations on the general NRBCs:

- The general NRBC is not available if the target mass flow rate is activated in the pressure-outlet dialog box.

- The general NRBC using the density-based solver is available only with compressible flow while using the ideal-gas law.

  **Important**

  The general NRBC using the density-based solver should not be used with the wet steam or real gas models.

- The general NRBCs using the density-based solver are not compatible with species transport and mixture fraction transport models (for premixed and partially-premixed models). They are mainly used to solve ideal-gas single-component flow.

- The general NRBCs using the pressure-based solver are not compatible with steady-state cases, all multiphase models, and compressible liquids models.

6.4.2.3. Theory

General NRBCs are derived by first recasting the Euler equations in an orthogonal coordinate system \((x_1, x_2, x_3)\) such that one of the coordinates, \(x_1\), is normal to the boundary Figure 6.59: The Local Orthogonal Coordinate System onto which Euler Equations are Recasted for the General NRBC Method (p. 365). The characteristic analysis \([109]\) (p. 2562) \([110]\) (p. 2563) is then used to modify terms corresponding to waves propagating in the \(x_1\) normal direction. When doing so, a system of equations can be written to describe the wave propagation as follows:
\[
\begin{align*}
\frac{\partial \rho}{\partial t} + d_1 + \frac{\partial m_2}{\partial x_2} + \frac{\partial m_3}{\partial x_3} &= 0 \\
\frac{\partial m_1}{\partial t} + U_1d_1 + \rho d_3 + \frac{\partial (m_1 U_2)}{\partial x_2} + \frac{\partial (m_1 U_3)}{\partial x_3} &= 0 \\
\frac{\partial m_2}{\partial t} + U_2d_1 + \rho d_4 + \frac{\partial (m_2 U_2)}{\partial x_2} + \frac{\partial (m_2 U_3)}{\partial x_3} + \frac{\partial P}{\partial x_2} &= 0 \\
\frac{\partial m_3}{\partial t} + U_3d_1 + \rho d_5 + \frac{\partial (m_3 U_2)}{\partial x_2} + \frac{\partial (m_3 U_3)}{\partial x_3} + \frac{\partial P}{\partial x_3} &= 0 \\
\frac{\partial \rho E}{\partial t} + \frac{1}{2} |V|^2d_1 + \frac{d_2}{(\gamma - 1)} + m_1d_3 + m_2d_4 + m_3d_5 + \frac{\partial [(\rho E + P) U_2]}{\partial x_2} + \frac{\partial [(\rho E + P) U_3]}{\partial x_3} &= 0
\end{align*}
\] (6.162)

Where \( m_1 = \rho U_1 \), \( m_2 = \rho U_2 \) and \( m_3 = \rho U_3 \) and \( U_1, U_2 \) and \( U_3 \) are the velocity components in the coordinate system \((x_1, x_2, x_3)\). The equations above are solved on non-reflecting boundaries, along with the interior governing flow equations, using similar time stepping algorithms to obtain the values of the primitive flow variables \((P, u, v, w, T)\).

---

**Important**

Note that a transformation between the local orthogonal coordinate system \((x_1, x_2, x_3)\) and the global Cartesian system \((X, Y, Z)\) must be defined on each face on the boundary to obtain the velocity components \((u, v, w)\) in a global Cartesian system.
The $d_i$ terms in the transformed Euler equations contain the outgoing and incoming characteristic wave amplitudes, $L_{ji}$, and are defined as follows:

$$d_1 = \frac{1}{c^2} \left[ L_2 + \frac{1}{2} (L_5 + L_1) \right]$$
$$d_2 = \frac{1}{2} (L_5 + L_1)$$
$$d_3 = \frac{1}{2pc} (L_5 - L_1)$$
$$d_4 = L_3$$
$$d_5 = L_4$$

From characteristic analyses, the wave amplitudes, $L_{ji}$, are given by:
The outgoing and incoming characteristic waves are associated with the characteristic velocities of the system (i.e. eigenvalues), $\lambda_j$, as seen in Figure 6.60: Waves Leaving and Entering a Boundary Face on Inflow and Outflow Boundaries. The Wave Amplitudes are Shown with the Associated Eigenvalues for a Subsonic Flow Condition (p. 366). These eigenvalues are given by:

$$
\begin{align*}
\lambda_1 &= U_1 - c \\
\lambda_2 &= \lambda_3 = \lambda_4 = U_1 \\
\lambda_5 &= U_1 + c
\end{align*}
$$

For subsonic flow leaving a boundary, four waves leave the domain (associated with positive eigenvalues $\lambda_1$, $\lambda_2$, $\lambda_3$, and $\lambda_4$) and one enters the domain (associated with negative eigenvalue $\lambda_5$). For subsonic
flow entering a boundary, four waves enter the domain (associated with the negative eigenvalues \(\lambda_1, \lambda_2, \lambda_3, \lambda_4\)) and one leaves the domain (associated with a positive eigenvalue \(\lambda_5\)).

To solve Equation 6.162 (p. 364) on a boundary, the amplitude of the incoming and outgoing waves must be first determined. The amplitude of outgoing waves are computed from Equation 6.164 (p. 366) by using extrapolated values of flow derivatives \(\frac{\partial P}{\partial x_1}, \frac{\partial \rho}{\partial x_1}, \frac{\partial U_1}{\partial x_1}, \frac{\partial U_2}{\partial x_1}, \text{ and } \frac{\partial U_3}{\partial x_1}\) from inside the domain.

The amplitude of the incoming waves are computed as follows. The amplitude of waves \(L_2 L_4\) for tangential velocity components, is set to zero. The amplitude of the incoming pressure and entropy waves are computed from the Linear Relaxation Method (LRM) of Poinsot\footnote{Release 15.0 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.} (p. 2561)\footnote{Release 15.0 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.}. The LRM method sets the value of the incoming wave amplitude to be proportional to the differences between the local primitive variable on a boundary face and the imposed boundary value. The expression for the amplitudes depends on the boundary type as shown below:

1. **Pressure Outlet**

   \[ L_1 = K \left( P - P_{\text{exit}} \right) \]  

   where \(P_{\text{exit}}\) is the imposed pressure at the exit boundary, \(K\) is the relaxation factor, and \(P\) is the local pressure value at the boundary.

   In general, the desirable average pressure on a non-reflecting boundary can be either relaxed toward a pressure value at infinity or enforced to be equivalent to some desired pressure at the exit of the boundary.

   In the case of a backflow, the pressure-based solver has two options for specifying pressure at the boundary; static pressure or total pressure. If the static pressure option is selected, the pressure at infinity is equal to the pressure defined on the boundary panel. If the total pressure option is selected, the pressure at infinity is computed from the total pressure value from the panel. In the density-based solver, pressure at the boundary is treated as total pressure for a backflow case.

   If you want the average pressure at the boundary to relax toward \(P\) at infinity (that is \(P_{\text{exit}} = P_\infty\)), the suggested \(K\) factor is given by:

   \[ K = \sigma_1 \left(1 - M_{\text{max}}^2\right) \frac{c}{h} \]  

   where \(c\) is the acoustic speed, \(h\) is the domain size, \(M_{\text{max}}\) is the maximum Mach number in the domain, and \(\sigma_1\) is the under-relaxation factor (default value is 0.15). On the other hand, if the desired average pressure at the boundary is to approach a specific imposed value at the boundary, then the \(K\) factor is given by:

   \[ K = \sigma_2 c \]  

   where the default value for \(\sigma_2\) is 5.0

   **Important**

   The desired average pressure option is only available for the density-based solver.

2. **Pressure Inlet:**
\[ L_1 = K (P - P_{\text{exit}}) \]
\[ L_2 = K \left[ c^2 \left( \rho - \rho_{\text{exit}} \right) - (P - P_{\text{exit}}) \right] \] (6.169)

where the imposed pressure, \( P_{\text{exit}} \), and density, \( \rho_{\text{exit}} \), are computed from the specified total pressure and total temperature.

3. **Mass Flux Boundary:**
\[ L_1 = -Kpc \left( U_1 - U_{1,\text{exit}} \right) \]
\[ L_2 = Kc^2 \left( \rho - \rho_{\text{exit}} \right) \] (6.170)

where the imposed exit velocity and density are computed from specific mass flux and total temperature.

4. **Velocity Inlet:**
\[ L_1 = -Kpc \left( U_1 - U_{1,\text{exit}} \right) \]
\[ L_2 = Kc^2 \left( \rho - \rho_{\text{exit}} \right) \] (6.171)

where the imposed velocity, \( U_{1,\text{exit}} \), is specified at the boundary and the imposed density is computed from the specified boundary temperature and extrapolated pressure.

### 6.4.2.4. Using General Non-Reflecting Boundary Conditions

The general NRBC is available for use in the **Pressure Outlet** dialog box when either the density-based (with ideal gas law) or pressure-based solvers are activated to solve for compressible flows. The general NRBC is available for use in the **Pressure Inlet**, **Mass Flux** and **Velocity Inlet** dialog boxes when the pressure-based solver is activated to solve for compressible flows.

The example below shows you how to activate the general NRBC for a **Pressure Outlet** case. Similarly, you can active general NRBC for **Pressure Inlet**, **Mass Flux** and **Velocity Inlet** cases for compressible flows with the pressure-based solver.

1. Select **pressure-outlet** from the **Boundary Conditions** task page and click the **Edit...** button.
2. In the **Pressure Outlet** dialog box, enable the **Non-Reflecting Boundary** option.
3. For density-based solver, select one of the two **Exit Pressure Specification** options: **Pressure at Infinity** or **Average Boundary Pressure**. The pressure-based solver uses **Pressure at Infinity** option and **Exit Pressure Specification** is not shown.
Figure 6.61: The Pressure Outlet Dialog Box With the Non-Reflecting Boundary Enabled

- **Pressure at Infinity** boundary is typically used in unsteady calculations or when the exit pressure value is imposed at infinity. The boundary is designed so that the pressure at the boundary relaxes toward the imposed pressure at infinity. The speed at which this relaxation takes place is controlled by the parameter, \( \sigma \), which can be adjusted in the TUI:

  ```text
  define \rightarrow boundary-conditions \rightarrow non-reflecting-bc \rightarrow general-nrbc \rightarrow set
  ```

  In the set/ submenu, you can set the \( \sigma \) value. The default value for \( \sigma \) is 0.15.

- **Average Boundary Pressure** specification is usually used in steady-state calculations when you want to force the average pressure on the boundary to approach the exit pressure value. The matching of average exit pressure to the imposed average pressure is controlled by the parameter \( \sigma_2 \) which can be adjusted in the TUI:

  ```text
  define \rightarrow boundary-conditions \rightarrow non-reflecting-bc \rightarrow general-nrbc \rightarrow set
  ```

  In the set/ submenu, you can set the \( \sigma_2 \) value. The default value for \( \sigma_2 \) is 5.0.

Activation for the general NRBC for a flow inlet boundary box is similar to the Pressure Outlet example above.

**Important**

There is no guarantee that the \( \sigma_2 \) value of 5.0 will force the average boundary pressure to match the specified exit pressure in all flow situations. In the case where the desired average boundary pressure has not been achieved, you can intervene to adjust the \( \sigma_2 \) value so that the desired average pressure on the boundary is approached.
4. For the pressure-based solver, you can select one of two Backflow Pressure Specification options: Static Pressure or Total Pressure. For the density-based solver, the Backflow Pressure Specification is not shown and Total Pressure option is used by default.

**Important**

For the pressure-based solver, you should choose Direction Vector or From Neighboring Cell as the Backflow Direction Specification Method if the flow is tangential to the boundary. You should not select the Normal to the Boundary option for Backflow Direction Specification Method in this case because the face velocity components for this case will be computed from flux as zero during initialization. This initialization will cause the solver convergence to fail.

Usually, the solver can operate at higher CFL values without the NRBCs being turned on. Therefore, the best practice is to first achieve a good stable solution (not necessarily converged) before activating the non-reflecting boundary condition. In many flow situations, the CFL value must be reduced from the normal operation to keep the solution stable. This is particularly true with the density-based implicit solver since the boundary update is done in an explicit manner. A typical CFL value in the density-based implicit solver, with the NRBC activated, is 2.0 and 4.0 in the pressure-based solver.

### 6.5. User-Defined Fan Model

The user-defined fan model in ANSYS Fluent allows you to periodically regenerate a profile file that can be used to specify the characteristics of a fan, including pressure jump across the fan, and radial and swirling components of velocity generated by the fan.

For example, consider the calculation of the pressure jump across the fan. You can, through the standard interface, input a constant for the pressure jump, specify a polynomial that describes the pressure jump as a function of axial velocity through the fan, or use a profile file that describes the pressure jump as a function of the axial velocity or location at the fan face. If you use a profile file, the same profile will be used consistently throughout the course of the solution. Suppose, however, that you want to change the profile as the flow field develops. This would require a periodic update to the profile file itself, based upon some instructions that you supply. The user-defined fan model is designed to help you do this.

To use this model, you need to generate an executable that reads a fan profile file that is written by ANSYS Fluent, and writes out a modified one, which ANSYS Fluent will then read. The source code for this executable can be written in any programming language (Fortran or C, for example). Your program will be called and executed automatically, according to inputs that you supply through the standard interface.

Information about the user-defined fan model is provided in the following sections.

- **6.5.1. Steps for Using the User-Defined Fan Model**
- **6.5.2. Example of a User-Defined Fan**

#### 6.5.1. Steps for Using the User-Defined Fan Model

To make use of the user-defined fan model, follow the steps below.

1. In your model, identify one or more interior faces to represent one or more fan zones.
Boundary Conditions

2. Input the name of your executable and the instructions for reading and writing profile files in the User-Defined Fan Model Dialog Box (p. 2458).

Define → User-Defined → Fan Model...

3. Initialize the flow field and the profile files.

4. Enter the fan parameters using the standard Fan Dialog Box (p. 2110) (opened from the Boundary Conditions Task Page (p. 2102)).

5. Perform the calculation.

6.5.2. Example of a User-Defined Fan

Usage of the user-defined fan model is best demonstrated by an example. With this in mind, consider the domain shown in Figure 6.62: The Inlet, Fan, and Pressure Outlet Zones for a Circular Fan Operating in a Cylindrical Domain (p. 371). An inlet supplies air at 10 m/s to a cylindrical region, 1.25 m long and 0.2 m in diameter, surrounded by a symmetry boundary. At the center of the flow domain is a circular fan. A pressure outlet boundary is at the downstream end.

Figure 6.62: The Inlet, Fan, and Pressure Outlet Zones for a Circular Fan Operating in a Cylindrical Domain

Solving this problem with the user-defined fan model will cause ANSYS Fluent to periodically write out a radial profile file with the current solution variables at the fan face. These variables (static pressure, pressure jump, axial, radial, and swirling (tangential) velocity components) will represent averaged quantities over annular sections of the fan. The sizes of the annular regions are determined by the size of the fan and the number of radial points to be used in the profiles.

Once the profile file is written, ANSYS Fluent will invoke an executable, which will perform the following tasks:
1. Read the profile file containing the current flow conditions at the fan.

2. Perform a calculation to compute new values for the pressure jump, radial velocity, and swirl velocity for the fan.

3. Write a new profile file that contains the results of these calculations.

ANSYS Fluent will then read the new profile file and continue with the calculation.

### 6.5.2.1. Setting the User-Defined Fan Parameters

Specification of the parameters for the user-defined fan begins in the User-Defined Fan Model Dialog Box (p. 2458) (Figure 6.63: The User-Defined Fan Model Dialog Box (p. 372)).

Define → User-Defined → Fan Model...

Figure 6.63: The User-Defined Fan Model Dialog Box

In this dialog box, you can select the fan zone(s) on which your executable will operate under **Fan Zones**. In this example, there is only one fan, *fan-8*. If you have multiple fan zones in a simulation, for which you have different profile specifications, you can select them all at this point. Your executable will be able to differentiate between the fan zones because the zone ID for each fan is included in the solution profile file. The executable will be invoked once for each zone, and separate profile files will be written for each.

The executable file will be called on to update the profile file periodically, based on the input for the **Iteration Update Interval**. An input of 10, as shown in the dialog box, means that the fan executable in this example will act every 10 iterations to modify the profile file.

The number of points in the profile file to be written by ANSYS Fluent is entered under **Output Profile Points**. This profile file can have the same or a different number of points as the one that is written by the external executable.
Finally, the name of the executable should be entered under **External Command Name**. In the current example, the name of the executable is `fantest`.

**Important**

If the executable is not located in your working directory, then you must type the complete path to the executable.

### 6.5.2.2. Sample User-Defined Fan Program

The executable file will be built from the Fortran program, `fantest.f`, which is shown below. You can obtain a copy of this subroutine and the two that it calls (to read and write profile files) by contacting your ANSYS Fluent technical support engineer.

```fortran
! This program is invoked at intervals by ANSYS Fluent to
! read a profile-format file that contains radially
! averaged data at a fan face, compute new pressure-jump
! and swirl-velocity components, and write a new profile
! file that will subsequently be read by ANSYS Fluent to
! update the fan conditions.
!
! Usage: fantest input_profile output_profile
!
integer npmax
parameter (npmax = 900)
integer inp         ! input: number of profile points
integer iptype      ! input: profile type (0=radial, 1=point)
real ir(npmax)      ! input: radial positions
real ip(npmax)      ! input: pressure
real idp(npmax)     ! input: pressure-jump
real iva(npmax)     ! input: axial velocity
real ivr(npmax)     ! input: radial velocity
real ivt(npmax)     ! input: tangential velocity
character*80 zoneid
!
integer rfanprof    ! function to read a profile file
integer status
!
status = rfanprof(npmax,zoneid,iptype,
inp,ir,ip,idp,iva,ivr,ivt)
if (status.ne.0) then
  write(*,*),'error reading input profile file'
else
  do 10 i = 1, inp
     idp(i) = 200.0 - 10.0*iva(i)
     ivt(i) = 20.0*ir(i)
     ivr(i) = 0.0
  10 continue
call wfanprof(6,zoneid,iptype,inp,ir,idp,ivr,ivt)
endif
stop
end
```

After the variable declarations, which have comments on the right, the subroutine `rfanprof` is called to read the profile file, and pass the current values of the relevant variables (as defined in the declaration list) to `fantest`. A loop is done on the number of points in the profile to compute new values for:

- The pressure jump across the fan, `idp`, which in this example is a function of the axial velocity, `iva`.
- The swirling or tangential velocity, `ivt`, which in this example is proportional to the radial position, `ir`.
- The radial velocity, `ivr`, which in this example is set to zero.
Cell Zone and Boundary Conditions
After the loop, a new profile is written by the subroutine wfanprof, shown below. (For more information on profile file formats, see Profile File Format (p. 378).)
subroutine wfanprof(unit,zoneid,ptype,n,r,dp,vr,vt)
c
c
c
c

writes an ANSYS Fluent profile file for input by the
user fan model
integer unit
! output unit number
character*80 zoneid
integer ptype
! profile type (0=radial, 1=point)
integer n
! number of points
real r(n)
! radial position
real dp(n)
! pressure jump
real vr(n)
! radial velocity
real vt(n)
! tangential velocity
character*6 typenam
if (ptype.eq.0) then
typenam = ’radial’
else
typenam = ’point’
endif
write(unit,*) ’((’, zoneid(1:index(zoneid,’\0’)-1), ’ ’,
$ typenam, n, ’)’
write(unit,*) ’(r’
write(unit,100) r
write(unit,*) ’)’
write(unit,*) ’(pressure-jump’
write(unit,100) dp
write(unit,*) ’)’
write(unit,*) ’(radial-velocity’
write(unit,100) vr
write(unit,*) ’)’
write(unit,*) ’(tangential-velocity’
write(unit,100) vt
write(unit,*) ’)’
100 format(5(e15.8,1x))
return
end

This subroutine will write a profile file in either radial or point format, based on your input for the integer
ptype. (See Profiles (p. 377) for more details on the types of profile files that are available.) The names
that you use for the various profiles are arbitrary. Once you have initialized the profile files, the names
you use in wfanprof will appear as profile names in the Fan Dialog Box (p. 2110).

6.5.2.3. Initializing the Flow Field and Profile Files
The next step in the setup of the user-defined fan is to initialize (create) the profile files that will be
used. To do this, first initialize the flow field with the Solution Initialization Task Page (p. 2249) (using the
velocity inlet conditions, for example), and then type the command (update-user-fans) in the
console window. (The parentheses are part of the command, and must be typed in.)
This will create the profile names that are given in the subroutine wfanprof.

6.5.2.4. Selecting the Profiles
Once the profile names have been established, you will need to visit the Fan Dialog Box (p. 2110) (Figure 6.64: The Fan Dialog Box (p. 375)) to complete the problem setup. (See Fan Boundary Conditions (p. 335)
for general information on using the Fan dialog box.)

374

Figure 6.64: The Fan Dialog Box

At this time, the **Fan Axis**, **Fan Origin**, and **Fan Hub Radius** can be entered, along with the choice of profiles for the calculation of pressure jump, tangential velocity, and radial velocity. With the profile options enabled, you can select the names of the profiles from the drop-down lists. In the dialog box above, the selected profiles are named **fan-8 pressure-jump**, **fan-8 tangential-velocity**, and **fan-8 radial-velocity**, corresponding to the names that were used in the subroutine `wfanprof`.

### 6.5.2.5. Performing the Calculation

The solution is now ready to run. As it begins to converge, the report in the console window shows that the profile files are being written and read every 10 iterations:

```
iter  continuity  x-velocity  y-velocity  z-velocity  k
1     1.0000e+00  1.0000e+00  1.0000e+00  1.0000e+00  1.0000e+00
```

The file **fan-8-out.prof** is written out by ANSYS Fluent and read by the executable `fantest`. It contains values for pressure, pressure jump, axial velocity, radial velocity, and tangential velocity at 20 radial locations at the site of the fan. The file **fan-8-in.prof** is generated by `fantest` and contains updated values for pressure jump and radial and tangential velocity only. It is therefore a smaller file...
than `fan-8-out.prof`. The prefix for these files takes its name from the fan zone with which the profiles are associated. An example of the profile file `fan-8-in.prof` is shown below. This represents the last profile file to be written by `fantest` during the convergence history.

```plaintext

```

### 6.5.2.6. Results

A plot of the transverse velocity components at the site of the fan is shown in Figure 6.65: Transverse Velocities at the Site of the Fan (p. 376). As expected, there is no radial component, and the tangential (swirling) component increases with radius.

**Figure 6.65: Transverse Velocities at the Site of the Fan**

As a final check on the result, an XY plot of the static pressure as a function of \( x \) position is shown (Figure 6.66: Static Pressure Jump Across the Fan (p. 377)). This XY plot is made on a line at \( y = 0.05 \) m, or at about half the radius of the duct. According to the input file shown above, the pressure jump at the site of the fan should be approximately 97.8 Pa/m. Examination of the figure supports this finding.
6.6. Profiles

Profiles can be boundary conditions, cell zone conditions, and initial conditions for discrete phases. ANSYS Fluent provides a very flexible profile definition mechanism. This feature allows you to use experimental data, data calculated by an external program, or data written from a previous solution using the Write Profile Dialog Box (p. 2101) (as described in Reading and Writing Profile Files (p. 54)) as the boundary condition for a variable.

Information about profiles is presented in the following subsections:

6.6.1. Profile Specification Types
6.6.2. Profile File Format
6.6.3. Using Profiles
6.6.4. Reorienting Profiles
6.6.5. Defining Transient Cell Zone and Boundary Conditions

6.6.1. Profile Specification Types

The following is a list of the six types of profiles that can be read into ANSYS Fluent, as well as information about the interpolation method employed by ANSYS Fluent for each type.

- Point profiles are specified by an unordered set of \( n \) points: \( (x_i, y_i, v_i) \) for 2D problems or \( (x_i, y_i, z_i, v_i) \) for 3D problems, where \( 1 \leq i \leq n \). Profiles written using the Write Profile dialog box and profiles of experimental data in random order are examples of point profiles.

ANSYS Fluent will interpolate the point cloud to obtain values at the boundary faces. The default interpolation method for the unstructured point data is zeroth order. In other words, for each cell face at the boundary, the solver uses the value from the profile file located closest to the cell. Therefore, to get an accurate specification of an inlet profile using the default interpolation method, your profile file should contain a sufficiently high point density. For information about other available interpolation methods for point profiles, see Using Profiles (p. 380).

Figure 6.66: Static Pressure Jump Across the Fan
• Line profiles are specified for 2D problems by an ordered set of \( n \) points: \((x_i,y_i,v_i)\), where \( 1 \leq i \leq n \). Zeroth-order interpolation is performed between the points. An example of a line profile is a profile of data obtained from an external program that calculates a boundary-layer profile.

• Mesh profiles are specified for 3D problems by an \( m \) by \( n \) mesh of points: \((x_{ij},y_{ij},z_{ij},v_{ij})\), where \( 1 \leq i \leq m \) and \( 1 \leq j \leq n \). Zeroth-order interpolation is performed between the points. Examples of mesh profiles are profiles of data from a structured mesh solution and experimental data in a regular array.

• Radial profiles are specified for 2D and 3D problems by an ordered set of \( n \) points: \((r_i,v_i)\), where \( 1 \leq i \leq n \). The data in a radial profile are a function of radius only. Linear interpolation is performed between the points, which must be sorted in ascending order of the \( r \) field. The axis for the cylindrical coordinate system is determined as follows:
  - For 2D problems, it is the \( z \)-direction vector through \((0,0)\).
  - For 2D axisymmetric problems, it is the \( x \)-direction vector through \((0,0)\).
  - For 3D problems involving a swirling fan, it is the fan axis defined in the Fan Dialog Box (p. 2110) (unless you are using local cylindrical coordinates at the boundary, as described below).
  - For 3D problems without a swirling fan, it is the rotation axis of the adjacent fluid zone, as defined in the Fluid Dialog Box (p. 2085) (unless you are using local cylindrical coordinates at the boundary, as described below).
  - For 3D problems in which you are using local cylindrical coordinates to specify conditions at the boundary, it is the axis of the specified local coordinate system.

• Axial profiles are specified for 3D problems by an ordered set of \( n \) points: \((z_i,v_i)\), where \( 1 \leq i \leq n \). The data in an axial profile are a function of the axial direction. Linear interpolation is performed between the points, which must be sorted in ascending order of the \( z \) field.

• Transient profiles are specified for 2D and 3D profiles by an ordered set of \( n \) points: \((t_i,v_{0,i},v_{1,i},v_{2,i},...)\). Linear interpolations are done between the points which must be sorted in ascending order of the \( t \) (time or crank angle) field. Examples of transient profiles are transient cell zone and boundary conditions (see Defining Transient Cell Zone and Boundary Conditions (p. 388)) and point properties for particle injections (see Point Properties for Transient Injections (p. 1188)).

### 6.6.2. Profile File Format

The format of the profile files is fairly simple. The file can contain an arbitrary number of profiles. Each profile consists of a header that specifies the profile name, profile type (point, line, mesh, radial, or axial), and number of defining points, and is followed by an arbitrary number of named “fields”. Some of these fields contain the coordinate points and the rest contain boundary data.

**Important**

All quantities, including coordinate values, must be specified in SI units because ANSYS Fluent does not perform unit conversion when reading profile files.
Parentheses are used to delimit profiles and the fields within the profiles. Any combination of tabs, spaces, and newlines can be used to separate elements.

**Important**

In the general format description below, “|” indicates that you should input only one of the items separated by |’s and “...” indicates a continuation of the list.

```
((profile1-name point|line|radial n)
 (field1-name a1 a2 ... an)
 (field2-name b1 b2 ... bn)
 ...
 (fieldf-name f1 f2 ... fn))

((profile2-name mesh m n)
 (field1-name a11 a12 ... a1n
  a21 a22 ... a2n
  ...
  am1 am2 ... amn)
 ...
 (fieldf-name f11 f12 ... f1n
  f21 f22 ... f2n
  ...
  fm1 fm2 ... fmn))
```

Profile names must have all lowercase letters (for example, `name`). Uppercase letters in profile names are not acceptable. Each profile of type `point`, `line`, and `mesh` must contain fields with names `x`, `y`, and, for 3D, `z`. Each profile of type `radial` must contain a field with name `r`. Each profile of type `axial` must contain a field with name `z`. The rest of the names are arbitrary, but must be valid Scheme symbols. For compatibility with old-style profile files, if the profile type is missing, `point` is assumed.

### 6.6.2.1. Example

A typical usage of a profile file is to specify the profile of the boundary layer at an inlet. For a compressible flow calculation, this will be done using profiles of total pressure, `k`, and `ε`. For an incompressible flow, it might be preferable to specify the inlet value of streamwise velocity, together with `k` and `ε`.

Below is an example of a profile file that does this:

```
{(turb-prof point 8)
 (x
  4.00000E+00  4.00000E+00  4.00000E+00  4.00000E+00
  4.00000E+00  4.00000E+00  4.00000E+00  4.00000E+00 )
 (y
  1.06443E-03  3.19485E-03  5.33020E-03  7.47418E-03

```

```
6.6.3. Using Profiles

The procedure for using a profile to define a particular cell zone or boundary condition is outlined below.

1. Create a file that contains the desired profile, following the format described in Profile File Format (p. 378).

2. Read the profile using the Read... button in the Profiles Dialog Box (p. 2098) (Figure 6.67: The Profiles Dialog Box (p. 381))
   or the File/Read/Profile... menu item.

   - **Cell Zone Conditions → Profiles...**
   - **Boundary Conditions → Profiles...**
   - **File → Read → Profile...**

   Note that if you use the Profiles dialog box to read a file, and a profile in the file has the same name as an existing profile, the old profile will be overwritten.

3. If it is a point profile, you can choose the method of interpolation using the Profiles dialog box (Figure 6.67: The Profiles Dialog Box (p. 381)):
   - **Cell Zone Conditions → Profiles...**
   - **Boundary Conditions → Profiles...**

   Select the point profile in the Profile selection list. Then select one of the three choices in the Interpolation Method list and click the Apply button. The three choices include:

   - **Constant**
     This method is zeroth-order interpolation. For each cell face at the boundary, the solver uses the value from the profile file located closest to the cell. Therefore, the accuracy of the interpolated profile will be affected by the density of the data points in your profile file. This is the default interpolation method for point profiles.

   - **Inverse Distance**
     This method assigns a value to each cell face at the boundary based on weighted contributions from the values in the profile file. The weighting factor is inversely proportional to the distance between the profile point and the cell face center.

   - **Least Squares**
     This method assigns values to the cell faces at the boundary through a first-order interpolation method that tries to minimizes the sum of the squares of the offsets (residuals) between the profile data points and the cell face centers. The least squares solution is found using Singular Value Decomposition (SVD).
For information about the interpolation methods employed for other profile types (that is, line, mesh, radial, or axial profiles), see Profile Specification Types (p. 377).

4. In the boundary conditions dialog boxes (for example, the Velocity Inlet and Pressure Inlet dialog boxes), the fields defined in the profile file (and those defined in any other profile file that you have read in) will appear in the drop-down list to the right of or below each parameter for which profile specification is allowed. To use a particular profile, select it in the appropriate list.

5. Initialize the solution to interpolate the profile.

---

**Note**

You can use a profile file or the DEFINE_PROFILE user-defined function to specify volumetric source terms. If you specify the source terms with a profile, you will not have access to the central coefficient of the equations solved in order to linearize the source term. You will need to use a user-defined function to do this.

For more information on UDFs, refer to the UDF Manual.

### 6.6.3.1. Checking and Deleting Profiles

Each profile file contains one or more profiles, and each profile has one or more fields defined in it. Once you have read in a profile file, you can check which fields are defined in each profile, and you can also delete a particular profile. These tasks are accomplished in the Profiles Dialog Box (p. 2098) (Figure 6.67: The Profiles Dialog Box (p. 381)).

- Cell Zone Conditions ➔ Profiles...
- Boundary Conditions ➔ Profiles...

**Figure 6.67: The Profiles Dialog Box**

![Profiles Dialog Box](image)

To check which fields are defined in a particular profile, select the profile name in the Profile list. The available fields in that file will be displayed in the Fields list. In Figure 6.67: The Profiles Dialog Box (p. 381), the profile fields from the profile file of Example (p. 379) are shown.
To delete a profile, select it in the **Profile** list and click the **Delete** button. When a profile is deleted, all fields defined in it will be removed from the **Fields** list.

**Important**

If you are deleting an existing profile to replace it with a new profile, use the following procedure:

1. Delete the existing profile.
2. Change the parameters defined by the existing profile to **Constant**.
3. Read the new profile and apply as desired.

### 6.6.3.2. Viewing Profile Data

The **Plots** task page options allow you to generate XY plots of data related to profiles. You can plot the original data points from the profile file you have read into ANSYS Fluent, or you can plot the values assigned to the cell faces on the boundary after the profile file has been interpolated. See **XY Plots of Profiles** (p. 1703) for the steps to generate these plots.

You have the additional option of viewing the parameters) using the **Plot** or the **Contours** options. Note that these display options do not allow you to plot the actual values of the cell faces (as is done with the **Interpolated Data** option), because they interpolate the values stored in the adjacent cells.

To view the boundary condition parameters you must first read in the profile, save a boundary condition with a profile field selected as a parameter, and initialize the flow solution. Then you can view the surface data as follows:

- For 2D calculations, open the **Solution XY Plot** dialog box. Select the appropriate boundary zone in the **Surfaces** list, the variable of interest in the **Y Axis Function** drop-down list, and the desired **Plot Direction**. Ensure that the **Node Values** check button is turned on, and then click **Plot**. You should then see the profile plotted. If the data plotted does not agree with your specified profile, this means that there is an error in the profile file.

- For 3D calculations, use the **Contours** dialog box to display contours on the appropriate boundary zone surface. The **Node Values** check button must be turned on in order for you to view the profile data. If the data shown in the contour plot does not agree with your specified profile, this means that there is an error in the profile file.

### 6.6.3.3. Example

For the example given in **Example** (p. 379), the profiles are used for inlet values of \( x \) velocity, turbulent kinetic energy, and turbulent kinetic energy dissipation rate, as illustrated in **Figure 6.68: Example of Using Profiles as Boundary Conditions** (p. 383). (The \( y \) velocity is set to a constant value of zero, since it is assumed negligible. However, a profile of \( y \) velocity could also be used.)
6.6.4. Reorienting Profiles

For 3D cases only, ANSYS Fluent allows you to change the orientation of an existing profile so that it can be used at a boundary positioned arbitrarily in space. This allows you, for example, to take experimental data for an inlet with one orientation and apply it to an inlet in your model that has a different spatial orientation. Note that ANSYS Fluent assumes that the profile and the boundary are planar.

6.6.4.1. Steps for Changing the Profile Orientation

The procedure for orienting the profile data in the principal directions of a boundary is outlined below:

1. Define and read the profile as described in Using Profiles (p. 380).

2. In the Profiles Dialog Box (p. 2098), select the profile in the Profile list, and then click the Orient... button. This will open the Orient Profile Dialog Box (p. 2100) (Figure 6.69: The Orient Profile Dialog Box (p. 384)).
3. In the **Orient Profile** dialog box, enter the name of the new profile you want to create in the **New Profile** box.

4. Specify the number of fields you want to create using the up/down arrows next to the **New Fields** box. The number of new fields is equal to the number of vectors and scalars to be defined plus 1 (for the coordinates).

5. Define the coordinate field.
   
   a. Enter the names of the three coordinates \((x, y, z)\) in the first row under **New Field Names**.

   **Important**

   Ensure that the coordinates are named \(x, y, \) and \(z\) only. Do not use any other names or upper case letters in this field.

   b. Select the appropriate local coordinate fields for \(x, y, \) and \(z\) from the drop-down lists under **Compute From...**. (A selection of 0 indicates that the coordinate does not exist in the original profile; that is, the original profile was defined in 2D.)

6. Define the vector fields in the new profile.
a. Enter the names of the 3 components in the directions of the coordinate axes of the boundary under **New Field Names**.

**Important**

Do not use upper case letters in these fields.

b. Select the names of the 3 components of the vector in the local $x$, $y$, and $z$ directions of the profile from the drop-down lists under **Compute From**...

7. Define the scalar fields in the new profile.

a. Enter the name of the scalar in the first column under **New Field Names**.

**Important**

Do not use upper case letters in these fields.

b. Click the button under **Treat as Scalar Quantity** in the same row.

c. Select the name of the scalar in the corresponding drop-down list under **Compute From**....

8. Under **Orient To**..., specify the rotational matrix $RM$ under the **Rotation Matrix [RM]**. The rotational matrix used here is based on Euler angles ($\gamma$, $\beta$, and $\alpha$) that define an orthogonal system $x' y' z'$ as the result of the three successive rotations from the original system $xyz$. In other words,

$$
\begin{bmatrix}
  x' \\
  y' \\
  z'
\end{bmatrix} = [RM] \begin{bmatrix} x \\ y \\ z \end{bmatrix}
$$

(6.172)

$$
RM = [C][B][A]
$$

(6.173)

where $C$, $B$, and $A$ are the successive rotations around the $z$, $y$, and $x$ axes, respectively.

Rotation around the $z$ axis:

$$
C = \begin{bmatrix}
\cos \gamma & -\sin \gamma & 0 \\
\sin \gamma & \cos \gamma & 0 \\
0 & 0 & 1
\end{bmatrix}
$$

(6.174)

Rotation around the $y$ axis:

$$
B = \begin{bmatrix}
\cos \beta & 0 & \sin \beta \\
0 & 1 & 0 \\
-\sin \beta & 0 & \cos \beta
\end{bmatrix}
$$

(6.175)

Rotation around the $x$ axis:
$A = \begin{bmatrix}
1 & 0 & 0 \\
0 & \cos \alpha & -\sin \alpha \\
0 & \sin \alpha & \cos \alpha
\end{bmatrix}$

(6.176)

9. Under **Orient To...**, specify the **Direction Vector**. The **Direction Vector** is the vector that translates a profile to the new position, and is defined between the centers of the profile fields.

---

**Important**

Note that depending on your case, it may be necessary to perform only a rotation, only a translation, or a combination of a translation and a rotation.

---

10. Click the **Create** button in the **Orient Profile** dialog box, and your new profile will be created. Its name, which you entered in the **New Profile** box, will now appear in the **Profiles** dialog box and will be available for use at the desired boundary.

**6.6.4.2. Profile Orienting Example**

Consider the domain with a square inlet and outlet, shown in **Figure 6.70: Scalar Profile at the Outlet** (p. 386). A scalar profile at the outlet is written out to a profile file. The purpose of this example is to impose this outlet profile on the inlet boundary via a $90^\circ$ rotation about the $x$ axis. However, the rotation will locate the profile away from the inlet boundary. To align the profile to the inlet boundary, a translation via a directional vector must be performed.

**Figure 6.70: Scalar Profile at the Outlet**
The problem is shown schematically in Figure 6.71: Problem Specification (p. 388). $\Phi_{out}$ is the scalar profile of the outlet. $\Phi_{out}'$ is the image of the $\Phi_{out}$ rotated 90° around the $x$ axis. In this example, since $\gamma = \beta = 0$, then $C = B = I$, where $I$ is the identity matrix, and the rotation matrix is

$$RM = [C][B][A] = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos 90° & -\sin 90° \\ 0 & \sin 90° & \cos 90° \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{bmatrix} \quad (6.177)$$

To overlay the outlet profile on the inlet boundary, a translation will be performed. The directional vector is the vector that translates $\Phi_{out}'$ to $\Phi_{in}$. In this example, the directional vector is $(0, 15, -10)^T$. The appropriate inputs for the Orient Profile dialog box are shown in Figure 6.69: The Orient Profile Dialog Box (p. 384).

Note that if the profile being imposed on the inlet boundary was due to a rotation of -90° about the $x$ axis, then the rotational matrix $RM$ must be found for $\gamma = \beta = 0$ and $\alpha = -90°$, and a new directional vector must be found to align the profile to the boundary.
6.6.5. Defining Transient Cell Zone and Boundary Conditions

There are two ways you can specify transient cell zone and boundary conditions:

- transient profile with a format similar to the standard profiles described in Profiles (p. 377)
- transient profile in a tabular format

**Important**

For both methods, the cell zone or boundary condition will vary only in time; it must be spatially uniform. However, if the in-cylinder model is activated (In-Cylinder Settings (p. 621)), then you have the option to use the crank angle instead of time. Crank angles can be included in transient tables as well as transient profiles, in a similar fashion to time. Examples of transient profiles and transient tables in crank angle can be found in the sections that follow.
For information about boundary profiles, refer to Reading and Writing Profile Files (p. 54).

6.6.5.1. Standard Transient Profiles

The format of the standard transient profile file (based on the profiles described in Profiles (p. 377)) is

```((profile-name transient n periodic?)
 (field_name-1 a1 a2 a3 .... an)
 (field_name-2 b1 b2 b3 .... bn)
 .
 .
 .
 (field_name-r r1 r2 r3 .... rn))
```

The profile name as well as the field names have to be shorter than 64 characters. One of the field_names should be used for the time field, and the time field section must be in ascending order. n is the number of entries per field. The periodic? entry indicates whether or not the profile is time-periodic. Set it to 1 for a time-periodic profile, or 0 if the profile is not time-periodic.

An example is shown below:

```((sampleprofile transient 3 0)
 (time
  1
  2
  3
 )
 (u
  10
  20
  30
 )
 )
```

This example demonstrates the use of crank angle in a transient profile

```((example transient 3 1)
 (angle
  0.000000e+00 1.800000e+02 3.600000e+02
 )
 (temperature
  3.000000e+02 5.000000e+02 3.000000e+02
 )
 )
```

**Important**

All quantities, including coordinate values, must be specified in SI units because ANSYS Fluent does not perform unit conversion when reading profile files. Also, profile names must have all lowercase letters (for example, name). Uppercase letters in profile names are not acceptable.

You can read this file into ANSYS Fluent using the Profiles Dialog Box (p. 2098) or the File/Read/Profile... menu item.

- Cell Zone Conditions ➔ Profiles...
- Boundary Conditions ➔ Profiles...

File ➔ Read ➔ Profile...
6.6.5.2. Tabular Transient Profiles

The format of the tabular transient profile file is

```
profile-name n_field n_data periodic?
field-name-1 field-name-2 field-name-3 .... field-name-n_field
v-1-1  v-2-1... ... ... ... v-n_field-1
v-1-2  v-2-2... ... ... ... v-n_field-2
```

The first field name (for example field-name-1) should be used for the time field, and the time field section, which represents the flow time, must be in ascending order. The periodic? entry indicates whether or not the profile is time-periodic. Set it to 1 for a time-periodic profile, or 0 if the profile is not time-periodic.

An example is shown below:

```
sampletabprofile 2 3 0
time u
1 10
2 20
3 30
```

This file defines the same transient profile as the standard profile example above.

If the periodicity is set to 1, then n_data must be the number that closes one period.

An example is shown below:

```
periodtabprofile 2 4 1
time u
0 10
1 20
2 30
3 10
```

The following example uses crank angle instead of time:

```
example 2 3 1
angle temperature
0  300
180 500
360 300
```

**Important**

All quantities, including coordinate values, must be specified in SI units because ANSYS Fluent does not perform unit conversion when reading profile files. Also, profile names must have all lowercase letters (for example, name). Uppercase letters in profile names are not acceptable. When choosing the field names, spaces or parentheses should not be included.

You can read this file into ANSYS Fluent using the `read-transient-table` text command.

```
file → read-transient-table
```

See Using Profiles (p. 380) for details.
After reading the table into ANSYS Fluent, the profile will be listed in the Profiles Dialog Box (p. 2098) and can be used in the same way as a boundary profile. See Using Profiles (p. 380) for details.

### 6.7. Coupling Boundary Conditions with GT-Power

GT-Power users can define time-dependent boundary conditions in ANSYS Fluent based on information from GT-Power. During the ANSYS Fluent simulation, ANSYS Fluent and GT-Power are coupled together and information about the boundary conditions at each time step is transferred between them.

#### 6.7.1. Requirements and Restrictions

Note the following requirements and restrictions for the GT-Power coupling:

- The flow must be unsteady.
- The compressible ideal gas law must be used for density.
- Each boundary zone for which you plan to define conditions using GT-Power must be a flow boundary of one of the following types:
  - velocity inlet
  - mass flow inlet
  - pressure inlet
  - pressure outlet

Also, a maximum of 20 boundary zones can be coupled to GT-Power.

- If a mass flow inlet or pressure inlet is coupled to GT-Power, you must select Normal to Boundary as the Direction Specification Method in the Mass-Flow Inlet or Pressure Inlet dialog box. For a velocity inlet, you must select Magnitude, Normal to Boundary as the Velocity Specification Method in the Velocity Inlet dialog box.
- The mass flow specification method in the Mass-Flow Inlet boundary has to always be Mass Flux and not Mass Flow Rate when coupling with GT-Power.
- Boundary conditions for the following variables can be obtained from GT-Power:
  - velocity
  - temperature
  - pressure
  - density
  - species mass fractions
  - $k$ and $\varepsilon$ (Note that it is recommended that you define these conditions in ANSYS Fluent yourself, rather than using the data provided by GT-Power, since the GT-Power values are based on a 1D model.)
• Make sure that the material properties you set in ANSYS Fluent are the same as those used in GT-Power, so that the boundary conditions will be valid for your coupled simulation.

• If your model includes species, make sure that the name of each species in GT-Power corresponds to the Chemical Formula for that species material in the Materials dialog box. Also, recall that ANSYS Fluent can handle a maximum of 50 species.

• You can install the GT-Power libraries in a directory other than the default location. If the GT-Power libraries are loaded into a non-default location, you need to set the following environment variables:
  - Fluent_GTIHOME: the GTI installation directory where GT-Power is installed
  - Fluent_GTIVERSION: the current version of the GTI installation

Important

GTI is not backwards compatible.

6.7.2. User Inputs

The procedure for setting up the GT-Power coupling in ANSYS Fluent is presented below.

1. Read in the mesh file and define the models, materials, and boundary zone types (but not the actual boundary conditions), noting the requirements and restrictions listed in Requirements and Restrictions (p. 391).

2. Specify the location of the GT-Power data and have ANSYS Fluent use them to generate user-defined functions for the relevant boundary conditions (using the 1D Simulation Library Dialog Box (p. 2459), shown in Figure 6.72: The 1D Simulation Library Dialog Box (p. 392)).

   Define → User-Defined → 1D Coupling...

Figure 6.72: The 1D Simulation Library Dialog Box

   a. Select GTpower in the 1D Library drop-down list.
   b. Specify the name of the GT-Power input file in the 1D Input File Name field.
   c. Click the Start button.

When you click Start, GT-Power will start up and ANSYS Fluent user-defined functions for each boundary in the input file will be generated.
3. Set boundary conditions for all zones. For flow boundaries for which you are using GT-Power data, select the appropriate UDFs as the conditions.

**Important**

Note that you must select the same UDF for all conditions at a particular boundary zone (as shown, for example, in Figure 6.73: Using GT-Power Data for Boundary Conditions (p. 393)); this UDF contains all of the conditions at that boundary.

**Figure 6.73: Using GT-Power Data for Boundary Conditions**

4. If you plan to continue the simulation at a later time, starting from the final data file of the current simulation, specify how often you want to have the case and data files saved automatically.

**Calculation Activities (Autosave Case/Data) → Edit...**

To use a GT-Power restart file to restart an ANSYS Fluent calculation, you must edit the GT-Power input data file. See the GT-Power User’s Guide for instructions.

5. Continue the problem setup and calculate a solution in the usual manner.

### 6.8. Coupling Boundary Conditions with WAVE

WAVE users can define time-dependent boundary conditions in ANSYS Fluent based on information from WAVE. During the ANSYS Fluent simulation, ANSYS Fluent and WAVE are coupled together and information about the boundary conditions at each time step is transferred between them.
6.8.1. Requirements and Restrictions

Note the following requirements and restrictions for the WAVE coupling:

- WAVE must be installed and licensed.

- There are always five species that must be modeled in ANSYS Fluent just as they are defined in WAVE (F1, F2, F3, F4, and F5). It is recommended that realistic material properties be assigned to each of the five species.

- The flow must be unsteady.

- The compressible ideal gas law must be used for density.

- Each boundary zone for which you plan to define conditions using WAVE must be a flow boundary of one of the following types:
  - velocity inlet
  - mass flow inlet
  - pressure inlet
  - pressure outlet

Also, a maximum of 20 boundary zones can be coupled to WAVE.

- If a mass flow inlet or pressure inlet is coupled to WAVE, you must select Normal to Boundary as the Direction Specification Method in the Mass-Flow Inlet or Pressure Inlet Dialog Box. For a velocity inlet, you must select Magnitude, Normal to Boundary as the Velocity Specification Method in the Velocity Inlet Dialog Box.

- Boundary conditions for the following variables can be obtained from WAVE:
  - velocity
  - temperature
  - pressure
  - density
  - species mass fractions
  - k and ε (Note that you are required to define these conditions in ANSYS Fluent yourself, since WAVE does not calculate them.)

- Make sure that the material properties you set in ANSYS Fluent are the same as those used in WAVE, so that the boundary conditions will be valid for your coupled simulation.

- If your model includes species, make sure that the name of each species in WAVE corresponds to the Chemical Formula for that species material in the Create/Edit Materials dialog box. Also, recall that ANSYS Fluent can handle a maximum of 50 species.
6.8.2. User Inputs

The procedure for setting up the WAVE coupling in ANSYS Fluent is presented below.

1. Read in the mesh file and define the models, materials, and boundary zone types.

2. Specify the location of the WAVE data and have ANSYS Fluent use them to generate user-defined functions for the relevant boundary conditions (using the 1D Simulation Library Dialog Box (p. 2459), shown in Figure 6.74: The 1D Simulation Library Dialog Box with WAVE Selected (p. 395)).

   **Define → User-Defined → 1D Coupling...**

   **Figure 6.74: The 1D Simulation Library Dialog Box with WAVE Selected**

   ![1D Simulation Library Dialog Box](image)

   a. Select WAVE in the **1D Library** drop-down list.

   b. Specify the name of the WAVE input file in the **1D Input File Name** field.

   c. Click the **Start** button.

   When you click **Start**, WAVE will start up and ANSYS Fluent user-defined functions for each boundary in the input file will be generated.

3. Set boundary conditions for all zones. For flow boundaries for which you are using WAVE data, select the appropriate UDFs as the conditions.

   **Important**

   Note that you must select the same UDF for all conditions at a particular boundary zone (as shown, for example, in Figure 6.75: Using WAVE Data for Boundary Conditions (p. 396)); this UDF contains all of the conditions at that boundary.
4. If you plan to continue the simulation at a later time, restarting from the final data file of the current simulation, you need to instruct both ANSYS Fluent and WAVE how often that you want to automatically save your data. You should instruct ANSYS Fluent to automatically save case and data files at specified intervals using the autosave feature.

**Calculation Activities (Autosave Case/Data) → Edit...**

In addition, you should instruct WAVE as to how often it should generate its own restart files. See the WAVE User’s Guide for instructions on this feature.

---

**Important**

To use the restart feature, the time interval for writing data files must be set to the same value in both ANSYS Fluent and WAVE. For example, if ANSYS Fluent has set the autosave feature to 100, then WAVE must also set the restart file write frequency to 100 as well.

---

5. Continue the problem setup and calculate a solution in the usual manner.
Chapter 7: Physical Properties

This chapter describes how to define materials, the physical equations used to compute material properties, and the methods you can use for each property input. Each property is described in detail in the following sections. If you are using one of the general multiphase models (VOF, mixture, or Eulerian), see Defining the Phases (p. 1250) for information about how to define the individual phases and their material properties.

7.1. Defining Materials
7.2. Defining Properties Using Temperature-Dependent Functions
7.3. Density
7.4. Viscosity
7.5. Thermal Conductivity
7.6. User-Defined Scalar (UDS) Diffusivity
7.7. Specific Heat Capacity
7.8. Radiation Properties
7.9. Mass Diffusion Coefficients
7.10. Standard State Enthalpies
7.11. Standard State Entropies
7.12. Unburnt Thermal Diffusivity
7.13. Kinetic Theory Parameters
7.14. Operating Pressure
7.15. Reference Pressure Location
7.16. Real Gas Models

7.1. Defining Materials

An important step in the setup of the model is to define the materials and their physical properties. Material properties are defined in the Materials Task Page (p. 2020), where you can enter values for the properties that are relevant to the problem scope you have defined in the Models Task Page (p. 1896). These properties may include the following:

• density and/or molecular weights
• viscosity
• heat capacity
• thermal conductivity
• UDS diffusion coefficients
• mass diffusion coefficients
• standard state enthalpies
• kinetic theory parameters
Properties may be temperature-dependent and/or composition-dependent, with temperature dependence based on a polynomial, piecewise-linear, or piecewise-polynomial function and individual component properties either defined by you or computed via kinetic theory.

The Materials Task Page (p. 2020) will show the properties that need to be defined for the active physical models. If any property you define requires the energy equation to be solved (for example, ideal gas law for density, temperature-dependent profile for viscosity), ANSYS Fluent will automatically activate the energy equation. Then you have to define the thermal boundary conditions and other parameters yourself.

For additional information, see the following sections:

- 7.1.1. Physical Properties for Solid Materials
- 7.1.2. Material Types and Databases
- 7.1.3. Using the Materials Task Page
- 7.1.4. Using a User-Defined Materials Database

### 7.1.1. Physical Properties for Solid Materials

For solid materials, only density, thermal conductivity, and heat capacity are defined. If you are modeling semi-transparent media, then radiation properties are also defined. You can specify a constant value, a temperature-dependent function, or a user-defined function for thermal conductivity; a constant value or temperature-dependent function for heat capacity; and a constant value for density.

If you are using the pressure-based solver, density and heat capacity for a solid material are not required unless you are modeling transient flow or moving solid zones. Heat capacity will appear in the list of solid properties for steady flows as well. The value will be used just for postprocessing enthalpy; not in the calculation.

### 7.1.2. Material Types and Databases

In ANSYS Fluent, you can define six types of materials: fluids, solids, mixtures, combusting-particles, droplet-particles, and inert-particles. Physical properties of fluids and solids are associated with named material; these materials are then assigned as boundary conditions for zones.

When you model species transport, define a mixture material, consisting of the various species involved in the problem. Properties will be defined for the mixture, as well as for the constituent species, which are fluid materials. The mixture material concept is discussed in detail in Mixture Materials (p. 887). Combusting-particles, droplet-particles, and inert-particles are available for the discrete-phase model, as described in The Concept of Discrete-Phase Materials (p. 1197).

ANSYS Fluent provides a built-in global database of approximately 675 predefined materials along with their properties and default values for each property. To define a material in the problem setup, you can copy materials from this global (site-wide) database and use the default properties or define new materials by editing their properties. The ANSYS Fluent materials database is located in the following file:

```
path /ansys_inc/v150/fluent/fluent15.0.0/cortex/lib/propdb.scm
```

where `path` is the directory in which you installed ANSYS Fluent.
In addition to using the ANSYS Fluent material database, you can also create your own database and materials, and use it to define the materials in your problem setup. See Using a User-Defined Materials Database (p. 404) for information about creating and using user-defined custom material databases.

**Important**

All the materials in your local materials list will be saved in the case file (when you write one). The materials specified by you will be available to you if you read this case file into a new solver session.

### 7.1.3. Using the Materials Task Page

The Materials Task Page (p. 2020) (Figure 7.1: The Materials Task Page (p. 399)) allows you to define the materials and their properties in your problem setup using either the Fluent Database or a User-Defined Database. It allows you to copy materials from a database, create new materials, and modify material properties.

These generic functions are described in this section. The inputs for temperature-dependent properties are explained in Defining Properties Using Temperature-Dependent Functions (p. 412). The specific inputs for each material property are discussed in the remaining sections of this chapter.

![Figure 7.1: The Materials Task Page](image-url)
By default, your local materials list will include a single fluid material (air) and a single solid material (aluminum). If the fluid involved in your problem is air, you can use the default properties for air or modify the properties. If the fluid in your problem is water, you can either copy water from the ANSYS Fluent database or create a new “water” material from scratch. If you copy water from the database, you can still make modifications to the properties of your local copy of water. The editing or creating of material properties is done in the Create/Edit Materials Dialog Box (p. 2022). To display the Create/Edit Materials Dialog Box (p. 2022), select the Create/Edit... button in the Materials Task Page (p. 2020). See the following sections for detailed information on how to change material properties.

Mixture materials will not exist in your local list unless you have enabled species transport (see Modeling Species Transport and Finite-Rate Chemistry (p. 885)). Similarly, inert, droplet, and combusting particle materials will not be available unless you have created a discrete phase injection of these particle types (see Modeling Discrete Phase (p. 1131)). When a mixture material is copied from the database, all of its constituent fluid materials (species) will automatically be copied over as well.

### 7.1.3.1. Modifying Properties of an Existing Material

Probably, the most common operation you will perform in the Create/Edit Materials Dialog Box (p. 2022) is the modification of properties for an existing material. The steps for this procedure are as follows:

1. Select the material you want to modify and the Create/Edit... button in the Materials Task Page (p. 2020).
2. In the Create/Edit Materials Dialog Box (p. 2022) select the type of material (fluid, solid, etc.) in the Material Type drop-down list.
3. Choose the material for which you want to modify properties, in the Fluent Fluid Materials drop-down list, Fluent Solid Materials list, or other similarly named list. The name of the list will be the same as the material type you selected in the previous step.
4. Make the required changes to the properties listed in the Properties section of the dialog box. You can use the scroll bar to the right of the Properties section to scroll through the listed items.
5. Click the Change/Create button to change the properties of the selected material to your new property settings.

To change the properties of an additional material, repeat the process described above. Click the Change/Create button after making changes to the properties for each material.

### 7.1.3.2. Renaming an Existing Material

Each material is identified by a name and a chemical formula (if one exists). You can change the name of a material, but not its chemical formula (unless you are creating a new material). The procedure for renaming a material is as follows:

1. Select the material you want to rename and click the Create/Edit... button in the Materials Task Page (p. 2020).
2. In the Create/Edit Materials Dialog Box (p. 2022), choose the material for which you want to modify properties, in the Fluent Fluid Materials list, Fluent Solid Materials list, or other similarly named list. The name of the list will be the same as the material type you selected in the previous step.
3. Enter the new name in the **Name** field at the top of the Create/Edit Materials Dialog Box (p. 2022).

**Important**

The maximum character length you can enter in the **Name** field is 29. If you enter a material name that is more than 29 characters long, ANSYS Fluent will print an error message in the console window.

4. Click the **Change/Create** button.

A **Question Dialog Box** (p. 15) will appear, asking you if the original material should be overwritten.

If you are renaming the original material, click **Yes** to overwrite it. If you were creating a new material, click **No** to retain the original material.

To rename another material, repeat the process described above. Click the **Change/Create** button after renaming each material.

### 7.1.3.3. Copying Materials from the ANSYS Fluent Database

The global (site-wide) materials database contains many commonly used fluid, solid, and mixture materials, with property data from several different sources [56] (p. 2560), [82] (p. 2561), [115] (p. 2563), [38] (p. 2559).

To use one of these materials in your problem, copy it from the ANSYS Fluent database to your local materials list. The procedure for copying a material is as follows:

1. Click the **Fluent Database...** button in the Create/Edit Materials Dialog Box (p. 2022) to open the Fluent Database Materials Dialog Box (p. 2030) (Figure 7.2: Fluent Database Materials Dialog Box (p. 402)).
2. Select the type of material (fluid, solid, etc.) in the **Material Type** drop-down list.

3. In the **Fluent Fluid Materials** list, **Fluent Solid Materials** list, or other similarly named list, choose the materials you want to copy by clicking on them. The properties of the selected material will be displayed in the **Properties** area.

4. To check the material properties, use the scroll bar to the right of the **Properties** area to scroll through the listed items. For some properties, temperature-dependent functions are available in addition to the constant values. Select one of the function types in the drop-down list to the right of the property and the relevant parameters will be displayed. You cannot edit these values, but the dialog boxes in which they are displayed function in the same way as those used for setting temperature-dependent property functions ([Defining Properties Using Temperature-Dependent Functions](p. 412)).

The inactive buttons in the **Fluent Database Materials Dialog Box** (p. 2030) are operations that are applicable only for a user-defined database. These operations will be available when you click the **User-Defined Database...** button in the **Create/Edit Materials Dialog Box** (p. 2022).

5. Click **Copy**. The materials and their properties will be downloaded from the database into your local list, and your copy of properties will now be displayed in the **Materials Task Page** (p. 2020).
6. Close the Fluent Database Materials Dialog Box (p. 2030).

After copying a material from the database, you can modify its properties or change its name, as described earlier in this section. The original material in the database will not be affected by any changes made to your local copy of the material.

### 7.1.3.4. Creating a New Material

If the material you want to use is not available in the database, you can easily create a new material for the local list. This material will be available for use only for the current problem and will not be saved in the ANSYS Fluent database. The procedure for creating a new material is as follows:

1. Click the Create/Edit... button in the Materials Task Page (p. 2020).

2. Select the new material type (fluid, solid, etc.) in the Material Type drop-down list. It does not matter which material is selected in the Fluent Fluid Materials, Fluent Solid Materials, or other similarly named list.

3. Enter the new material name in the Name field.

   **Important**

   The maximum character length you can enter in the Name field is 29. If you enter a material name that is more than 29 characters long, ANSYS Fluent will print an error message in the console window.

4. Set the material's properties in the Properties area. If there are many properties listed, you may use the scroll bar to the right of the Properties area to scroll through the listed items.

5. Click the Change/Create button. A Question Dialog Box (p. 15) will appear, asking you if the original material should be overwritten.

   a. Click No to retain the original material and add your new material to the list. A dialog box will appear asking you to enter the chemical formula of your new material.

   b. Click OK, enter the formula if it is known. Else, leave the formula blank and click OK. Select the Change/Create button and answer the Question.

   The Materials Task Page (p. 2020) will be updated to show the new material name and chemical formula in the Fluent Fluid Materials list (or Fluent Solid Materials or other similarly named list).

### 7.1.3.5. Saving Materials and Properties

All the materials and properties in your local list are saved in the case file when it is written. If you read this case file into a new solver session, all of your materials and properties will be available for use in the new session.

### 7.1.3.6. Deleting a Material

If there are materials list that you no longer need, you can delete them:

1. Choose the material to be deleted in the Materials Task Page (p. 2020).
2. Click the **Delete** button at the bottom of the Materials Task Page (p. 2020).

You can also delete materials in the **Create/Edit Materials Dialog Box (p. 2022)**.

1. Select the material to be deleted and click the **Create/Edit...** button in the Materials Task Page (p. 2020).

2. In the Create/Edit Materials Dialog Box (p. 2022), select the type of material (**fluid**, **solid**, etc.) in the **Material Type** drop-down list.

3. Choose the material to be deleted in the **Fluent Fluid Materials** drop-down list, **Fluent Solid Materials** list, or other similarly named list. The list’s name will be the same as the material type you selected in the previous step.

4. Click the **Delete** button at the bottom of the Materials Task Page (p. 2020).

   Deleting materials from your local list will have no effect on the materials contained in the global database.

### 7.1.3.7. Changing the Order of the Materials List

By default, the materials in your local list and those in the database are listed alphabetically by name (for example, **air**, **atomic-oxygen (o)**, **carbon-dioxide (co2)**). If you prefer to list them alphabetically by chemical formula, select the **Chemical Formula** option under **Order Materials By**. The example materials listed, will now be in the order of: **air**, **co2 (carbon-dioxide)**, **o (atomic-oxygen)**. To change back to the alphabetical listing by name, choose the **Name** option under **Order Materials By**.

You may specify the ordering method separately for the Create/Edit Materials Dialog Box (p. 2022) and Fluent Database Materials Dialog Box (p. 2030). For example, you can order the database materials list by name. Each dialog box has its own **Order Materials By** options.

### 7.1.4. Using a User-Defined Materials Database

In addition to the Fluent Database Materials Dialog Box (p. 2030), you can also use or create a user-defined materials database using the User-Defined Database Materials Dialog Box (p. 2032). You can browse and do the following:

- select from existing user-defined databases
- copy materials from a user-defined database
- create a new database, create new materials
- add them to the user-defined database
- delete materials from the database
- copy materials from a case to a user-defined database
- view the database

The following sections will address each of these functionalities in detail.
7.1.4.1. Opening a User-Defined Database

In ANSYS Fluent, you can open databases of custom materials saved as .scm files and use them to define the materials in your problem setup. The material data must be prepared in a specific format as shown in the examples that follow.

Examples:

The prescribed format for saving material properties information is shown here for air and aluminum. These files can be created in a text editor and saved with a .scm extension.

```plaintext
((air
 fluid
 (chemical-formula . #f)
 (density (constant . 1.225))
 (premixed-combustion 1.225 300))
 (specific-heat (constant . 1006.43))
 (thermal-conductivity (constant . 0.0242))
 (viscosity (constant . 1.7894e-05)
 sutherland 1.7894e-05 273.11 110.56)
 (power-law 1.7894e-05 273.11 0.666))
 (molecular-weight (constant . 28.966))
)

(aluminum
 solid
 (chemical-formula . al)
 (density (constant . 2719))
 (specific-heat (constant . 871))
 (thermal-conductivity (constant . 202.4))
 (formation-entropy (constant . 164448.08))
)
```

To select a user-defined database, click the **User-Defined Database...** button in the Create/Edit Materials Dialog Box (p. 2022). This will open the Open Database Dialog Box (p. 2031).

**Figure 7.3: Open Database Dialog Box**

![Open Database Dialog Box](image)

Click the **Browse...** button, select the database in The Select File Dialog Box (p. 15) that opens and click **OK**. Click **OK** in the Open Database Dialog Box (p. 2031) to open the User-Defined Database Materials Dialog Box (p. 2032).

7.1.4.2. Viewing Materials in a User-Defined Database

When an existing user-defined database is opened, the materials present in the database are listed in the User-Defined Database Materials Dialog Box (p. 2032). You can select the material type in the Material Type drop-down list and the corresponding materials will appear in the User-Defined Fluid Materials, User-Defined Solid Materials or other similarly named list. The name of the list will be the same as the material type you selected.
The properties of the selected material will appear in the **Properties** section of the dialog box. This dialog box is similar to the Fluent Database Materials Dialog Box (p. 2030) in function and operation.

### 7.1.4.3. Copying Materials from a User-Defined Database

The procedure for copying a material from a custom database is as follows:

1. In the Create/Edit Materials Dialog Box (p. 2022), click the **User-Defined Database...** button and open the database from which you want to copy the material.

2. In the User-Defined Database Materials Dialog Box (p. 2032) of the selected database, select the type of material (**fluid**, **solid**, etc.) in the **Material Type** drop-down list.

3. In the **User-Defined Fluid Materials** list, **User-Defined Solid Materials** list, or other similarly named list (the list's name will be the same as the material type you selected in the previous step), choose the materials you want to copy by clicking on them. The properties are displayed in the **Properties** area.

4. If you want to check the material properties, use the scroll bar to the right of the **Properties** area to scroll through the listed items.

5. Click the **Copy** button. The selected materials and their properties will be copied from the database into your local list, and your copy of the properties will now be displayed in the Materials Task Page (p. 2020).
To copy all the materials from the database in one step, click the button (ispiel) next to User-Defined Materials title and click Copy.

If a material with the same name is already defined in the case, ANSYS Fluent will prompt you to enter a new name and formula in the New Material Name Dialog Box (p. 2035). Enter a new name and formula in the respective fields and click OK to make a local copy of the material.

**Figure 7.5: New Material Name Dialog Box**

6. Close the User-Defined Database Materials Dialog Box (p. 2032).

After copying a material from the database, you may modify its properties or change its name, as described earlier in Using the Materials Task Page (p. 399). The material in the database will not be affected by any changes you make to your local copy of the material.

**7.1.4.4. Copying Materials from the Case to a User-Defined Database**

The procedure for copying a material to a custom database is as follows:

1. In the Create/Edit Materials Dialog Box (p. 2022), click User-Defined Database....

2. In the Open Database Dialog Box (p. 2031), select the database to which you want to copy the material. If you want to create a new database, enter the name of the new database in the Database Name field and click OK. A Question Dialog Box (p. 15) will ask you to confirm if you want to create a new file. Click Yes to confirm.

3. In the User-Defined Database Materials Dialog Box (p. 2032), click Copy Materials From Case..... This will open the Copy Case Material Dialog Box (p. 2033).

**Figure 7.6: Copy Case Material Dialog Box**
a. In the Copy Case Material Dialog Box (p. 2033), select the materials that you want to copy.

To select all the materials, click the shaded icon to the right of the Case Materials title. Clicking on the unshaded icon will deselect the selections in the list.

b. Click Copy and close the dialog box.

---

**Note**

Do not copy materials one by one. This will result in previously copied materials getting overwritten by the new ones. Instead, select all the materials to be copied and click Copy.

---

### 7.1.4.5. Modifying Properties of an Existing Material

You can modify the properties of an existing material and use the modified material in the problem setup and save the modified material to the materials database.

1. In the Materials Task Page (p. 2020), click the User-Defined Database... button and open the database that you want to use.

   a. In the User-Defined Database Materials Dialog Box (p. 2032) of the selected database, select the type of material (fluid, solid, etc.) in the Material Type drop-down list.

   b. In the User-Defined Fluid Materials list, User-Defined Solid Materials list, or other similarly named list (the name of the list will be the same as the material type you selected in the previous step), select the material to be modified.

   c. Click Edit... to open the Material Properties Dialog Box (p. 2033).

      i. In the Materials Properties list, select the property to be modified and click Edit... to open the Edit Property Methods Dialog Box (p. 2034).

      ii. Select the method to be modified in the Material Properties list of the Edit Property Methods Dialog Box (p. 2034) and click Edit... under Edit Properties, in order to modify the properties.

      iii. Make the changes in the corresponding method dialog box and click OK.

   d. To use the modified material in the problem setup, click Copy in the User-Defined Database Materials Dialog Box (p. 2032).

   e. To save the modified material to the database, click Save and close the dialog box.

### 7.1.4.6. Creating a New Materials Database and Materials

Using the User-Defined Database Materials Dialog Box (p. 2032), you can create a new materials database, copy materials to this database, and also create new materials from scratch. The procedure for creating a new database and add new materials to the database is as follows:

1. In the Materials Task Page (p. 2020), click User-Defined Database....
2. In the **Open Database Dialog Box** (p. 2031), enter the name of the database that you are creating and click **OK**.

3. A dialog box will appear asking you confirm the creation of a new file. Click **Yes** to confirm.

   *This will open a blank **User-Defined Database Materials Dialog Box** (p. 2032) (Figure 7.7: **User-Defined Database Materials Dialog Box: Blank** (p. 409)).*

**Figure 7.7: User-Defined Database Materials Dialog Box: Blank**

4. Click **New...** in the **User-Defined Database Materials Dialog Box** (p. 2032). This will open a blank **Material Properties** dialog box.
a. In the Material Properties Dialog Box (p. 2033), under Types, select the material type. You can select from fluid, solid, inert-particle, droplet-particle, combusting-particle, and mixture materials.

b. Enter the name and formula (if required) of the material that you are creating in the Name and Formula fields.

c. Depending on the type of material selected in the Types list, properties applicable to that material type will appear in the Available Properties list. Select the properties that are applicable for the material that you are defining by clicking on them.

d. Click the \(\gg\) button to move these properties to the Material Properties list on the right and click Apply. You can use the \(\ll\) button to move the property from the Material Properties list to the Available Properties list.

5. To edit the parameters that define a property, select the property in the Material Properties list and click Edit... This opens the Edit Property Methods Dialog Box (p. 2034).
The methods that can be used to define the selected property are listed in the Available Properties list. You can select one or more methods and specify them for the material that you are defining, by selecting and moving them to the Material Properties list.

To modify each of these methods, you can select the method in the Edit Properties drop-down list and click Edit... This will open the corresponding property dialog box, where you can modify the parameters used by the property method. Refer to Defining Properties Using Temperature-Dependent Functions (p. 412) to Real Gas Models (p. 468) for details of these properties, methods used to define the properties and the parameters for each method.

c. Click OK in the Edit Property Methods Dialog Box (p. 2034).

6. Click Apply in the Material Properties Dialog Box (p. 2033).

7. Click Save in the User-Defined Database Materials Dialog Box (p. 2032) to save the changes to the new materials database.

Similarly, you can also append new materials and click save to append these materials to the existing database.

7.1.4.7. Deleting Materials from a Database

To delete a material from a database, click the User-Defined Database button in the Open Database Dialog Box (p. 2031). Select the database and click OK in the Open Database Dialog Box (p. 2031). Select the Material Type and the materials that you want to delete in the User-Defined Materials list and click Delete. Click Save to save the database.
7.2. Defining Properties Using Temperature-Dependent Functions

Material properties can be defined as functions of temperature. For most properties, you can define a polynomial, piecewise-linear, or piecewise-polynomial function of temperature.

- polynomial:
  \[ \phi(T) = A_1 + A_2 T + A_3 T^2 + \ldots \]  
  \hfill (7.1)

- piecewise-linear:
  \[ \phi(T) = \phi_n + \frac{\phi_{n+1} - \phi_n}{T_{n+1} - T_n} (T - T_n) \]  
  \hfill (7.2)

  where \( 1 \leq n \leq N \) and \( N \) is the number of segments

- piecewise-polynomial:
  \[ \begin{align*}
  & \text{for } T_{\text{min}}, 1 \leq T < T_{\text{max}}, 1: \phi(T) = A_1 + A_2 T + A_3 T^2 + \ldots \\
  & \text{for } T_{\text{min}}, 2 \leq T < T_{\text{max}}, 2: \phi(T) = B_1 + B_2 T + B_3 T^2 + \ldots 
  \end{align*} \]  
  \hfill (7.3)

In the equations above, \( \phi \) is the property.

---

**Important**

If you define a polynomial or piecewise-polynomial function of temperature, the temperature in the function is always in units of Kelvin or Rankine. If you use Celsius or Kelvin as the temperature unit, then polynomial coefficient values must be entered in terms of Kelvin. If you use Fahrenheit or Rankine as the temperature unit, enter the values in terms of Rankine.

Some properties have additional functions available and for some only a subset of these three functions can be used. See the section on the property in question to determine which temperature-dependent functions you can use.

For additional information, see the following sections:

- 7.2.1. Inputs for Polynomial Functions
- 7.2.2. Inputs for Piecewise-Linear Functions
- 7.2.3. Inputs for Piecewise-Polynomial Functions
- 7.2.4. Checking and Modifying Existing Profiles

### 7.2.1. Inputs for Polynomial Functions

To define a polynomial function of temperature for a material property, do the following:

1. In the Create/Edit Materials Dialog Box (p. 2022), choose **polynomial** in the drop-down list to the right of the property name (for example, **Viscosity**). The Polynomial Profile Dialog Box (p. 2036) (Figure 7.10: The Polynomial Profile Dialog Box (p. 413)) will open automatically.
Since this is a modal dialog box, the solver will not allow you to do anything else until you perform the following steps.

a. Specify the number of **Coefficients** up to 8 coefficients are available. The number of coefficients defines the order of the polynomial. The default of 1 defines a polynomial of order 1. An input of 2 defines a polynomial of order 1 and the property will vary linearly with temperature and so on.

b. Define the coefficients. Coefficients $1, 2, 3, \ldots$ correspond to $A_1, A_2, A_3, \ldots$ in Equation 7.1 (p. 412). The dialog box in **Figure 7.10: The Polynomial Profile Dialog Box** (p. 413) shows the inputs for the following function:

$$
\rho (T) = 1000 - 0.02T
$$

(7.4)

**Important**

To ensure the robustness of simulations when using polynomials to specify material property, set the solution limits so that the values returned by the polynomial expression are physically valid. For example, when the density of a material is specified as a function of temperature using a polynomial expression, set the proper limits on the temperature range so that the density is always non-negative. For more information on setting solution limits see Setting Solution Limits (p. 1440).

Also, note the restriction on the units for temperature, as described in the previous section.

### 7.2.2. Inputs for Piecewise-Linear Functions

To define a piecewise-linear function of temperature for a material property, do the following:

1. In the Create/Edit Materials Dialog Box (p. 2022), choose **piecewise-linear** in the drop-down list to the right of the property name (for example, **Viscosity**). The Piecewise-Linear Profile Dialog Box (p. 2036) (Figure 7.11: The Piecewise-Linear Profile Dialog Box (p. 414)) will open automatically.
Figure 7.11: The Piecewise-Linear Profile Dialog Box

Since this is a modal dialog box, the solver will not allow you to do anything else until you perform the following steps.

a. Set the number of Points defining the piecewise distribution.

b. Under Data Points, enter the data pairs for each point. First enter the independent and dependent variable values for Point 1, then increase the Point number and enter the appropriate values for each additional pair of variables. The pairs of points must be supplied in the order of increasing value of temperature. The solver will not sort them for you. A maximum of 50 piecewise points can be defined for each property. The dialog box in Figure 7.11: The Piecewise-Linear Profile Dialog Box (p. 414) shows the final inputs for the profile depicted in Figure 7.12: Piecewise-Linear Definition of Viscosity as a Function of Temperature (p. 414).

---

Important

If the temperature exceeds the maximum Temperature \( T_{\text{max}} \) you have specified for the profile, ANSYS Fluent will use the Value corresponding to \( T_{\text{max}} \). If the temperature falls below the minimum Temperature \( T_{\text{min}} \) specified for your profile, ANSYS Fluent will use the Value corresponding to \( T_{\text{min}} \).

---

Figure 7.12: Piecewise-Linear Definition of Viscosity as a Function of Temperature
7.2.3. Inputs for Piecewise-Polynomial Functions

To define a piecewise-polynomial function of temperature for a material property, follow these steps:

1. In the Create/Edit Materials Dialog Box (p. 2022), choose piecewise-polynomial in the drop-down list to the right of the property name (for example, \(C_p\)). The Piecewise-Polynomial Profile Dialog Box (p. 2037) (Figure 7.13: The Piecewise-Polynomial Profile Dialog Box (p. 415)) will open automatically. Since this is a modal dialog box, first perform the following steps.

2. Specify the number of Ranges. For the example of Equation 7.5 (p. 415), two ranges of temperatures are defined:

\[
c_p(T) = \begin{cases} 
429.929 + 1.784T - 1.966 \times 10^{-3}T^2 + 1.297 \times 10^{-6}T^3 - 4.000 \times 10^{-10}T^4 & \text{for } 300 \leq T < 1000 \\
841.377 + 0.593T - 2.415 \times 10^{-4}T^2 + 4.523 \times 10^{-8}T^3 - 3.153 \times 10^{-12}T^4 & \text{for } 1000 \leq T < 5000 
\end{cases}
\] (7.5)

You may define up to three ranges. The ranges must be supplied in the order of increasing value of temperature. The solver will not sort them for you.

3. For the first range (Range = 1), specify the Minimum and Maximum temperatures, and the number of Coefficients. (Up to eight coefficients are available.) The number of coefficients defines the order of the polynomial. The default of 1 defines a polynomial of order 0. The property will be constant and equal to the single coefficient \(A_1\). An input of 2 defines a polynomial of order 1. The property will vary linearly with temperature and so on.

4. Define the coefficients. Coefficients 1, 2, 3,... correspond to \(A_1, A_2, A_3,...\) in Equation 7.3 (p. 412). The dialog box in Figure 7.13: The Piecewise-Polynomial Profile Dialog Box (p. 415) shows the inputs for the first range of Equation 7.5 (p. 415).
5. Increase the value of **Range** and enter the **Minimum** and **Maximum** temperatures, number of **Coefficients**, and the **Coefficients** \( (B_1, B_2, B_3, \ldots) \) for the next range. Repeat if there is a third range.

### 7.2.4. Checking and Modifying Existing Profiles

If you want to check or change the coefficients, data pairs, or ranges for a previously-defined profile, click the **Edit...** button to the right of the property name. The appropriate dialog box will open, and you can check or modify the inputs as desired.

**Important**

In the **Fluent Database Materials Dialog Box** (p. 2030), you cannot edit the profiles, but you can examine them by clicking on the **View...** button (instead of the **Edit...** button.)

### 7.3. Density

ANSYS Fluent provides several options for definition of the fluid density:

- constant density
- temperature and/or composition-dependent density
- pressure-dependent density

Each of these input options and the governing physical models are explained in the following sections. In all cases, you will define the **Density** in the **Create/Edit Materials Dialog Box** (p. 2022).

**Materials**

For additional information, see the following sections:

- **7.3.1. Defining Density for Various Flow Regimes**
- **7.3.2. Input of Constant Density**
- **7.3.3. Inputs for the Boussinesq Approximation**
- **7.3.4. Compressible Liquid Density Method**
- **7.3.5. Density as a Profile Function of Temperature**
- **7.3.6. Incompressible Ideal Gas Law**
- **7.3.7. Ideal Gas Law for Compressible Flows**
- **7.3.8. Composition-Dependent Density for Multicomponent Mixtures**

### 7.3.1. Defining Density for Various Flow Regimes

The selection of density in ANSYS Fluent is very important. Set the density relationship based on your flow regime.

- For compressible flows, the ideal gas law is the appropriate density relationship.
- For incompressible flows, you may choose one of the following methods:
  - Constant density, if you do not want density to be a function of temperature.
– The incompressible ideal gas law, when pressure variations are small enough that the flow is fully incompressible but you want to use the ideal gas law to express the relationship between density and temperature (for example, for a natural convection problem).

– Density as a polynomial, piecewise-linear, or piecewise-polynomial function of temperature, when the density is a function of temperature only, as in a natural convection problem.

– The Boussinesq model, for natural convection problems involving small changes in temperature.

– The compressible liquid density method allows you to model compressible liquids under high pressures.

### 7.3.1.1. Mixing Density Relationships in Multiple-Zone Models

If your model has multiple fluid zones that use different materials, you should be aware of the following:

- For calculations with the pressure-based solver that do not use one of the general multiphase models (Solution Strategies for Multiphase Modeling (p. 1366)), the compressible ideal gas law cannot be mixed with any other density methods. This means that if the compressible ideal gas law is used for one material, it must be used for all materials.

  This restriction does not apply to the density-based solvers.

- There is only one specified operating pressure and one specified operating temperature. This means that if you are using the ideal gas law for more than one material, they will share the same operating pressure. If you are using the Boussinesq model for more than one material, they will share the same operating temperature.

### 7.3.2. Input of Constant Density

If you want to define the density of the fluid as a constant, select constant in the Density drop-down list under Properties in the Create/Edit Materials Dialog Box (p. 2022). Enter the value of density for the material.

For the default fluid (air), the density is 1.225 kg/m³.

### 7.3.3. Inputs for the Boussinesq Approximation

To enable the Boussinesq approximation for density, choose boussinesq from the Density drop-down list in the Create/Edit Materials Dialog Box (p. 2022) and specify a constant value for Density. You will also need to set the Thermal Expansion Coefficient, as well as relevant operating conditions, as described in The Boussinesq Model (p. 766).

### 7.3.4. Compressible Liquid Density Method

The compressible liquid treatment enables you to model liquid compressibility under high pressure applications. Fluent models compressible liquids using the Tait equation of state, which establishes a nonlinear relationship between density and pressure under isothermal conditions.

The compressible liquid treatment also helps in reducing unphysical pressure spikes that appear in moving and dynamic mesh applications, especially during solid-fluid interactions.

The Tait equation can be represented in terms of pressure and density using the following relationship:

\[ p = a + b \rho^n \]  

(7.6)
where, \(a\) and \(b\) are coefficients that can be determined by assuming that the bulk modulus is a linear function of pressure. The values of coefficients \(a\) and \(b\) are based on the reference state values of pressure, density, and bulk modulus.

The simplified form of the Tait equation can be written as:

\[
\left(\frac{\rho}{\rho_0}\right)^n = \frac{K}{K_0}
\]  
(7.7)

where,

\[K = K_0 + n\Delta p\]  
(7.8)

and

\[\Delta p = p - p_0\]  
(7.9)

where,

\[
\begin{align*}
\rho_0 &= \text{Reference liquid pressure (Absolute)} \\
\rho_0 &= \text{Reference liquid density (Density at reference pressure, } p_0) \\
K_0 &= \text{Reference bulk modulus (Bulk modulus at reference pressure, } p_0) \\
n &= \text{Density exponent} \\
p &= \text{Liquid pressure (Absolute)} \\
\rho &= \text{Liquid density at pressure, } p \\
K &= \text{Bulk modulus at pressure, } p
\end{align*}
\]

The speed of sound, \(c\), is calculated as:

\[
c = \sqrt{\frac{K}{\rho}}
\]  
(7.10)

---

**Note**

You can postprocess the speed of sound for compressible liquid materials. For multiphase models, sound-speed postprocessing is available at mixture and/or phase level, depending on the model selected. Sound-speed postprocessing is also enabled if you describe the speed of sound for a user-defined density.

---

### 7.3.4.1. Compressible Liquid Inputs

Select the **compressible-liquid** under **Density** in the **Create/Edit Materials** panel as seen in [Figure 7.14: Compressible Liquid Materials Setting](p. 419).
Figure 7.14: Compressible Liquid Materials Setting

In the **Compressible Liquid** dialog box you need to specify values for the following settings:

- Reference Pressure
- Reference Density
- Reference Bulk Modulus
- Density Exponent
Note

ANSYS Fluent automatically fills user input values for certain materials based on open literature. For cases where there is no data available, Fluent fills in a value of zero. Because compressible liquid treatment is common for water-liquid, the chosen value for the default input of the density exponent is set close to the value for water-liquid. You need to verify the values of the default input for your application.

You can set the compressible-liquid density method using the following text command:

```
define → materials → change-create
```

In the text command interface, set the `change` Density? option to yes, and set new method [constant] to compressible-liquid as shown below:

```
/define/materials> change-create

material-name> water-liquid
material name (water-liquid)
water-liquid is a fluid
change Density? [no] yes

new method [constant] compressible-liquid
Reference Pressure (pascal) [101325]
Reference Density (kg/m3) [998.2000000000001]
Reference Bulk Modulus (pascal) [2200000000]
Density Exponent [7.15]
```

7.3.4.2. Compressible Liquid Density Method Availability

The compressible liquid density method is available with fluid materials or with components of a mixture material having the density method set to volume-weighted-mixing-law for both single and multiphase cases.

This method is not available with the density-based solver.
7.3.5. Density as a Profile Function of Temperature

If you are modeling a problem that involves heat transfer, you can define the density as a function of temperature. Three types of functions are available:

- **piecewise-linear:**
  \[
  \rho(T) = \rho_n + \frac{\rho_{n+1} - \rho_n}{T_{n+1} - T_n} (T - T_n)
  \]  
  (7.11)

- **piecewise-polynomial:**
  \[
  \begin{align*}
  \text{for } & \ T_{\text{min}}, 1 \leq T < T_{\text{max}}, 1: \rho(T) = A_1 + A_2 T + A_3 T^2 + \ldots \\
  \text{for } & \ T_{\text{min}}, 2 \leq T < T_{\text{max}}, 2: \rho(T) = B_1 + B_2 T + B_3 T^2 + \ldots
  \end{align*}
  \]  
  (7.12)

- **polynomial:**
  \[
  \rho(T) = A_1 + A_2 T + A_3 T^2 + \ldots
  \]  
  (7.13)

For one of these methods, select **piecewise-linear**, **piecewise-polynomial**, or **polynomial** in the **Density** drop-down list. You can enter the data pairs \((T_n, \rho_n)\), ranges and coefficients, or coefficients that describe these functions using the Create/Edit Materials Dialog Box (p. 2022), as described in Defining Properties Using Temperature-Dependent Functions (p. 412).

7.3.6. Incompressible Ideal Gas Law

In ANSYS Fluent, if you choose to define the density using the ideal gas law for an incompressible flow, the solver will compute the density as

\[
\rho = \frac{p_{\text{op}}}{R} \frac{T}{M_w}
\]  
(7.14)

where,

- \(R\) = the universal gas constant
- \(M_w\) = the molecular weight of the gas
- \(p_{\text{op}}\) = the operating pressure

In this form, the density depends only on the operating pressure and not on the local relative pressure field.

7.3.6.1. Density Inputs for the Incompressible Ideal Gas Law

The inputs for the incompressible ideal gas law are as follows:

1. Enable the ideal gas law for an incompressible fluid by choosing **incompressible-ideal-gas** from the drop-down list to the right of **Density** in the Create/Edit Materials Dialog Box (p. 2022).

Specify the incompressible ideal gas law individually for each material that you want to use it for. See Composition-Dependent Density for Multicomponent Mixtures (p. 423) for information on specifying the incompressible ideal gas law for mixtures.
2. Set the operating pressure by defining the **Operating Pressure** in the **Operating Conditions Dialog Box** (p. 2095).

![Cell Zone Conditions → Operating Conditions...](image)

**Important**

By default, operating pressure is set to 101325 Pa. The input of the operating pressure is of great importance when you are computing density with the ideal gas law. See **Operating Pressure** (p. 466) for recommendations on setting appropriate values for the operating pressure.

3. Set the molecular weight of the homogeneous or single-component fluid (if no chemical species transport equations are to be solved), or the molecular weights of each fluid material (species) in a multicomponent mixture. For each fluid material, enter the value of the **Molecular Weight** in the **Create/Edit Materials Dialog Box** (p. 2022).

### 7.3.7. Ideal Gas Law for Compressible Flows

For compressible flows, the gas law is as following:

\[
\rho = \frac{p_{op} + p}{\frac{R}{M_w} T}
\]  

(7.15)

where,

- \(p\) = the local relative (or gauge) pressure predicted by ANSYS Fluent
- \(p_{op}\) = the operating pressure

#### 7.3.7.1. Density Inputs for the Ideal Gas Law for Compressible Flows

The inputs for the ideal gas law are as follows:

1. Enable the ideal gas law for a compressible fluid by choosing **ideal-gas** from the drop-down list to the right of **Density** in the **Create/Edit Materials Dialog Box** (p. 2022).

   Specify the ideal gas law individually for each material that you want to use it for. See **Composition-Dependent Density for Multicomponent Mixtures** (p. 423) for information on specifying the ideal gas law for mixtures.

2. Set the operating pressure by defining the **Operating Pressure** in the **Operating Conditions Dialog Box** (p. 2095).

![Cell Zone Conditions → Operating Conditions...](image)

**Important**

The input of the operating pressure is of great importance when you are computing density with the ideal gas law. **Equation 7.15** (p. 422) notes that the operating pressure is
added to the relative pressure field computed by the solver, yielding the absolute static pressure. See Operating Pressure (p. 466) for recommendations on setting appropriate values for the operating pressure. By default, operating pressure is set to 101325 Pa.

3. Set the molecular weight of the homogeneous or single-component fluid (if no chemical species transport equations are to be solved), or the molecular weights of each fluid material (species) in a multicomponent mixture. For each fluid material, enter the value of the Molecular Weight in the Create/Edit Materials Dialog Box (p. 2022).

7.3.8. Composition-Dependent Density for Multicomponent Mixtures

If you are solving species transport equations, set properties for the mixture material and for the constituent fluids (species), as described in detail in Defining Properties for the Mixture and Its Constituent Species (p. 892). To define a composition-dependent density for a mixture, do the following:

1. Select the density method:
   • For non-ideal-gas mixtures, select the volume-weighted-mixing-law method for the mixture material in the drop-down list to the right of Density in the Create/Edit Materials Dialog Box (p. 2022).
   • If you are modeling compressible flow, select ideal-gas for the mixture material in the drop-down list to the right of Density in the Create/Edit Materials Dialog Box (p. 2022).
   • If you are modeling incompressible flow using the ideal gas law, select incompressible-ideal-gas for the mixture material in the Density drop-down list in the Create/Edit Materials Dialog Box (p. 2022).
   • If you have a user-defined function that you want to use to model the density, you can choose either the user-defined method or the user-defined-mixing-law method for the mixture material in the drop-down list.

   The only difference between the user-defined-mixing-law and the user-defined option for specifying density, viscosity and thermal conductivity of mixture materials, is that with the user-defined-mixing-law option, the individual properties of the species materials can also be specified. (Note that only the constant, the polynomial methods and the user-defined methods are available.)

2. Click Change/Create.

3. If you have selected volume-weighted-mixing-law, define the density for each of the fluid materials that comprise the mixture. You may define constant or compressible-liquid or (if applicable) temperature-dependent densities for the individual species.

4. If you selected user-defined-mixing-law, define the density for each of the fluid materials that comprise the mixture. You may define constant, or (if applicable) temperature-dependent densities, or user-defined densities for the individual species. More information on defining properties with user-defined functions can be found in the UDF Manual.

If you are modeling a non-ideal-gas mixture, ANSYS Fluent will compute the mixture density as

\[
\rho = \frac{1}{\sum_i \frac{Y_i}{\rho_i}}
\]  

(7.16)

where \( Y_i \) is the mass fraction and \( \rho_i \) is the density of species \( i \).
For compressible flows, the gas law has the following form:

$$\rho = \frac{p_{op} + p}{RT \sum_i \frac{Y_i}{M_{w,i}}}$$  \hspace{1cm} (7.17)

where,

- $p$ = the local relative (or gauge) pressure predicted by ANSYS Fluent
- $R$ = the universal gas constant
- $Y_i$ = the mass fraction of species $i$
- $M_{w,i}$ = the molecular weight of species $i$
- $p_{op}$ = the operating pressure

In ANSYS Fluent, if you choose to define the density using the ideal gas law for an incompressible flow, the solver will compute the density as

$$\rho = \frac{p_{op}}{RT \sum_i \frac{Y_i}{M_{w,i}}}$$  \hspace{1cm} (7.18)

where,

- $R$ = the universal gas constant
- $Y_i$ = the mass fraction of species $i$
- $M_{w,i}$ = the molecular weight of species $i$
- $p_{op}$ = the operating pressure

### 7.4. Viscosity

ANSYS Fluent provides several options for definition of the fluid viscosity:

- constant viscosity
- temperature dependent and/or composition-dependent viscosity
- kinetic theory
- non-Newtonian viscosity
- user-defined function

Each of these input options and the governing physical models are detailed in this section. (User-defined functions are described in the UDF Manual). In all cases, define the **Viscosity** in the Create/Edit Materials Dialog Box (p. 2022).
Viscosities are input as dynamic viscosity ($\mu$) in units of kg/m-s in SI units or lb/ft-s in British units. ANSYS Fluent does not ask for input of the kinematic viscosity ($\nu$).

For additional information, see the following sections:
- 7.4.1. Input of Constant Viscosity
- 7.4.2. Viscosity as a Function of Temperature
- 7.4.3. Defining the Viscosity Using Kinetic Theory
- 7.4.4. Composition-Dependent Viscosity for Multicomponent Mixtures
- 7.4.5. Viscosity for Non-Newtonian Fluids

### 7.4.1. Input of Constant Viscosity

If you want to define the viscosity of your fluid as a constant, select constant in the Viscosity drop-down list in the Create/Edit Materials Dialog Box (p. 2022), and enter the value of viscosity for the fluid.

For the default fluid (air), the viscosity is $1.7894 \times 10^{-5}$ kg/m-s.

### 7.4.2. Viscosity as a Function of Temperature

If you are modeling a problem that involves heat transfer, you can define the viscosity as a function of temperature. Five types of functions are available.

- piecewise-linear:
  $$\mu (T) = \mu_n + \frac{\mu_{n+1} - \mu_n}{T_{n+1} - T_n} (T - T_n)$$  
  \hfill (7.19)

- piecewise-polynomial:
  For $T_{\text{min}} < T < T_{\text{max}}$, 1:
  $$\mu (T) = A_1 + A_2 T + A_3 T^2 + \ldots$$  
  \hfill (7.20)

  For $T_{\text{min}} < T < T_{\text{max}}$, 2:
  $$\mu (T) = B_1 + B_2 T + B_3 T^2 + \ldots$$  
  \hfill (7.21)

- polynomial:
  $$\mu (T) = A_1 + A_2 T + A_3 T^2 + \ldots$$  
  \hfill (7.21)

- Sutherland’s law

- power law

### Important

The power law described here is different from the non-Newtonian power law described in Viscosity for Non-Newtonian Fluids (p. 429).

For one of the first three, select piecewise-linear, piecewise-polynomial, polynomial in the Viscosity drop-down list and then enter the data pairs ($T_n$, $\mu_n$), ranges and coefficients, or coefficients that describe these functions Defining Properties Using Temperature-Dependent Functions (p. 412). For Sutherland’s law or the power law, choose sutherland or power-law respectively in the drop-down list and enter the parameters.
7.4.2.1. Sutherland Viscosity Law

Sutherland's viscosity law resulted from a kinetic theory by Sutherland (1893) using an idealized intermolecular-force potential. The formula is specified using two or three coefficients.

Sutherland’s law with two coefficients has the form

\[ \mu = \frac{C_1 T^{3/2}}{T + C_2} \]  

(7.22)

where,

\[ \mu = \text{the viscosity in kg/m-s} \]
\[ T = \text{the static temperature in K} \]
\[ C_1 \text{ and } C_2 = \text{the coefficients} \]

For air at moderate temperatures and pressures, \( C_1 = 1.458 \times 10^{-6} \text{ kg/m-s-K}^{1/2} \), and \( C_2 = 110.4 \text{ K} \).

Sutherland’s law with three coefficients has the form

\[ \mu = \mu_0 \left( \frac{T}{T_0} \right)^{3/2} \frac{T_0 + S}{T + S} \]  

(7.23)

where,

\[ \mu = \text{the viscosity in kg/m-s} \]
\[ T = \text{the static temperature in K} \]
\[ \mu_0 = \text{reference value in kg/m-s} \]
\[ T_0 = \text{reference temperature in K} \]
\[ S = \text{an effective temperature in K (Sutherland constant)} \]

For air at moderate temperatures and pressures, \( \mu_0 = 1.716 \times 10^{-5} \text{ kg/m-s}, T_0 = 273.11 \text{ K}, \) and \( S = 110.56 \text{ K} \).

7.4.2.1.1. Inputs for Sutherland’s Law

To use Sutherland’s law, choose sutherland in the drop-down list to the right of Viscosity. The Sutherland Law Dialog Box (p. 2040) will open, and you can enter the coefficients as follows:

1. Select the Two Coefficient Method or the Three Coefficient Method.

   **Important**

   Use SI units if you choose the two-coefficient method.

2. For the Two Coefficient Method, set \( C_1 \) and \( C_2 \). For the Three Coefficient Method, set the Reference Viscosity \( \mu_0 \), the Reference Temperature \( T_0 \), and the Effective Temperature \( S \).
7.4.2.2. Power-Law Viscosity Law

Another common approximation for the viscosity of dilute gases is the power-law form. For dilute gases at moderate temperatures, this form is considered to be slightly less accurate than Sutherland’s law.

A power-law viscosity law with two coefficients has the form

\[ \mu = B T^n \tag{7.24} \]

where,

\[ \mu = \text{the viscosity in kg/m-s} \]
\[ T = \text{the static temperature in K} \]
\[ B = \text{a dimensional coefficient} \]

For air at moderate temperatures and pressures, \( B = 4.093 \times 10^{-7} \), and \( n = 2/3 \).

A power-law viscosity law with three coefficients has the form

\[ \mu = \mu_0 \left( \frac{T}{T_0} \right)^n \tag{7.25} \]

where,

\[ \mu = \text{the viscosity in kg/m-s} \]
\[ T = \text{the static temperature in K} \]
\[ T_0 = \text{a reference value in K} \]
\[ \mu_0 = \text{a reference value in kg/m-s} \]

For air at moderate temperatures and pressures, \( \mu_0 = 1.716 \times 10^{-5} \text{ kg/m-s}, T_0 = 273 \text{ K}, \) and \( n = 2/3 \).

---

**Important**

The non-Newtonian power law for viscosity is described in Viscosity for Non-Newtonian Fluids (p. 429).

---

7.4.2.2.1. Inputs for the Power Law

To use the power law, choose power-law in the drop-down list to the right of Viscosity. The Power Law Dialog Box (p. 2040) will open, and you can enter the coefficients as follows:

1. Select the Two Coefficient Method or the Three Coefficient Method.

---

**Important**

Note that you must use SI units if you choose the two-coefficient method.
2. For the Two Coefficient Method, set $B$ and the Temperature Exponent $n$. For the Three Coefficient Method, set the Reference Viscosity $\mu_0$, the Reference Temperature $T_0$, and the Temperature Exponent $n$.

### 7.4.3. Defining the Viscosity Using Kinetic Theory

If you are using the ideal gas law (as described in Density (p. 416)), you have the option to define the fluid viscosity using kinetic theory as

$$\mu = 2.67 \times 10^{-6} \frac{M_w T}{\sigma^2 \Omega_\mu}$$  \hfill (7.26)

where,

- $\mu$ is in units of kg/m-s,
- $T$ is in units of Kelvin
- $\sigma$ is in units of Angstroms
- $\Omega_\mu = \Omega_{\mu}(T^*)$
- $M_w$ is the molecular weight

where

$$T^* = \frac{T}{(\varepsilon/k_B)}$$  \hfill (7.27)

The Lennard-Jones parameters, $\sigma$ and $\varepsilon/k_B$, are inputs to the kinetic theory calculation that you supply by selecting kinetic-theory from the drop-down list to the right of Viscosity in the Create/Edit Materials Dialog Box (p. 2022). The solver will use these kinetic theory inputs in Equation 7.26 (p. 428) to compute the fluid viscosity. See Kinetic Theory Parameters (p. 465) for details about these inputs.

### 7.4.4. Composition-Dependent Viscosity for Multicomponent Mixtures

If you are modeling a flow that includes more than one chemical species (multicomponent flow), you have the option to define a composition-dependent viscosity. (Note that you can also define the viscosity of the mixture as a constant value or a function of temperature.)

To define a composition-dependent viscosity for a mixture, follow these steps:

1. For the mixture material, choose mass-weighted-mixing-law or, if you are using the ideal gas law for density, ideal-gas-mixing-law in the drop-down list to the right of Viscosity. If you have a user-defined function that you want to use to model the viscosity, you can choose either the user-defined method or the user-defined-mixing-law method for the mixture material in the drop-down list.

2. Click Change/Create.

3. Define the viscosity for each of the fluid materials that comprise the mixture. You may define constant or (if applicable) temperature-dependent viscosities for the individual species. You may also use kinetic theory for the individual viscosities, or specify a non-Newtonian viscosity, if applicable.

4. If you selected user-defined-mixing-law, define the viscosity for each of the fluid materials that comprise the mixture. You may define constant, or (if applicable) temperature-dependent viscosities, or user-defined
viscosities for the individual species. More information on defining properties with user-defined functions can be found in the UDF Manual.

The only difference between the user-defined-mixing-law and the user-defined option for specifying density, viscosity and thermal conductivity of mixture materials, is that with the user-defined-mixing-law option, the individual properties of the species materials can also be specified. (Note that only the constant, the polynomial methods and the user-defined methods are available.)

If you are using the ideal gas law, the solver will compute the mixture viscosity based on kinetic theory as

$$\mu = \frac{\sum_i X_i \mu_i}{\sum_j X_j \phi_{ij}}$$

(7.28)

where

$$\phi_{ij} = \left[ 1 + \left( \frac{\mu_i}{\mu_j} \right)^{1/2} \left( \frac{M_{w,j}}{M_{w,i}} \right)^{1/4} \right]^2$$

(7.29)

and $X_i$ is the mole fraction of species $i$.

For non-ideal gas mixtures, the mixture viscosity is computed based on a simple mass fraction average of the pure species viscosities:

$$\mu = \sum_i Y_i \mu_i$$

(7.30)

### 7.4.5. Viscosity for Non-Newtonian Fluids

For incompressible Newtonian fluids, the shear stress is proportional to the rate-of-deformation tensor $\overline{D}$:

$$\tau = \mu \overline{D}$$

(7.31)

where $\overline{D}$ is defined by

$$\overline{D} = \left( \frac{\partial u_j}{\partial x_i} + \frac{\partial u_i}{\partial x_j} \right)$$

(7.32)

and $\mu$ is the viscosity, which is independent of $\overline{D}$.

For some non-Newtonian fluids, the shear stress can similarly be written in terms of a non-Newtonian viscosity $\eta$:

$$\tau = \eta \left( \overline{D} \right) \overline{D}$$

(7.33)
In general, $\eta$ is a function of all three invariants of the rate-of-deformation tensor $\overline{D}$. However, in the non-Newtonian models available in ANSYS Fluent, $\eta$ is considered to be a function of the shear rate $\dot{\gamma}$ only. $\dot{\gamma}$ is related to the second invariant of $\overline{D}$ and is defined as

$$
\dot{\gamma} = \sqrt{\frac{1}{2} \overline{\epsilon} : \overline{\epsilon}}
$$

(7.34)

### 7.4.5.1. Temperature Dependent Viscosity

If the flow is non-isothermal, then the temperature dependence on the viscosity can be included along with the shear rate dependence. In this case, the total viscosity consists of two parts and is calculated as

$$
\mu = \eta(\dot{\gamma}) H(T)
$$

(7.35)

where $H(T)$ is the temperature dependence, known as the Arrhenius law.

$$
H(T) = \exp \left[ \alpha \left( \frac{1}{T - T_0} - \frac{1}{T_\alpha - T_0} \right) \right]
$$

(7.36)

where $\alpha$ is the ratio of the activation energy to the thermodynamic constant and $T_\alpha$ is a reference temperature for which $H(T) = 1$. $T_0$, which is the temperature shift, is set to 0 by default, and corresponds to the lowest temperature that is thermodynamically acceptable. Therefore $T_\alpha$ and $T_0$ are absolute temperatures. Temperature dependence is only included when the energy equation is enabled. Set the parameter $\alpha$ to 0 when you want temperature dependence to be ignored, even when the energy equation is solved.

ANSYS Fluent provides four options for modeling non-Newtonian flows:

- power law
- Carreau model for pseudo-plastics
- Cross model
- Herschel-Bulkley model for Bingham plastics

**Important**

- Note that the models listed above are not available when modeling turbulent flow.
- Note that the non-Newtonian power law described below is different from the power law described in *Power-Law Viscosity Law* (p. 427).
- Non-Newtonian model based on single fluid formulation is available for the mixture model and it is recommended that this should be attached to the primary phase.

Appropriate values for the input parameters for these models can be found in the literature (for example, [105] (p. 2562)).
7.4.5.2. Power Law for Non-Newtonian Viscosity

If you choose non-newtonian-power-law in the drop-down list to the right of Viscosity, non-Newtonian flow will be modeled according to the following power law for the non-Newtonian viscosity:

\[ \eta = k \dot{\gamma}^{n-1} H(T) \]  \hspace{1cm} (7.37)

where \( k \) and \( n \) are input parameters. \( k \) is a measure of the average viscosity of the fluid (the consistency index); \( n \) is a measure of the deviation of the fluid from Newtonian (the power-law index). The value of \( n \) determines the class of the fluid:

- \( n = 1 \rightarrow \) Newtonian fluid
- \( n > 1 \rightarrow \) shear-thickening (dilatant fluids)
- \( n < 1 \rightarrow \) shear-thinning (pseudo-plastics)

7.4.5.2.1. Inputs for the Non-Newtonian Power Law

To use the non-Newtonian power law, choose non-newtonian-power-law in the drop-down list to the right of Viscosity. The Non-Newtonian Power Law Dialog Box (p. 2041) will open, and you can choose between Shear Rate Dependent and Shear Rate and Temperature Dependent. Enter the Consistency Index \( k \), Power-Law Index \( n \), Minimum and Maximum Viscosity Limit, Reference Temperature \( T_{\alpha \text{ref}} \) and Activation Energy/R, \( \alpha \), which is the ratio of the activation energy to the thermodynamic constant.

7.4.5.3. The Carreau Model for Pseudo-Plastics

The power law model described in Equation 7.37 (p. 431) results in a fluid viscosity that varies with shear rate. For \( \dot{\gamma} \to 0, \eta \to \eta_0 \) and for \( \dot{\gamma} \to \infty, \eta \to \eta_\infty \), where \( \eta_0 \) and \( \eta_\infty \) are, respectively, the upper and lower limiting values of the fluid viscosity.

The Carreau model attempts to describe a wide range of fluids by the establishment of a curve-fit to piece together functions for both Newtonian and shear-thinning \((n < 1)\) non-Newtonian laws. In the Carreau model, the viscosity is

\[ \eta = H(T) \left( \eta_\infty + \left( \eta_0 - \eta_\infty \right) \left[ 1 + \dot{\gamma}^2 \lambda^2 \right]^{(n-1)/2} \right) \]  \hspace{1cm} (7.38)

and the parameters \( n, \lambda, T_\alpha, \eta_0, \) and \( \eta_\infty \) are dependent upon the fluid. \( \lambda \) is the time constant, \( n \) is the power-law index (as described above for the non-Newtonian power law), \( \eta_0 \) and \( \eta_\infty \) are, respectively, the zero- and infinite-shear viscosities, \( T_\alpha \) is the reference temperature, and \( \alpha \) is the ratio of the activation energy to thermodynamic constant. Figure 7.16: Variation of Viscosity with Shear Rate According to the Carreau Model (p. 432) shows how viscosity is limited by \( \eta_0 \) and \( \eta_\infty \) at low and high shear rates.
7.4.5.3.1. Inputs for the Carreau Model

To use the Carreau model, choose `carreau` in the drop-down list to the right of `Viscosity`. The Carreau Model Dialog Box (p. 2042) will open, and you can choose between Shear Rate Dependent and Shear Rate and Temperature Dependent. Enter the Time Constant $\lambda$, Power-Law Index $n$, Reference Temperature $T_c$, Zero Shear Viscosity $\eta_0'$, Infinite Shear Viscosity $\eta_\infty'$, and Activation Energy/R $\alpha$.

7.4.5.4. Cross Model

The Cross model for viscosity is:

$$\eta = H(T) \frac{\eta_0}{1 + (\lambda \dot{\gamma})^{1-n}} \tag{7.39}$$

where,

$$\eta_0 = \text{zero-shear-rate viscosity}$$
\[ \dot{\lambda} = \text{natural time (that is, inverse of the shear rate at which the fluid changes from Newtonian to power-law behavior)} \]
\[ n = \text{power-law index} \]

The Cross model is commonly used to describe the low-shear-rate behavior of the viscosity.

### 7.4.5.4.1. Inputs for the Cross Model

To use the Cross model, choose `cross` in the drop-down list to the right of `Viscosity`. The Cross Model Dialog Box (p. 2043) will open, and you can choose between `Shear Rate Dependent` and `Shear Rate and Temperature Dependent`. Enter the **Zero Shear Viscosity** \( \eta_0 \), **Time Constant** \( \lambda \), **Power-Law Index** \( n \), **Reference Temperature** \( T_{ref} \) and **Activation Energy/R**, \( \alpha \), which is the ratio of the activation energy to the thermodynamic constant.

### 7.4.5.5. Herschel-Bulkley Model for Bingham Plastics

The power law model described above is valid for fluids for which the shear stress is zero when the strain rate is zero. Bingham plastics are characterized by a non-zero shear stress when the strain rate is zero.

\[ \bar{\tau} = \bar{\tau}_0 + \eta \bar{D} \]  \hspace{1cm} (7.40)

where \( \tau_0 \) is the yield stress:

- For \( \tau < \tau_0 \) the material remains rigid.
- For \( \tau > \tau_0 \) the material flows as a power-law fluid.

The Herschel-Bulkley model combines the effects of Bingham and power-law behavior in a fluid. For low strain rates \( (\dot{\gamma} < \dot{\gamma}_0 / \mu_0) \), the “rigid” material acts like a very viscous fluid with viscosity \( \mu_0 \). As the strain rate increases and the yield stress threshold, \( \tau_0 \), is passed, the fluid behavior is described by a power law.

For \( \dot{\gamma} > \dot{\gamma}_c \)

\[ \eta = \frac{\tau_0}{\dot{\gamma}_c} + k \left( \frac{\dot{\gamma}}{\dot{\gamma}_c} \right)^{n-1} \]  \hspace{1cm} (7.41)

For \( \dot{\gamma} < \dot{\gamma}_c \)

\[ \eta = \frac{2 - \dot{\gamma} / \dot{\gamma}_c}{\dot{\gamma}_c} + k \left( 2 - n \right) + (n - 1) \left( \frac{\dot{\gamma}}{\dot{\gamma}_c} \right)^{n-1} \]  \hspace{1cm} (7.42)

where \( k \) is the consistency factor, and \( n \) is the power-law index.

**Figure 7.18: Variation of Shear Stress with Shear Rate According to the Herschel-Bulkley Model** (p. 434) shows how shear stress \( (\bar{\tau}) \) varies with shear rate \( (\dot{\gamma}) \) for the Herschel-Bulkley model.
If you choose the Herschel-Bulkley model for Bingham plastics, Equation 7.41 (p. 433) will be used to determine the fluid viscosity.

The Herschel-Bulkley model is commonly used to describe materials such as concrete, mud, dough, and toothpaste, for which a constant viscosity after a critical shear stress is a reasonable assumption. In addition to the transition behavior between a flow and no-flow regime, the Herschel-Bulkley model can also exhibit a shear-thinning or shear-thickening behavior depending on the value of $n$.

### 7.4.5.5.1. Inputs for the Herschel-Bulkley Model

To use the Herschel-Bulkley model, choose `herschel-bulkley` in the drop-down list to the right of `Viscosity`. The Herschel-Bulkley Dialog Box (p. 2044) will open, and you can choose between `Shear Rate Dependent` and `Shear Rate and Temperature Dependent`. Enter the `Consistency Index $k$`, `Power-Law Index $n$`, `Yield Stress Threshold $\tau_0$`, `Critical Shear Rate $\dot{y}_c$`, `Reference Temperature $T_{ref}$` and the ratio of the activation energy to thermodynamic constant $\alpha$, `Activation Energy/R`.

### 7.5. Thermal Conductivity

The thermal conductivity must be defined when heat transfer is active. You must define thermal conductivity when you are modeling energy and viscous flow.

ANSYS Fluent provides several options for definition of the thermal conductivity:

- constant thermal conductivity
- temperature- and/or composition-dependent thermal conductivity
- kinetic theory
- anisotropic (anisotropic, biaxial, orthotropic, cylindrical orthotropic, user-defined anisotropic) (for solid materials only)
- user-defined

Each of these input options and the governing physical models are detailed in this section. User-defined functions (UDFs) are described in the UDF Manual.

In all cases, you will define the **Thermal Conductivity** in the Create/Edit Materials Dialog Box (p. 2022) (Figure 7.19: The Create/Edit Materials Dialog Box (p. 435)).
Thermal conductivity is defined in units of W/m-K in SI units or BTU/hr-ft-°R in British units.

For additional information, see the following sections:
7.5.1. Constant Thermal Conductivity
7.5.2. Thermal Conductivity as a Function of Temperature
7.5.3. Thermal Conductivity Using Kinetic Theory
7.5.4. Composition-Dependent Thermal Conductivity for Multicomponent Mixtures
7.5.5. Anisotropic Thermal Conductivity for Solids

7.5.1. Constant Thermal Conductivity

If you want to define the thermal conductivity as a constant, check that constant is selected in the drop-down list to the right of Thermal Conductivity in the Create/Edit Materials Dialog Box (p. 2022) (Figure 7.19: The Create/Edit Materials Dialog Box (p. 435)), and enter the value of thermal conductivity for the material.

For the default fluid (air), the thermal conductivity is 0.0242 W/m-K.

7.5.2. Thermal Conductivity as a Function of Temperature

You can also choose to define the thermal conductivity as a function of temperature. Three types of functions are available:

• piecewise-linear:
7.43. Piecewise-Polynomial Thermal Conductivity

- Piecewise-polynomial:

\[ k(T) = k_n + \frac{k_{n+1} - k_n}{T_{n+1} - T_n} (T - T_n) \]  

for \( T_{min,1} \leq T < T_{max,1} \):

\[ k(T) = A_1 + A_2 T + A_3 T^2 + \ldots \]  

for \( T_{min,2} \leq T < T_{max,2} \):

\[ k(T) = B_1 + B_2 T + B_3 T^2 + \ldots \]  

7.44. Polynomial Thermal Conductivity

- Polynomial:

\[ k(T) = A_1 + A_2 T + A_3 T^2 + \ldots \]  

7.5.3. Thermal Conductivity Using Kinetic Theory

If you are using the ideal gas law (as described in Density (p. 416)), you have the option to define the thermal conductivity using kinetic theory as

\[ k = \frac{15}{4} \frac{R}{M_w} \mu \left[ \frac{4}{15} \frac{c_p M_w}{R} + \frac{1}{3} \right] \]  

where \( R \) is the universal gas constant, \( M_w \) is the molecular weight, \( \mu \) is the material's specified or computed viscosity, and \( c_p \) is the material's specified or computed specific heat capacity.

To enable the use of this equation for calculating thermal conductivity, select kinetic-theory from the drop-down list to the right of Thermal Conductivity in the Create/Edit Materials Dialog Box (p. 2022). The solver will use Equation 7.46 (p. 436) to compute the thermal conductivity.

7.5.4. Composition-Dependent Thermal Conductivity for Multicomponent Mixtures

If you are modeling a flow that includes more than one chemical species (multicomponent flow), you have the option to define a composition-dependent thermal conductivity. (Note that you can also define the thermal conductivity of the mixture as a constant value or a function of temperature, or using kinetic theory.)

To define a composition-dependent thermal conductivity for a mixture, follow these steps:

1. For the mixture material, choose mass-weighted-mixing-law or, if you are using the ideal gas law, ideal-gas-mixing-law in the drop-down list to the right of Thermal Conductivity. If you have a user-defined function that you want to use to model the thermal conductivity, you can choose either the user-defined method or the user-defined-mixing-law method for the mixture material in the drop-down list.

The only difference between the user-defined-mixing-law and the user-defined option for specifying density, viscosity and thermal conductivity of mixture materials, is that with the user-defined-mixing-
law option, the individual properties of the species materials can also be specified. Note that only
the constant, the polynomial methods and the user-defined methods are available.

Important

If you use ideal-gas-mixing-law for the thermal conductivity of a mixture, you must use
ideal-gas-mixing-law or mass-weighted-mixing-law for viscosity, because these two
viscosity specification methods are the only ones that allow specification of the component
viscosities, which are used in the ideal gas law for thermal conductivity (Equation 7.47 (p. 437)).

2. Click Change/Create.

3. Define the thermal conductivity for each of the fluid materials that comprise the mixture. You may define
constant or (if applicable) temperature-dependent thermal conductivities for the individual species. You
may also use kinetic theory for the individual thermal conductivities, if applicable.

4. If you selected user-defined-mixing-law, define the thermal conductivity for each of the fluid materials
that comprise the mixture. You may define constant, or (if applicable) temperature-dependent thermal
conductivities, or user-defined thermal conductivities for the individual species. More information about
defining properties with user-defined functions can be found in the UDF Manual.

If you are using the ideal gas law, the solver will compute the mixture thermal conductivity based on
kinetic theory as

\[ k = \sum_i \frac{X_i k_i}{\sum_j X_j \phi_{ij}} \]  \hspace{1cm} (7.47)

where

\[ \phi_{ij} = \left[ 1 + \left( \frac{\mu_i}{\mu_j} \right)^{1/2} \left( \frac{M_{w,i}}{M_{w,j}} \right)^{1/4} \right]^2 \left( 1 + \frac{M_{w,i}}{M_{w,j}} \right)^{1/2} \]  \hspace{1cm} (7.48)

and \( X_i \) is the mole fraction of species \( i \).

For non-ideal gases, the mixture thermal conductivity is computed based on a simple mass fraction
average of the pure species conductivities:

\[ k = \sum_i Y_i k_i \]  \hspace{1cm} (7.49)

7.5.5. Anisotropic Thermal Conductivity for Solids

The anisotropic conductivity option in ANSYS Fluent solves the conduction equation in solid zones and
shells with the thermal conductivity specified as a matrix. The heat flux vector is written as
The following options are available for defining anisotropic thermal conductivity in ANSYS Fluent. These are discussed below.

- anisotropic
- biaxial (available for shells only)
- orthotropic
- cylindrical orthotropic
- user-defined anisotropic

**Important**

Note that the anisotropic conductivity options are available only with the pressure-based solver; you cannot use them with the density-based solvers.

### 7.5.5.1. Anisotropic Thermal Conductivity

For anisotropic diffusion, the thermal conductivity matrix (Equation 7.50 (p. 438)) is specified as

\[
q_i = -k_{ij} \frac{\partial T}{\partial x_j}
\]

(7.50)

where \( k_{ij} \) is the conductivity and \( \hat{e}_{ij} \) is a matrix (2 \( \times \) 2 for two dimensions and 3 \( \times \) 3 for three-dimensional problems). Note that \( \hat{e}_{ij} \) can be a non-symmetric matrix.

To define anisotropic thermal conductivity for a solid material, select anisotropic for Thermal Conductivity in the Create/Edit Materials Dialog Box (p. 2022) (Figure 7.19: The Create/Edit Materials Dialog Box (p. 435)). Note that this option is appropriate when the components of the \( k_{ij} \) matrix are constants and do not vary independently; if this is not the case, you can use a UDF to define the matrix and select user-defined-anisotropic-k, as described in User-Defined Anisotropic Thermal Conductivity (p. 443).

Selecting anisotropic opens the Anisotropic Conductivity Dialog Box (p. 2049) (Figure 7.20: The Anisotropic Conductivity Dialog Box (p. 439)).
In the Anisotropic Conductivity Dialog Box (p. 2049), enter the Matrix Components of matrix $\hat{e}_{ij}$ and then select the Conductivity ($k$ in Equation 7.51 (p. 438)) to be a constant, polynomial function of temperature (polynomial, piecewise-linear, piecewise-polynomial), or user-defined function. See Constant Thermal Conductivity (p. 435) and Thermal Conductivity as a Function of Temperature (p. 435) for details on constants and thermal polynomial functions.

When you select the user-defined option, the User-Defined Functions Dialog Box (p. 2039) will open allowing you to hook a DEFINE_PROPERTY UDF only if you have previously loaded a compiled UDF library or interpreted the UDF. Otherwise, you will get an error message. Details about user-defined functions can be found in the UDF Manual.

### 7.5.5.2. Biaxial Thermal Conductivity

Biaxial thermal conductivity is applicable only for solid materials used for the wall shell conduction model. To define a biaxial thermal conductivity, select biaxial in the drop-down list for Thermal Conductivity in the Create/Edit Materials Dialog Box (p. 2022). This opens the Biaxial Conductivity Dialog Box (p. 2045) (Figure 7.21: The Biaxial Conductivity Dialog Box (p. 440)).
In the Biaxial Conductivity Dialog Box (p. 2045), both the conductivity normal to the surface of the shell (Transverse Conductivity) and the conductivity parallel to the surface of the shell (Planar Conductivity) can be defined as constant, polynomial, piecewise-linear, or piecewise-polynomial. See Constant Thermal Conductivity (p. 435) and Thermal Conductivity as a Function of Temperature (p. 435) for details on these parameters. Note that the Planar Conductivity is isotropic. See Figure 13.6: The Shell Conduction Manager Dialog Box (p. 773).

### 7.5.5.3. Orthotropic Thermal Conductivity

When the orthotropic thermal conductivity is used, the thermal conductivities \( k_\xi, k_\eta, k_\zeta \) in the principal directions \( \left( \hat{e}_\xi, \hat{e}_\eta, \hat{e}_\zeta \right) \) are specified. The conductivity matrix is then computed as

\[
k_{ij} = k_\xi \hat{e}_\xi \cdot \hat{e}_\xi + k_\eta \hat{e}_\eta \cdot \hat{e}_\eta + k_\zeta \hat{e}_\zeta \cdot \hat{e}_\zeta
\]  

(7.52)

To define an orthotropic thermal conductivity in solids, select orthotropic in the drop-down list for Thermal Conductivity in the Create/Edit Materials Dialog Box (p. 2022). This opens the Orthotropic Conductivity Dialog Box (p. 2048) (Figure 7.22: The Orthotropic Conductivity Dialog Box (p. 441)).
Figure 7.22: The Orthotropic Conductivity Dialog Box

Since the directions \((\hat{e}_\xi, \hat{e}_\eta, \hat{e}_\zeta)\) are mutually orthogonal, only the first two need to be specified for three-dimensional problems. \(\hat{e}_\xi\) is defined using \(X, Y, Z\) under Direction 0 Components, and \(\hat{e}_\eta\) is defined using \(X, Y, Z\) under Direction 1 Components. You can define Conductivity 0 \((k_\xi)\), Conductivity 1 \((k_\eta)\), and Conductivity 2 \((k_\zeta)\) as constant, polynomial, piecewise-linear, piecewise-polynomial functions of temperature, or user-defined. See Constant Thermal Conductivity (p. 435) and Thermal Conductivity as a Function of Temperature (p. 435) for details on constant and temperature profile functions.

When you select the user-defined option, the User-Defined Functions Dialog Box (p. 2039) will open allowing you to hook a DEFINE_PROPERTY UDF only if you have previously loaded a compiled UDF library or interpreted the UDF. Otherwise, you will get an error message. More information about user-defined functions can be found in the UDF Manual.

Important

For two-dimensional problems, only the functions \((k_\xi, k_\eta)\) and the unit vector \((\hat{e}_\xi)\) need to be specified.
7.5.5.4. Cylindrical Orthotropic Thermal Conductivity

The orthotropic conductivity of solids can be specified in cylindrical coordinates. To define the orthotropic thermal conductivity in cylindrical coordinates, select **cyl-orthotropic** in the drop-down list for **Thermal Conductivity** in the Create/Edit Materials Dialog Box (p. 2022). This opens the Cylindrical Orthotropic Conductivity Dialog Box (p. 2046) (Figure 7.23: The Cylindrical Orthotropic Conductivity Dialog Box(p. 442)).

![Cylindrical Orthotropic Conductivity Dialog Box](image)

In three-dimensional cases, the origin and the direction of the cylindrical coordinate system must be specified along with the radial, tangential, and axial direction conductivities. In two-dimensional cases, the origin of the cylindrical coordinate system must be specified along with the radial and tangential direction conductivities. Note that in two-dimensional cases, the direction is always along the +z axis. ANSYS Fluent will automatically compute the anisotropic conductivity matrix at each cell from this input. The calculation is based on the location of the cell in the cylindrical coordinate system specified.

You can define the **Radial Conductivity**, **Tangential Conductivity**, and **Axial Conductivity** as **constant**, **polynomial**, **piecewise-linear**, **piecewise-polynomial**, or as user-defined functions of temperature. See Constant Thermal Conductivity (p. 435) and Thermal Conductivity as a Function of Temperature (p. 435) for details on constant and thermal profile functions.

When you select the **user-defined** option, the User-Defined Functions Dialog Box (p. 2039) will open allowing you to hook a DEFINE_PROPERTY UDF only if you have previously loaded a compiled UDF.
library or interpreted the UDF. Otherwise, you will get an error message. More information about user-defined functions can be found in the UDF Manual.

**Important**

For conductivity calculations near the wall, the cell next to the wall is chosen for computing the conductivity matrix instead of the wall itself.

### 7.5.5.5. User-Defined Anisotropic Thermal Conductivity

You have the option of modeling anisotropic conduction for domains where the components of the thermal conductivity matrix \( k_{ij} \) in Equation 7.51 (p. 438) are not constants and vary independently, perhaps as a function of space or because the domain has many anisotropic materials stitched together to form a composite. To use this option, you must first define the conductivity matrix using a UDF, as described in `DEFINE_ANISOTROPIC_CONDUCTIVITY` in the UDF Manual.

After you have interpreted or compiled the `DEFINE_ANISOTROPIC_CONDUCTIVITY` UDF, you must then select `user-defined-anisotropic-k` for Thermal Conductivity in the Create/Edit Materials Dialog Box (p. 2022). This will open the User-Defined Functions Dialog Box (p. 2039), which you can use to hook the UDF.

### 7.6. User-Defined Scalar (UDS) Diffusivity

There are two types of UDS diffusivity that you can specify in ANSYS Fluent: isotropic and anisotropic. Diffusion is isotropic when it is the same in all directions. Isotropic diffusion coefficients can be specified in two ways: either as a single user-defined that applies to all UDS transport equations defined for your model; or on a per-scalar basis as constants, polynomial functions of temperature, or user-defined functions.

Diffusion is anisotropic when the diffusion coefficients are different in different directions. Anisotropic diffusion can be specified by a tensor diffusion coefficient matrix \( \Gamma \) (Equation 7.53 (p. 443)) for each UDS (in both fluid and solid zones) in four different ways: general anisotropic, orthotropic, cyl-orthotropic, and user-defined-anisotropic. All UDS diffusivity parameters are set from the Create/Edit Materials Dialog Box (p. 2022) and are discussed below. Note that details about how to define and use UDFs in UDS transport equations is discussed in the UDF Manual.

The second-order diffusion term in the most general form is

\[
\nabla \cdot \left( \Gamma \cdot \nabla \phi \right) \tag{7.53}
\]

where \( \Gamma \) is a \( 3 \times 3 \) tensor in 3D.

For additional information, see the following sections:

- 7.6.1. Isotropic Diffusion
- 7.6.2. Anisotropic Diffusion
- 7.6.3. User-Defined Anisotropic Diffusivity

#### 7.6.1. Isotropic Diffusion

For isotropic diffusion, \( \Gamma \) in Equation 7.53 (p. 443) is equal to a scalar \( \Gamma \) times the identity matrix and the equation reduces to
You can specify isotropic diffusivity as a single user-defined function that applies to all UDS transport equations. For this case, choose **user-defined** from the drop-down list for **UDS Diffusivity** in the Create/Edit Materials Dialog Box (p. 2022).

**Materials**

If you have previously loaded a compiled UDF library or have interpreted the UDF, then the **User-Defined Functions Dialog Box** (p. 2039) will open, allowing you to hook the **DEFINE_DIFFUSIVITY** UDF to ANSYS Fluent. If no functions have been loaded, you will get an error message. More information about user-defined functions can be found in the **UDF Manual**.

Isotropic diffusion coefficients can also be defined on a per-scalar basis by selecting **defined-per-uds** from the drop-down list for **UDS Diffusivity** in the Create/Edit Materials Dialog Box (p. 2022). This will open the **UDS Diffusion Coefficients Dialog Box** (p. 2062) (Figure 7.24: The UDS Diffusion Coefficients Dialog Box).

**Figure 7.24: The UDS Diffusion Coefficients Dialog Box**

In the **UDS Diffusion Coefficients Dialog Box** (p. 2062), select a scalar equation (for example, **uds-0**) and then choose a **constant**, **polynomial**, or **user-defined** function from the **Coefficient** drop-down list. For the default fluid (air), the constant diffusion coefficient is 1 kg/m·s. If you choose **polynomial**, the **Polynomial Profile Dialog Box** (p. 2036) will open and you can specify your coefficients as a function of temperature. See **Inputs for Polynomial Functions** (p. 412) for details.

When you select the **user-defined** option, the **User-Defined Functions Dialog Box** (p. 2039) will open allowing you to hook a **DEFINE_DIFFUSIVITY** UDF only if you have previously loaded a compiled UDF library or interpreted a UDF. Otherwise, you will get an error message. More information about user-defined functions can be found in the **UDF Manual**.
7.6.2. Anisotropic Diffusion

You can specify anisotropic diffusion coefficients in both fluid and solid zones by defining the tensor diffusion coefficient matrix \( \Gamma \) (Equation 7.53 (p. 443)) on a per-scalar basis. You can use anisotropic diffusivity for UDS scalar transport equations to model species transport equations in porous media and in solids where species diffusion shows anisotropic behavior.

**Important**

- Note that the anisotropic diffusion options discussed in the following sections are available with the pressure-based solver and the density-based solvers.
- UDS diffusion coefficients can be postprocessed only in those cells that have isotropic diffusivity. In all other cells, the diffusion coefficient will be zero.

In all cases, you enable anisotropic diffusion by selecting **defined-per-uds** under **UDS Diffusivity** in the Create/Edit Materials Dialog Box (p. 2022). This will open the UDS Diffusion Coefficients Dialog Box (p. 2062) (Figure 7.24: The UDS Diffusion Coefficients Dialog Box (p. 444)).

**Materials**

In the UDS Diffusion Coefficients Dialog Box (p. 2062), select a scalar equation (for example, **uds-0**) and then choose one of the following methods under **Coefficient** to specify the anisotropic diffusion coefficient. These methods are described in detail below.

- anisotropic
- orthotropic
- cylindrical orthotropic
- user-defined anisotropic

### 7.6.2.1. Anisotropic Diffusivity

For anisotropic diffusivity, you can specify \( \Gamma \) in Equation 7.53 (p. 443) in the form \( K \Gamma \) where \( K \) is a constant \( 3 \times 3 \) matrix in 3D and \( \Gamma \) is a scalar multiplier.

The diffusion coefficient matrix is specified as

\[
\begin{align*}
 k_{ij} &= k \hat{e}_{ij} \\
(7.55)
\end{align*}
\]

where \( k \) is the diffusivity and \( \hat{e}_{ij} \) is a matrix (2 \times 2 for two dimensions and 3 \times 3 for three-dimensional problems). Note that \( \hat{e}_{ij} \) can be a non-symmetric matrix.

To specify anisotropic diffusion coefficients, first select a scalar equation (for example, **uds-0**) from the **User-Defined Scalar Diffusion** list in the UDS Diffusion Coefficients Dialog Box (p. 2062) (Figure 7.24: The UDS Diffusion Coefficients Dialog Box (p. 444)). Then choose **anisotropic** in the drop-down list under **Coefficient**. This will open the **Anisotropic UDS Diffusivity** dialog box (Figure 7.25: The Anisotropic UDS Diffusivity Dialog Box (p. 446)).
In the **Anisotropic UDS Diffusivity** dialog box, enter the **Matrix Components** and then select the **Diffusivity** to be a constant, polynomial function of temperature (polynomial, piecewise-linear, piecewise-polynomial), or user-defined. See Inputs for Polynomial Functions (p. 412), Inputs for Piecewise-Linear Functions (p. 413), and Inputs for Piecewise-Polynomial Functions (p. 415) for details on polynomial temperature functions.

When you select the **user-defined** option, the User-Defined Functions Dialog Box (p. 2039) will open allowing you to hook a DEFINE_DIFFUSIVITY UDF only if you have previously loaded a compiled UDF library or interpreted a UDF. Otherwise, you will get an error message. More information about user-defined functions can be found in the UDF Manual.

### 7.6.2.2. Orthotropic Diffusivity

For orthotropic diffusivity, you can specify \( \nabla \) in Equation 7.53 (p. 443) through ‘principal’ direction vectors and diffusion coefficients along these directions. ANSYS Fluent, in turn, computes \( \nabla \) from parameters that you supply. The principal directions are the same everywhere, but each of the directional diffusion coefficients can be specified as a constant, polynomial function of temperature, or through user-defined functions.

When orthotropic diffusivity is used, the diffusion coefficients \( \left( k_{\xi}, k_{\eta}, k_{\zeta} \right) \) in the principal directions \( \left( \hat{e}_{\xi}, \hat{e}_{\eta}, \hat{e}_{\zeta} \right) \) are specified. The diffusivity matrix is then computed as

\[
k_{ij} = k_{\xi} \hat{e}_{\xi i} \hat{e}_{\xi j} + k_{\eta} \hat{e}_{\eta i} \hat{e}_{\eta j} + k_{\zeta} \hat{e}_{\zeta i} \hat{e}_{\zeta j}
\]

For two-dimensional problems, only the functions \( \left( k_{\xi}, k_{\eta} \right) \) and the unit vector \( \left( \hat{e}_{\xi} \right) \) need to be specified.

To specify orthotropic diffusion coefficients, first select a scalar equation (for example, **uds-0**) from the **User-Defined Scalar Diffusion** list in the UDS Diffusion Coefficients Dialog Box (p. 2062) (Figure 7.24: The UDS Diffusion Coefficients Dialog Box (p. 444)). Then choose **orthotropic** in the drop-down list under...
**Coefficient.** This will open the Orthotropic UDS Diffusivity dialog box (Figure 7.26: The Orthotropic UDS Diffusivity Dialog Box (p. 447)).

**Figure 7.26: The Orthotropic UDS Diffusivity Dialog Box**

Since the directions \((\hat{e}_\zeta, \hat{e}_\eta, \hat{e}_\zeta)\) are mutually orthogonal, only the first two need to be specified for three-dimensional problems. \(\hat{e}_\zeta\) is defined using \(X,Y,Z\) under **Direction 0 Components**, and \(\hat{e}_\eta\) is defined using \(X,Y,Z\) under **Direction 1 Components**. You can define **Diffusivity 0** \(\left( k_{\zeta} \right)\), **Diffusivity 1** \(\left( k_{\eta} \right)\), and **Diffusivity 2** \(\left( k_{\zeta} \right)\) as constant, polynomial, piecewise-linear, piecewise-polynomial functions of temperature, or **user-defined**. See Inputs for Polynomial Functions (p. 412), Inputs for Piecewise-Linear Functions (p. 413), and Inputs for Piecewise-Polynomial Functions (p. 415) for details on polynomial temperature functions.

When you select the **user-defined** option, the User-Defined Functions Dialog Box (p. 2039) will open allowing you to hook a DEFINE_DIFFUSIVITY UDF only if you have previously loaded a compiled UDF library or interpreted a UDF. If no functions have been loaded, you will get an error message. More information about user-defined functions can be found in the UDF Manual.

**7.6.2.3. Cylindrical Orthotropic Diffusivity**

Orthotropic UDS diffusivity can also be specified on a per-scalar basis in cylindrical coordinates. This method is similar to orthotropic UDS diffusivity, except that the principal directions are specified as radial, tangential, and axial.

To specify cylindrical orthotropic diffusion coefficients, first select a scalar equation (for example, **uds-0**) from the User-Defined Scalar Diffusion list in the UDS Diffusion Coefficients Dialog Box (p. 2062) (Figure 7.24: The UDS Diffusion Coefficients Dialog Box (p. 444)). Then choose **cyl-orthotropic** in the drop-down list under **Coefficient**. This will open the Cylindrical Orthotropic UDS Diffusivity dialog box (Figure 7.27: The Cylindrical Orthotropic UDS Diffusivity Dialog Box (p. 448)).
In three-dimensional cases, the origin and the direction of the cylindrical coordinate system must be specified along with the radial, tangential, and axial direction conductivities. In two-dimensional cases, the origin of the cylindrical coordinate system must be specified along with the radial and tangential direction conductivities. Note that in two-dimensional cases, the direction is always along the +z axis. ANSYS Fluent will automatically compute the anisotropic diffusivity matrix at each cell from this input. The calculation is based on the location of the cell in the cylindrical coordinate system specified.

You can define the **Radial Diffusivity**, **Tangential Diffusivity**, and **Axial Diffusivity** as **constant**, **polynomial**, **piecewise-linear**, **piecewise-polynomial**, or as **user-defined** functions of temperature, using the drop-down list below each of the diffusivities. See **Inputs for Polynomial Functions** (p. 412), **Inputs for Piecewise-Linear Functions** (p. 413), and **Inputs for Piecewise-Polynomial Functions** (p. 415) for details on polynomial temperature functions.

When you select the **user-defined** option, the **User-Defined Functions Dialog Box** (p. 2039) will open allowing you to hook a **DEFINE_DIFFUSIVITY** UDF only if you have previously loaded a compiled UDF library or interpreted a UDF. If no functions have been loaded, you will get an error message. More information about user-defined functions can be found in the **UDF Manual**.

### 7.6.3. User-Defined Anisotropic Diffusivity

You can specify \( \Gamma \) in **Equation 7.53** (p. 443) on a per-scalar basis, directly, through user-defined functions (UDFs).

To specify a UDF for anisotropic diffusivity on a per-scalar basis, first select a scalar equation (for example, **uds-0**) from the **User-Defined Scalar Diffusion** list in the **UDS Diffusion Coefficients Dialog Box** (p. 2062) (Figure 7.28: The **UDS Diffusion Coefficients Dialog Box** (p. 449)).
Then choose **user-defined-anisotropic** in the drop-down list under **Coefficient**. The **User-Defined Functions Dialog Box** (p. 2039) will open allowing you to hook a DEFINE_ANISOTROPIC_DIFFUSIVITY UDF only if you have previously loaded a compiled UDF library or interpreted a UDF. Otherwise, you will get an error message. More information about user-defined functions can be found in the **UDF Manual**.

### 7.7. Specific Heat Capacity

The specific heat capacity must be defined when the energy equation is active. ANSYS Fluent provides several options for definition of the heat capacity:

- constant heat capacity
- temperature- and/or composition-dependent heat capacity
- kinetic theory

Each of these input options and the governing physical models are detailed in this section. In all cases, you will define the \( C_p \) in the **Create/Edit Materials Dialog Box** (p. 2022).

**Important**

For combustion applications, a temperature-dependent specific heat is recommended.

For additional information, see the following sections:

- 7.7.1. Input of Constant Specific Heat Capacity
- 7.7.2. Specific Heat Capacity as a Function of Temperature
- 7.7.3. Defining Specific Heat Capacity Using Kinetic Theory
### 7.7.4. Specific Heat Capacity as a Function of Composition

#### 7.7.1. Input of Constant Specific Heat Capacity

If you want to define the heat capacity as a constant, check that **constant** is selected in the drop-down list to the right of **Cp** in the **Create/Edit Materials Dialog Box (p. 2022)**, and enter the value of heat capacity.

The specific heat for the default fluid (air) is 1006.43 J/kg-K.

#### 7.7.2. Specific Heat Capacity as a Function of Temperature

You can also choose to define the specific heat capacity as a function of temperature. Three types of functions are available:

- **piecewise-linear:**
  \[
  c_p(T) = c_{p_n} + \frac{c_{p_{n+1}} - c_{p_n}}{T_{n+1} - T_n} (T - T_n)
  \] (7.57)

- **piecewise-polynomial:**

  For \( T_{min,1} \leq T < T_{max,1} \):
  \[
  c_p(T) = A_1 + A_2 T + A_3 T^2 + \ldots
  \] (7.58)

  For \( T_{min,2} \leq T < T_{max,2} \):
  \[
  c_p(T) = B_1 + B_2 T + B_3 T^2 + \ldots
  \]

- **polynomial:**

  \[
  c_p(T) = A_1 + A_2 T + A_3 T^2 + \ldots
  \] (7.59)

You can input the data pairs \((T_n, c_{p_n})\), ranges and coefficients \(A_i\) and \(B_i\) or coefficients \(A_i\) that describe these functions using the **Create/Edit Materials Dialog Box (p. 2022)**, as described in **Defining Properties Using Temperature-Dependent Functions (p. 412)**.

#### 7.7.3. Defining Specific Heat Capacity Using Kinetic Theory

If you are using the ideal gas law (as described in **Density (p. 416)**), you have the option to define the specific heat capacity using kinetic theory as

\[
 c_{p,i} = \frac{1}{2} \frac{R}{M_{W,i}} (f_i + 2)
 \] (7.60)

where \(f_i\) is the number of modes of energy storage (degrees of freedom) for the gas species \(i\) that you can input by selecting **kinetic-theory** from the drop-down list to the right of **Cp** in the **Create/Edit Materials Dialog Box (p. 2022)**. The solver will use your kinetic theory inputs in **Equation 7.60 (p. 450)** to compute the specific heat capacity. See **Kinetic Theory Parameters (p. 465)** for details about kinetic theory inputs.

#### 7.7.4. Specific Heat Capacity as a Function of Composition

If you are modeling a flow that includes more than one chemical species (multicomponent flow), you have the option to define a composition-dependent specific heat capacity. You can also define the heat capacity of the mixture as a constant value or a function of temperature, or using kinetic theory.
To define a composition-dependent specific heat capacity for a mixture, follow these steps:

1. For the mixture material, choose mixing-law in the drop-down list to the right of \( \text{Cp} \).

2. Click Change/Create.

3. Define the specific heat capacity for each of the fluid materials that comprise the mixture. You may define constant or (if applicable) temperature-dependent heat capacities for the individual species. You may also use kinetic theory for the individual heat capacities, if applicable.

The solver will compute the mixture's specific heat capacity as a mass fraction average of the pure species heat capacities:

\[
\overline{c_p} = \sum_i Y_i c_{p,i}
\]  

(7.61)

7.8. Radiation Properties

When you have activated one of the radiation models (except for the surface-to-surface model, which requires no additional properties), there will be additional properties for you to set in the Create/Edit Materials Dialog Box (p. 2022):

• For the P-1 model, you must set the radiation Absorption Coefficient and Scattering Coefficient \((a \text{ and } \sigma_s)\) in Equation 5.18 in the Theory Guide).

• For the Rosseland radiation model, you will also need to set the Absorption Coefficient and Scattering Coefficient \((a \text{ and } \sigma_s)\) in Equation 5.19 in the Theory Guide).

• For the DTRM, only the Absorption Coefficient is required \((a)\) in Equation 5.52 in the Theory Guide).

• For the DO model set both, the Absorption Coefficient and the Scattering Coefficient \((a \text{ and } \sigma_s)\) in Equation 5.59 in the Theory Guide). In addition, if you are modeling semi-transparent media, specify the Refractive Index \((n_a \text{ or } n_s)\) in Equation 5.78 in the Theory Guide). With the DO model, you can specify radiation properties for solid materials, to be used when semi-transparent media are modeled.

For additional information, see the following sections:

7.8.1. Absorption Coefficient
7.8.2. Scattering Coefficient
7.8.3. Refractive Index
7.8.4. Reporting the Radiation Properties

7.8.1. Absorption Coefficient

To define the absorption coefficient, you can specify a constant value, a temperature-dependent function (see Defining Properties Using Temperature-Dependent Functions (p. 412)), a composition-dependent function, or a user-defined function. The absorbing and emitting parts of the radiative transfer equation (RTE), Equation 5.17 in the Theory Guide, is a function of the absorption coefficient. The absorbing or emitting effects depend on the chosen radiation model. If there are only absorption effects, then Lambert's Law of absorption applies

\[
I = I_0 \exp (-ax)
\]  

(7.62)

where \( I \) is the radiation intensity, \( a \) is the absorption coefficient, and \( x \) is the distance through the material.
If you are modeling non-gray radiation with the P-1 or the DO radiation model, you also have the option to specify a constant absorption coefficient in each of the gray bands. The absorption coefficient is requested in units of 1/length. Along with the scattering coefficient, it describes the change in radiation intensity per unit length along the path through the fluid medium. Absorption coefficients can be computed using tables of emissivity for CO$_2$ and H$_2$O, which are generally available in textbooks on radiation heat transfer.

### 7.8.1.1. Inputs for a Constant Absorption Coefficient

To define a constant absorption coefficient, simply enter the value in the field next to **Absorption Coefficient** in the *Create/Edit Materials Dialog Box* (p. 2022). Select **constant** in the drop-down list first if it is not already selected.

### 7.8.1.2. Inputs for a Composition-Dependent Absorption Coefficient

ANSYS Fluent also allows you to input a composition-dependent absorption coefficient, where the local value of $\alpha$ is a function of the local mass fractions of water vapor and carbon dioxide. This modeling option can be useful for the simulation of radiation in combustion applications. The variable-absorption-coefficient model used by ANSYS Fluent is the weighted-sum-of-gray-gases model (WSGGM) described in *Radiation in Combusting Flows* in the *Theory Guide*. To activate it, first enable the species calculation and make sure that CO$_2$ and H$_2$O are present in the mixture. Next, select **wsggm-domain-based**, **wsggm-user-specified**, or **user-defined-wsggm** in the drop-down list to the right of **Absorption Coefficient** in the *Create/Edit Materials* dialog box. If you select **user-defined-wsggm**, the **User-Defined Functions** dialog box will open, allowing you to select a previously loaded compiled UDF library or a previously interpreted UDF (see *Hooking DEFINE_WSGGM_ABS_COEFF UDFs in the UDF Manual*). The WSGGM options differ in the method used to compute the path length, as described in the section that follows.

#### 7.8.1.2.1. Path Length Inputs

When the WSGGM is used to compute the absorption coefficient, you can choose how path length, $s$, is defined for *Equation 5.106* in the *Theory Guide*. See *Radiation in Combusting Flows* in the *Theory Guide* to determine which method is appropriate for your case.

You will select the path length method when you choose the property input method for **Absorption Coefficient**, as described previously.

- If you choose **wsggm-domain-based**, $s$ is set equal to a mean beam length calculated by ANSYS Fluent according to *Equation 5.107* in the *Theory Guide*, which is an average dimension of the domain; no further inputs are required.

- If you choose **wsggm-user-specified**, $s$ is set equal to a mean beam length that you enter for **Path Length** in the *WSGGM User Specified Dialog Box* (p. 2063).

- If you choose **user-defined-wsggm**, ANSYS Fluent will initially compute the absorption coefficient in the same manner as described for the **wsggm-domain-based** option; however, you have the option of writing a user-defined function that customizes this calculated value. If the soot model is enabled, you can also use the UDF to customize the soot absorption coefficient computed by ANSYS Fluent. See **DEFINE_WSGGM_ABS_COEFF** in the *UDF Manual* for further details.
7.8.1.2.1.1. Inputs for a Non-Gray Radiation Absorption Coefficient

If you are using the non-gray DO model (see The DO Model Equations of the Theory Guide and Defining Non-Gray Radiation for the DO Model (p. 795)) or the non-gray P-1 model (see The P-1 Model Equations of the Theory Guide and Setting Up the P-1 Model with Non-Gray Radiation (p. 779)), you can specify a different constant absorption coefficient for each of the bands used by the gray-band model. Select gray-band from the Absorption Coefficient drop-down list in the Create/Edit Materials dialog box and then define the absorption coefficient for each band in the Gray-Band Absorption Coefficient Dialog Box (p. 2064). (Note that you must complete this dialog box in order to proceed.)

7.8.1.2.1.2. Effect of Particles and Soot on the Absorption Coefficient

ANSYS Fluent will include the effect of particles on the absorption coefficient if you have turned on the Particle Radiation Interaction option in the Discrete Phase Model Dialog Box (p. 1998) (only for the P-1 and DO radiation models).

If you are modeling soot formation and you want to include the effect of soot formation on the absorption coefficient, turn on the Soot-Radiation Interaction in the Soot Model Dialog Box (p. 1985). The soot effects can be included for any of the radiation models, as long as you are using the WSGGM to compute a composition-dependent absorption coefficient. Note that you can use the user-defined-wsggm option to customize the soot absorption coefficient calculated by ANSYS Fluent, as described previously.

7.8.2. Scattering Coefficient

The scattering coefficient is, by default, set to zero, and it is assumed to be isotropic. You can specify a constant value, a temperature-dependent function (see Defining Properties Using Temperature-Dependent Functions (p. 412)), or a user-defined function. You can also specify a non-isotropic phase function.

The scattering coefficient is requested in units of 1/length. Along with the absorption coefficient, it describes the change in radiation intensity per unit length along the path through the fluid medium. You may want to increase the scattering coefficient in combustion systems, where particulates may be present.

7.8.2.1. Inputs for a Constant Scattering Coefficient

To define a constant scattering coefficient, simply enter the value in the field next to Scattering Coefficient in the Create/Edit Materials Dialog Box (p. 2022). (Select constant in the drop-down list first if it is not already selected.)

7.8.2.2. Inputs for the Scattering Phase Function

Scattering is assumed to be isotropic, by default, but you can also specify a linear-anisotropic scattering function. If you are using the DO model, Delta-Eddington and user-defined scattering functions are also available.

7.8.2.2.1. Isotropic Phase Function

To model isotropic scattering, select isotropic in the Scattering Phase Function drop-down list. No further inputs are necessary. This is the default setting in ANSYS Fluent.
7.8.2.2.2. Linear-Anisotropic Phase Function

To model anisotropic scattering, select linear-anisotropic in the Scattering Phase Function drop-down list and set the value of the phase function coefficient \( C \) in Equation 5.19 in the Theory Guide.

7.8.2.2.3. Delta-Eddington Phase Function

To use a Delta-Eddington phase function, select delta-eddington in the Scattering Phase Function drop-down list. This will open the Delta-Eddington Scattering Function Dialog Box (p. 2064), in which you can specify the Forward Scattering Factor and Asymmetry Factor \( f \) and \( C \) in Equation 5.68 in the Theory Guide. Since this is a modal dialog box, you must tend to it immediately.

7.8.2.2.4. User-Defined Phase Function

To use a user-defined phase function, select user-defined in the Scattering Phase Function drop-down list. The user-defined function will contain specifications for \( \Phi^* \) and \( f \) in Equation 5.69 in the Theory Guide. More information about user-defined functions can be found in the UDF Manual.

7.8.3. Refractive Index

The refractive index is the ratio of speed of light in the medium to the speed of light in vacuum. It is by default set to 1. You can specify a constant value in the field next to Refractive Index.

If you are using the non-gray DO model (see The DO Model Equations of the Theory Guide and Defining Non-Gray Radiation for the DO Model (p. 795)) or the non-gray P-1 model (see The P-1 Model Equations of the Theory Guide and Setting Up the P-1 Model with Non-Gray Radiation (p. 779)), you can specify a different constant refractive index for each of the bands used by the gray-band model. Select refractive-band from the Refractive Index drop-down list in the Create/Edit Materials dialog box and then define the refractive index for each band in the Gray-Band Refractive Index Dialog Box (p. 2065). Note that because this is a modal dialog box, you must tend to it immediately.

7.8.4. Reporting the Radiation Properties

You can display the computed local values for \( a \) and \( \sigma_s \) using the Absorption Coefficient and Scattering Coefficient items in the Radiation... category of the variable selection drop-down list that appears in postprocessing dialog boxes. You will also find the Refractive Index in the Radiation... category.

7.9. Mass Diffusion Coefficients

For species transport calculations, there are two ways to model the diffusion of chemical species. For most applications the Fick’s law approximation is adequate, but for some applications (for example, diffusion-dominated laminar flows such as chemical vapor deposition), the full multicomponent diffusion model is recommended.

---

**Important**

The full multicomponent diffusion model is enabled in the Species Model Dialog Box (p. 1943) and is computationally expensive.

---

For additional information, see the following sections:

* 7.9.1. Fickian Diffusion
7.9.1. Fickian Diffusion

Mass diffusion coefficients are required whenever you are solving species transport equations in multicomponent flows. Mass diffusion coefficients are used to compute the diffusion flux of a chemical species in a laminar flow using (by default) Fick’s law:

\[ J_i = -\rho D_{i,m} \nabla Y_i - D_{T,i} \frac{\nabla T}{T} \]  (7.63)

where \( D_{i,m} \) is the mass diffusion coefficient for species \( i \) in the mixture and \( D_{T,i} \) is the thermal (Soret) diffusion coefficient.

Equation 7.63 (p. 455) is strictly valid when the mixture composition is not changing, or when \( D_{i,m} \) is independent of composition. This is an acceptable approximation in dilute mixtures when \( Y_j << 1 \) for all \( j \) except the carrier gas. ANSYS Fluent can also compute the transport of non-dilute mixtures in laminar flows by treating such mixtures as multicomponent systems. Within ANSYS Fluent, \( D_{i,m} \) can be specified in a variety of ways, including by specifying \( D_{ij} \) the binary mass diffusion coefficient of component \( j \) in component \( i \). \( D_{ij} \) is not used directly, however; instead, the diffusion coefficient in the mixture, \( D_{i,m} \), is computed as

\[ D_{i,m} = \sum_{j \neq i} \left( X_i / D_{ij} \right) \left( 1 - X_i \right) \]  (7.64)

where \( X_i \) is the mole fraction of species \( i \). You can input \( D_{i,m} \) or \( D_{ij} \) for each chemical species, as described in Mass Diffusion Coefficient Inputs (p. 460).

In turbulent flows, Equation 7.63 (p. 455) is replaced with the following form:

\[ J_i = -\left( \rho D_{i,m} + \frac{\mu}{S_c} \right) \nabla Y_i - D_{T,i} \frac{\nabla T}{T} \]  (7.65)

where \( S_c \) is the effective Schmidt number for the turbulent flow:

\[ S_c = \frac{\mu}{\rho D_i} \]  (7.66)

and \( D_i \) is the effective mass diffusion coefficient due to turbulence.

In turbulent flows your mass diffusion coefficient inputs consist of defining the molecular contribution to diffusion \( D_{i,m} \) using the same methods available for the laminar case, with the added option to alter the default settings for the turbulent Schmidt number. As seen from Equation 7.66 (p. 455), this parameter relates the effective mass diffusion coefficient due to turbulence with the eddy viscosity \( \mu_T \). As discussed in Mass Diffusion Coefficient Inputs for Turbulent Flow (p. 463), the turbulent diffusion coefficient normally
overwhelms the laminar diffusion coefficient, so the default constant value for the laminar diffusion coefficient is usually acceptable.

7.9.2. Full Multicomponent Diffusion

A careful treatment of chemical species diffusion in the species transport and energy equations is important when details of the molecular transport processes are significant (for example, in diffusion-dominated laminar flows). As one of the laminar-flow diffusion models, ANSYS Fluent has the ability to model full multicomponent species transport.

7.9.2.1. General Theory

For multicomponent systems it is not possible, in general, to derive relations for the diffusion fluxes containing the gradient of only one component (as described in Fickian Diffusion (p. 455)). Here, the Maxwell-Stefan equations will be used to obtain the diffusive mass flux. This will lead to the definition of generalized Fick’s law diffusion coefficients \[ (106) \] (p. 2562). This method is preferred over computing the multicomponent diffusion coefficients since their evaluation requires the computation of \( N^2 \) cofactor determinants of size \( (N-1) \times (N-1) \), and one determinant of size \( N \times N \) \[ (100) \] (p. 2562), where \( N \) is the number of chemical species.

7.9.2.2. Maxwell-Stefan Equations

From Merk \[ (61) \] (p. 2560), the Maxwell-Stefan equations can be written as

\[
\sum_{j \neq i}^{N} X_i X_j \left( \overline{V}_j - \overline{V}_i \right) = \overline{d}_i - \frac{\nabla T}{T} \sum_{j \neq i}^{N} X_i X_j \left( \frac{D_{T,i,j} - D_{T,i}}{\rho_j} \right) \quad (7.67)
\]

where,

- \( X = \) the mole fraction
- \( \overline{V} = \) the diffusion velocity
- \( D_{ij} = \) the binary mass diffusion coefficient of species \( i \) in species \( j \)
- \( D_T = \) the thermal diffusion coefficient.

For an ideal gas the Maxwell diffusion coefficients are equal to the binary diffusion coefficients. If the external force is assumed to be the same on all species and that pressure diffusion is negligible, then \( \overline{d}_i = \nabla X_i \). Since the diffusive mass flux vector is \( \overline{J}_i = \rho_i \overline{V}_i \), the above equation can be written as

\[
\sum_{j \neq i}^{N} X_i X_j \left( \frac{\overline{J}_j}{\rho_j} - \frac{\overline{J}_i}{\rho_i} \right) = \nabla X_i - \frac{\nabla T}{T} \sum_{j \neq i}^{N} X_i X_j \left( \frac{D_{T,i,j} - D_{T,i}}{\rho_j} \right) \quad (7.68)
\]

After some mathematical manipulations, the diffusive mass flux vector, \( \overline{J}_i \), can be obtained from

\[
\overline{J}_i = - \sum_{j=1}^{N-1} \rho j_D j \nabla Y_j - D_{T,i} \frac{\nabla T}{T} \quad (7.69)
\]

where \( Y_j \) is the mass fraction of species \( j \). Other terms are defined as follows:
\[ D_{ij} = [D] = [A]^{-1} [B] \]

\[ M_{w,m} = \left( \sum_{i=1}^{N} \frac{Y_i}{M_{w,i}} \right) \]

\[ A_{ii} = - \left( \frac{X_i M_{w,m}}{\mathcal{D}_{iN} M_{w,N}} + \sum_{j=1}^{N} \frac{X_j M_{w,m}}{\mathcal{D}_{ij} M_{w,i}} \right) \]

\[ A_{ij} = X_i \left( \frac{1}{\mathcal{D}_{ij}} \frac{M_{w,m}}{M_{w,j}} - \frac{1}{\mathcal{D}_{iN}} \frac{M_{w,m}}{M_{w,N}} \right) \]

\[ B_{ii} = - \left( X_i \frac{M_{w,m}}{M_{w,N}} + (1-X_i) \frac{M_{w,m}}{M_{w,i}} \right) \]

\[ B_{ij} = X_i \left( \frac{M_{w,m}}{M_{w,j}} - \frac{M_{w,m}}{M_{w,N}} \right) \]

where,

\([A]\) and \([B]\) = \((N - 1) \times (N - 1)\) matrices

\([D]\) = an \((N - 1) \times (N - 1)\) matrix of the generalized Fick’s law diffusion coefficients

\[ D_{ij} \] \[106\] (p. 2562)

\(M_w\) = the molecular weight

\(m\) = a subscript used to define a mean molecular weight in the mixture

### 7.9.3. Anisotropic Species Diffusion

You can model anisotropic species diffusion in porous media.

For Fickian diffusion, the mass flux vector of species \(i\) is modeled as,

\[ J_i = -\varepsilon (\rho D_{i,m} + \frac{\mu_i}{S_{Ci}}) \nabla Y_i - (1-\varepsilon) (\rho D_{i,m} + \frac{\mu_i}{S_{Ci}}) K \nabla Y_i - DT \frac{\nabla T}{T} \] \(7.71\)

where \(\varepsilon\) is the porosity, \(K\) is the anisotropic diffusion matrix in the porous zone, and the remaining nomenclature is the same as in Equation 7.65 (p. 455).

The Full Multi-component (Maxwell-Stefan) anisotropic diffusion flux vector is calculated similar to Equation 7.69 (p. 456) as,

\[ J_i = -\varepsilon \sum_{j=1}^{N} \rho D_{ij} \nabla Y_j - (1-\varepsilon) \sum_{j=1}^{N} \rho D_{ij} K \nabla Y_j - DT \frac{\nabla T}{T} \] \(7.72\)

To account for anisotropic species diffusion in porous media simulations, select the **Anisotropic Species Diffusion** check box in the **Porous Zone** tab of the **Fluid** dialog box and specify the **Matrix Components** for the anisotropic diffusion matrix \(K\) (see Figure 7.29: Anisotropic Species Diffusion Matrix (p. 458)).
By default, $\mathbf{K}$ is the identity matrix which corresponds to isotropic diffusion.

### 7.9.4. Thermal Diffusion Coefficients

The thermal diffusion coefficients can be defined as constants, polynomial functions, user-defined functions, or using the following empirically-based composition-dependent expression derived from [47] (p. 2559):

$$
D_{T,i} = -2.59 \times 10^{-7} T^{0.659} \left[ \frac{M_{w,i}^{0.511} X_i}{\sum_{i=1}^{N} M_{w,i}^{0.511} X_i} - Y_i \right] \cdot \left[ \frac{\sum_{i=1}^{N} M_{w,i}^{0.511} X_i}{\sum_{i=1}^{N} M_{w,i}^{0.489} X_i} \right] 
$$

(7.73)

This form of the Soret diffusion coefficient will cause heavy molecules to diffuse less rapidly, and light molecules to diffuse more rapidly, towards heated surfaces.

### 7.9.4.1. Thermal Diffusion Coefficient Inputs

If you have enabled thermal diffusion (in the Species Model Dialog Box (p. 1943)), you can define the thermal diffusion coefficients in the Create/Edit Materials Dialog Box (p. 2022) as follows:
1. **Select one of the following three methods in the drop-down list to the right of Thermal Diffusion Coefficient:**

   - **Choose kinetic-theory** to have ANSYS Fluent compute the thermal diffusion coefficients using the empirically-based expression in Equation 7.73 (p. 458). No further inputs are required for this option.

   - **Choose specified** to input the coefficient for each species. The Thermal Diffusion Coefficients Dialog Box (p. 2062) (Figure 7.30: The Thermal Diffusion Coefficients Dialog Box (p. 459)) will open. Further inputs are described in the step 2.

   - **Choose user-defined** to use a user-defined function. More information about user-defined functions can be found in the UDF Manual.

2. **(specified method only)** For each species in the Species Thermal Di list of the Thermal Diffusion Coefficients dialog box, perform the following steps:

   **Figure 7.30: The Thermal Diffusion Coefficients Dialog Box**

   ![Thermal Diffusion Coefficients Dialog Box]

   a. **Select** the species in the **Species Thermal Di** list for which you are going to define the thermal diffusion coefficient.

   b. **Define** $D_{T,i}$ for the selected species either as a constant value or as a polynomial function of temperature:

      - To define a constant diffusion coefficient, select **constant** (the default) in the drop-down list below **Coefficient**, and then enter the value in the field below the list.

      - To define a temperature-dependent diffusion coefficient, choose **polynomial** in the **Coefficient** drop-down list and then define the polynomial coefficients as described in Defining Properties Using Temperature-Dependent Functions (p. 412).
7.9.5. Mass Diffusion Coefficient Inputs

By default, the solver computes the species diffusion using Equation 7.63 (p. 455) (for laminar flows) with your inputs for \( D_{i,m} \), the diffusion coefficient for species \( i \) in the mixture. For turbulent flows, species diffusion is computed with Equation 7.65 (p. 455).

You can input the mass diffusion coefficients using one of the following methods:

- **Constant dilute approximation (Fickian diffusion only):** define one constant for all \( D_{i,m} \).

- **Dilute approximation (Fickian diffusion only):** define each \( D_{i,m} \) as a constant or as a polynomial function of temperature (if heat transfer is enabled).

- **Multicomponent method:** define the binary diffusion of species \( i \) in each species \( j \), \( D_{ij} \) as a constant or as a polynomial function of temperature, or (for ideal gases only) using kinetic theory.

- **Unity Lewis Number:** define \( D_{i,m} \) under the assumption of unity Lewis number for all species in the mixture.

- **User-defined function (UDF):** define a single function that will apply to all mass diffusion coefficients. This is done using the `DEFINE_DIFFUSIVITY` macro and is explained in the UDF Manual.

You should choose to input \( D_{i,m} \) (using one of the first two methods) if you are modeling a dilute mixture, with chemical species present at low mass fraction in a “carrier” fluid that is present at high concentration. You may want to define the individual binary mass diffusion coefficients, \( D_{ij} \), if you are modeling a non-dilute mixture. If you choose to define \( D_{ij} \), the solver will compute the diffusion of species \( i \) in the mixture using Equation 7.64 (p. 455), unless you have enabled full multicomponent diffusion.

The Lewis number is the ratio of thermal diffusivity (Prandtl number) to mass diffusivity (Schmidt number). Flames with non-unity Lewis number can display instabilities, as well as non-adiabatic flame temperatures. The Unity Lewis Number mass diffusivity option avoids these issues, and is particularly appropriate for the Thickened Flame model.

---

**Important**

If you want to use the full multicomponent diffusion model described in Full Multicomponent Diffusion (p. 456), turn on the Full Multicomponent Diffusion option in the Species Model Dialog Box (p. 1943), and then select the multicomponent diffusion model.

You will define \( D_{i,m} \) or \( D_{ij} \) for each chemical species using the Create/Edit Materials Dialog Box (p. 2022).

---

**Materials**

The diffusion coefficients have units of \( \text{m}^2/\text{s} \) in SI units or \( \text{ft}^2/\text{s} \) in British units.

### 7.9.5.1. Constant Dilute Approximation Inputs

To use the constant dilute approximation method, follow these steps:
1. Select **constant-dilute-appx** in the drop-down list to the right of **Mass Diffusivity**.

2. Enter a single value of $D_{i,m}$. The same value will be used for the diffusion coefficient of each species in the mixture.

### 7.9.5.2. Dilute Approximation Inputs

To use the dilute approximation method, follow the steps below:

1. Select **dilute-approx** in the drop-down list to the right of **Mass Diffusivity**.

2. In the resulting **Mass Diffusion Coefficients Dialog Box (p. 2060)** (Figure 7.31: The Mass Diffusion Coefficients Dialog Box for Dilute Approximation (p. 461)), select the species in the **Species Di** list for which you are going to define the mass diffusion coefficient.

**Figure 7.31: The Mass Diffusion Coefficients Dialog Box for Dilute Approximation**

3. You can define $D_{i,m}$ for the selected species either as a constant value or (if heat transfer is active) as a polynomial function of temperature:

   - To define a constant diffusion coefficient, select **constant** (the default) in the drop-down list below **Coefficient**, and then enter the value in the field below the list.

   - To define a temperature-dependent diffusion coefficient, choose **polynomial** in the **Coefficient** drop-down list and then define the polynomial coefficients as described in **Inputs for Polynomial Functions (p. 412)**.

   $D_{i,m} = A_1 + A_2 T + A_3 T^2 + \ldots$ \hspace{1cm} (7.74)

4. Repeat steps 2 and 3 until you have defined diffusion coefficients for all species in the **Species Di** list in the **Mass Diffusion Coefficients Dialog Box (p. 2060)**.
7.9.5.3. Multicomponent Method Inputs

To use the multicomponent method, and define constant or temperature-dependent diffusion coefficients, follow the steps below:

1. Select **multicomponent** in the drop-down list to the right of **Mass Diffusivity**.

2. In the resulting Mass Diffusion Coefficients Dialog Box (p. 2060) (Figure 7.32: The Mass Diffusion Coefficients Dialog Box for the Multicomponent Method (p. 462)), select the species in the **Species Di** list and the **Species Dj** list for which you are going to define the mass diffusion coefficient $D_{ij}$ for species $i$ in species $j$.

![Figure 7.32: The Mass Diffusion Coefficients Dialog Box for the Multicomponent Method](image)

3. You can define $D_{ij}$ for the selected pair of species as a constant value or as a polynomial function of temperature (if heat transfer is active).
   - To define a constant diffusion coefficient, select **constant** (the default) in the drop-down list below **Coefficient**, and then enter the value in the field below the list.
   - To define a temperature-dependent diffusion coefficient, choose **polynomial** in the **Coefficient** drop-down list and then define the polynomial coefficients as described in **Inputs for Polynomial Functions** (p. 412).
     \[
     D_{ij} = A_1 + A_2 T + A_3 T^2 + \ldots
     \] (7.75)

4. Repeat steps 2 and 3 until you have defined diffusion coefficients for all pairs of species in the **Species Di** and **Species Dj** lists in the Mass Diffusion Coefficients Dialog Box (p. 2060).

To use the multicomponent method, and define the diffusion coefficient using kinetic theory (available only when the ideal gas law is used), follow these steps:

1. Choose **kinetic-theory** in the drop-down list to the right of **Mass Diffusivity**.
2. Click **Change/Create** after completing other property definitions for the mixture material.

3. Define the Lennard-Jones parameters, \( \sigma_i \) and \( (\epsilon/k_B)_i \) for each species (fluid material), as described in **Kinetic Theory Parameters** (p. 465).

The solver will use a modification of the Chapman-Enskog formula \([57](p. 2560)\) to compute the diffusion coefficient using kinetic theory:

\[
D_{ij} = 0.00188 \left( \frac{T^3}{\frac{1}{M_{w,i}} + \frac{1}{M_{w,j}}} \right)^{1/2} \frac{p_{abs} \sigma_j^2 \Omega_D}{\rho} 
\]  

(7.76)

where,

\( p_{abs} \) is the absolute pressure

\( \Omega_D \) is the diffusion collision integral, which is a measure of the interaction of the molecules in the system

\( \Omega_D \) is a function of the quantity \( T^*_D \), where

\[
T^*_D = \frac{T}{(\epsilon/k_B)_i} 
\]

(7.77)

\( k_B \) is the Boltzmann constant, which is defined as the gas constant, \( R \), divided by Avogadro’s number.

\( (\epsilon/k_B)_i \) for the mixture is the geometric average:

\[
(\epsilon/k_B)_i = \sqrt{(\epsilon/k_B)_i(\epsilon/k_B)_j} 
\]

(7.78)

For a binary mixture, \( \sigma_{ij} \) is calculated as the arithmetic average of the individual \( \sigma \)s:

\[
\sigma_{ij} = \frac{1}{2}(\sigma_i + \sigma_j) 
\]

(7.79)

**7.9.5.4. Unity Lewis Number**

The laminar mass diffusivity of all species is calculated as:

\[
D_{i,m} = \frac{k}{\rho c_p} 
\]

where \( D_{i,m} \) denotes the mass diffusivity of species \( i \) in the mixture, \( k \) is the thermal conductivity, \( \rho \) is the mixture density, and \( c_p \) is the mixture specific heat.

**7.9.6. Mass Diffusion Coefficient Inputs for Turbulent Flow**

When your flow is turbulent, you will define \( D_{i,m} \) or \( D_{ij} \) as described for laminar flows in **Mass Diffusion Coefficient Inputs** (p. 460), and you will also have the option to alter the default setting for the turbulent Schmidt number, \( Sc_p \) as defined in Equation 7.66 (p. 455).
Usually, in a turbulent flow, the mass diffusion is dominated by the turbulent transport as determined by the turbulent Schmidt number (Equation 7.66 (p. 455)). The turbulent Schmidt number measures the relative diffusion of momentum and mass due to turbulence and is on the order of unity in all turbulent flows. Because the turbulent Schmidt number is an empirical constant that is relatively insensitive to the molecular fluid properties, you will have little reason to alter the default value (0.7) for any species.

Should you want to modify the Schmidt number, enter a new value for **Turb. Schmidt Number** in the **Viscous Model Dialog Box** (p. 1903).

![Models → Viscous → Edit...](image)

---

**Important**

Note that the full multicomponent diffusion model described in **Full Multicomponent Diffusion** (p. 456) is not recommended for turbulent flows.

### 7.10. Standard State Enthalpies

When you are solving a reacting flow using the finite-rate or eddy dissipation model, you must define the standard state enthalpy (also known as the formation enthalpy or heat of formation), $h^0_j$ for each species $j$. These inputs are used to define the mixture enthalpy as

$$
H = \sum_j Y_j \left[ \frac{h^0_j}{M_j} + \int_0^{T_{\text{ref},j}} C_{p,j} dT \right]
$$

(7.80)

where $M_j$ is the molecular weight of the $j^{th}$ species with units of kg/kmol and $T_{\text{ref},j}$ is the reference temperature at which $h^0_j$ is defined. Standard state enthalpies are input in units of J/kg mol in SI units or in units of Btu/ lbmol in British units.

For each species involved in the reaction (that is, each fluid material contained in the mixture material), you can set the **Standard State Enthalpy** and **Reference Temperature** in the **Create/Edit Materials Dialog Box** (p. 2022).

### 7.11. Standard State Entropies

If you are using the finite-rate model with reversible reactions (see **The Laminar Finite-Rate Model** in the **Theory Guide**), you must define the standard state entropy, $s^0_j$ for each species $j$. These inputs are used to define the mixture entropy as

$$
S = \sum_j Y_j \left[ \frac{s^0_j}{M_j} + \int_0^{T_{\text{ref},j}} \frac{C_{p,j}}{T} dT \right]
$$

(7.81)
where \( M_j \) is the molecular weight of the \( j^{th} \) species with units of kg/kmol and \( T_{\text{ref},j} \) is the reference temperature at which \( s_{\text{f},j}^0 \) is defined. Standard state entropies are input in units of J/kmol-K in SI units or in units of Btu/lbmol-°R in British units.

For each species involved in the reaction (that is, each fluid material contained in the mixture material), you can set the **Standard State Entropy** and **Reference Temperature** in the Create/Edit Materials Dialog Box (p. 2022).

### 7.12. Unburnt Thermal Diffusivity

If you are modeling premixed combustion (see **Modeling Premixed Combustion** (p. 1003)), the fluid material in your domain should be assigned the properties of the unburnt mixture, including the thermal diffusivity \( \alpha \) in Equation 9.9 in the *Theory Guide*. \( \alpha \) is defined as \( k/\rho c_{\text{p}} \) and values at standard conditions can be found in combustion handbooks (for example, [47] (p. 2559)). To determine values at non-standard conditions, you must use a third-party 1D combustion program with detailed chemistry. You can set the **Unburnt Thermal Diffusivity** in the Create/Edit Materials Dialog Box (p. 2022).

### 7.13. Kinetic Theory Parameters

You may choose to define the following properties using kinetic theory when the ideal gas law is enabled:

- viscosity (for fluids)
- thermal conductivity (for fluids)
- specific heat capacity (for fluids)
- mass diffusion coefficients (for multi-species mixtures)

If you are using kinetic theory for a fluid’s viscosity (Equation 7.26 (p. 428)), you must input the kinetic theory parameters \( \sigma \) and \( \varepsilon/k_B \) for that fluid. These parameters are the Lennard-Jones parameters and are referred to by ANSYS Fluent as the “characteristic length” and the “energy parameter” respectively.

- When kinetic theory is applied to calculation of a fluid’s thermal conductivity only, no inputs are required.
- To calculate specific heat of a fluid using kinetic theory (Equation 7.60 (p. 450)), you need to enter the degrees of freedom for the fluid material.
- If you use kinetic theory to define a mixture material’s mass diffusivity (Equation 7.76 (p. 463)), you must input \( \sigma_i \) and \( (\varepsilon/k_B)_i \) for each chemical species \( i \).

For additional information, see the following section:

#### 7.13.1. Inputs for Kinetic Theory

The procedure for using kinetic theory is as follows:

1. Select **kinetic-theory** as the property specification method for the **Viscosity**, **Thermal Conductivity**, or heat capacity **Cp** of a fluid material, or for the **Mass Diffusivity** of a mixture material.
2. If the material for which you have selected the kinetic theory method for one or more properties is a fluid material, you must set the kinetic theory parameters for each of the constituent species (fluid materials).

The parameters to be set are as follows:

- **L-J Characteristic Length**
- **L-J Energy Parameter**
- **Degrees of Freedom** (only required if kinetic theory is used for specific heat)

See the beginning of this section to find out which parameters are required to calculate each property using kinetic theory.

Characteristic length is defined in units of Angstroms. The energy parameter is defined in units of absolute temperature. Degrees of freedom is a dimensionless input. All kinetic theory materials can be found in the literature (for example, [37] (p. 2558)).

### 7.14. Operating Pressure

Specification of the operating pressure affects your calculation in different ways for different flow regimes. This section presents information about the operating pressure, its relevance for different cases, and how to set it correctly.

For additional information, see the following sections:
- 7.14.1. The Significance of Operating Pressure
- 7.14.2. Operating Pressure, Gauge Pressure, and Absolute Pressure
- 7.14.3. Setting the Operating Pressure

#### 7.14.1. The Significance of Operating Pressure

Operating pressure is significant for incompressible ideal gas flows because it directly determines the density: the incompressible ideal gas law computes density as 
\[ \rho = \frac{P_{op}}{R T} \]

You must therefore be sure to set the operating pressure appropriately.

In low-Mach-number compressible flow, the overall pressure drop is small compared to the absolute static pressure, and can be significantly affected by numerical roundoff. To understand why this is true, consider a compressible flow with \( M << 1 \). The pressure changes, \( \Delta p \), are related to the dynamic head, \( \frac{1}{2} \gamma p M^2 \), where \( p \) is the static pressure and \( \gamma \) is the ratio of specific heats. This gives the simple relationship \( \Delta p / p \sim M^2 \), so that \( \Delta p / p \rightarrow 0 \) as \( M \rightarrow 0 \). Therefore, unless adequate precaution is taken, low-Mach-number flow calculations are very susceptible to roundoff error.

Operating pressure is significant for low-Mach-number compressible flows because of its role in avoiding roundoff error problems. Ensure that you set the operating pressure appropriately. You may want to specify a floating operating pressure instead of a constant operating pressure for low-Mach-number, time-dependent compressible flows with average pressure in the domain varying in time. See *Floating Operating Pressure* (p. 529) for details.
Operating pressure is less significant for higher-Mach-number compressible flows. The pressure changes in such flows are much larger than those in low-Mach-number compressible flows, so there is no real problem with roundoff error and there is therefore no real need to use gauge pressure. In fact, it is common convention to use absolute pressures in such calculations. Since ANSYS Fluent always uses gauge pressure, you can simply set the operating pressure to zero, making gauge and absolute pressures equivalent.

If the density is assumed constant or if it is derived from a profile function of temperature, the operating pressure is not used in the density calculation.

Note that the default operating pressure is 101325 Pa.

### 7.14.2. Operating Pressure, Gauge Pressure, and Absolute Pressure

ANSYS Fluent avoids the problem of roundoff error (discussed in The Significance of Operating Pressure (p. 466)) by subtracting the operating pressure (generally a large pressure roughly equal to the average absolute pressure in the flow) from the absolute pressure, and using the result (termed the gauge pressure). The relationship between the operating pressure, gauge pressure, and absolute pressure is shown below. The absolute pressure is simply the sum of the operating pressure and the gauge pressure:

\[ p_{\text{abs}} = p_{\text{op}} + p_{\text{gauge}} \]  

(7.82)

All pressures that you specify and all pressures computed or reported by ANSYS Fluent are gauge pressures.

### 7.14.3. Setting the Operating Pressure

The criteria for choosing a suitable operating pressure are based on the Mach-number regime of the flow and the relationship that is used to determine density. For example, if you use the ideal gas law in an incompressible flow calculation (for example, for a natural convection problem), you should use a value representative of the mean flow pressure.

To place this discussion in perspective, Table 7.1: Recommended Settings for Operating Pressure (p. 467) shows the recommended approach for setting operating pressures. The default operating pressure is 101325 Pa.

**Table 7.1: Recommended Settings for Operating Pressure**

You will set the Operating Pressure in the Operating Conditions Dialog Box (p. 2095).

Cell Zone Conditions → Operating Conditions...
7.15. Reference Pressure Location

For incompressible flows that do not involve any pressure boundaries, ANSYS Fluent adjusts the gauge pressure field after each iteration to keep it from floating. This is done using the pressure in the cell located at (or nearest to) the reference pressure location. The pressure value in this cell is subtracted from the entire gauge pressure field; as a result, the gauge pressure at the reference pressure location is always zero. If pressure boundaries are involved, the adjustment is not needed and the reference pressure location is ignored.

The reference pressure location is, by default, the cell center at or closest to (0,0,0). There may be cases in which you might want to move the reference pressure location, perhaps locating it at a point where the absolute static pressure is known (for example, if you are planning to compare your results with experimental data). To change the location, enter new \((X,Y,Z)\) coordinates for Reference Pressure Location in the Operating Conditions Dialog Box (p. 2095).

Cell Zone Conditions → Operating Conditions...

For additional information, see the following section:
7.15.1. Actual Reference Pressure Location

7.15.1. Actual Reference Pressure Location

For cases that do not have pressure-related boundary conditions (for example, pressure inlet, pressure outlet, pressure far-field, etc.), you need to specify the Reference Pressure Location at a point in the problem domain. Internally, ANSYS Fluent sets the location of the reference pressure at a slightly different nearby location. Therefore, the actual location used as the pressure reference is different than that of your input value. To report the actual reference pressure location that ANSYS Fluent uses, use the following text command:

```
define → operating-conditions → used-ref-pressure-location
```

**Important**

- This text command is available only when the case is initialized and has no pressure-related boundary zones.
- Reporting the actual reference pressure location is not available through the graphical user interface.

7.16. Real Gas Models

Some engineering problems involve fluids that do not behave as ideal gases. For example, at very high-pressure or very low-temperature conditions (for example, the flow of a refrigerant through a compressor) the flow cannot typically be modeled accurately using the ideal-gas assumption. Therefore, the real gas model allows you to solve accurately for the fluid flow and heat transfer problems where the working fluid behavior deviates from the ideal-gas assumption.

ANSYS Fluent provides three real gas options for solving these types of flows:

- Cubic Equation of State Models (p. 471)
• The NIST Real Gas Models (p. 487)

• The User-Defined Real Gas Model (p. 492)

All the models allow you to solve for either a single-species fluid flow or a multiple-species mixture fluid flow.

For additional information, see the following sections:

7.16.1. Introduction
7.16.2. Choosing a Real Gas Model
7.16.3. Cubic Equation of State Models
7.16.4. The NIST Real Gas Models
7.16.5. The User-Defined Real Gas Model

7.16.1. Introduction

The states at which a pure material can exist can be graphically represented in diagrams of pressure vs. temperature (PT diagrams) and pressure vs. molecular or specific volume (PV diagrams). Homogeneous fluids are normally divided into two classes, liquids and gases. However the distinction cannot always be sharply drawn, because the two phases become indistinguishable at what is called the critical point. A typical pressure-temperature (PT) diagram of a pure material is shown in Figure 7.33: Typical PT Diagram of a Pure Material (p. 469).

Figure 7.33: Typical PT Diagram of a Pure Material

This figure shows the single phase regions, as well as the conditions of P and T where two phases co-exist. Therefore the solid and the gas region are divided by the sublimation curve, the liquid and gas regions by the vaporization curve, and the solid and liquid regions by the fusion curve. The three curves meet at the triple point, where all three phases coexist in equilibrium. Although the fusion curve continues upward indefinitely, the vaporization curve terminates at the critical point. The coordinates of this point are called the critical pressure $P_c$ and critical temperature $T_c$. These represent the highest temperature and pressure at which a pure material can exist in vapor-liquid equilibrium. At temperatures and pressures above the critical point, the physical property differences that differentiate the liquid phase from the gas phase become less defined. This reflects the fact that, at extremely high temperatures and pressures, the liquid and gaseous phases become indistinguishable. This new phase, which has
some properties that are similar to a liquid and some properties that are similar to a gas, is called a supercritical fluid.

**Figure 7.34: Typical PV Diagram of a Pure Material**

The dome shaped curve ACD is called the saturation dome and separates the single phase regions in the diagram; curve AC represents the saturated liquid and curve CD the saturated vapor. The area under the saturation dome ACD is the two-phase region and represents all possible mixtures of vapor and liquid in equilibrium. Curve ECB is the critical isotherm and exhibits a horizontal inflection at point C at the top of the dome. This is the critical point. The specific volume corresponding to the critical point, is called the critical specific volume $v_c$. The conditions to the right of the critical isotherm ECB correspond to supercritical fluid. The dashed lines CF and CG in Figure 7.34: Typical PV Diagram of a Pure Material (p. 470) represent the liquid and the vapor spinodal curves with the regions ACF and DCG between the saturation and spinodal lines representing the superheated liquid and supercooled vapor states, respectively. These states are called "metastable" because they exist temporarily in small local regions until phase change occurs. As an example, liquid metastable states may be formed in situations of fast depressurization, depending on the rate of depressurization and the disturbances that tend to make the liquid flash into vapor.

**7.16.2. Choosing a Real Gas Model**

The equation of state is the mathematical expression that relates pressure, molar or specific volume, and temperature for any pure homogeneous fluid in equilibrium states.

The simplest equation of state is the ideal gas law, which is approximately valid for the low pressure gas region of the PT and PV diagrams. Ideal gas behavior can be expected when
\[ \frac{P}{P_c} \ll 1 \]

or

\[ T / T_c > 2 \text{ and } \frac{P}{P_c} < 1 \]

If your flow conditions correspond to either of those cases, you may use the ideal gas law in your simulation.

Another idealization, that of the incompressible fluid, can be employed for the low pressure region of the liquid phase. A constant density option is the appropriate selection in that case.

However, both of these approaches are not good approximations for flow conditions close to and beyond the critical point, where the fluid behavior cannot be described by the ideal gas, or the incompressible liquid assumptions. We refer to a fluid under those conditions as a real fluid, or a real gas and more complex relations are used for the determination of its physical and thermodynamic properties.

ANSYS Fluent provides the following options for solving real fluid problems:

- The cubic equation of state models can be used to solve problems in the gas, liquid, and supercritical fluid regimes. The models are not available for the two-phase region under the phase dome. For further details see Cubic Equation of State Models (p. 471).

- The NIST real gas model can be used to solve problems in the liquid, or gas and supercritical fluid regimes. The model does not allow modeling of the two-phase region. For further details see The NIST Real Gas Models (p. 487).

- The user-defined real gas model allows you to solve problems in all regimes, as long as appropriate relationships are provided through the user-defined real gas functions. For further details see The User-Defined Real Gas Model (p. 492).

The concepts presented in this section for pure materials are also extended to multicomponent mixtures with the introduction of appropriate composition-dependent parameters in the real gas equations of state and the material property models. All the real-gas modeling options above allow for either single-species or multicomponent flow modeling. In addition, you may solve reacting flow problems with the cubic equations of state models and the user-defined real gas functions.

### 7.16.3. Cubic Equation of State Models

#### 7.16.3.1. Overview and Limitations

An equation of state is a thermodynamic equation, which provides a mathematical relationship between two or more state functions associated with the matter, such as its temperature, pressure, volume, or internal energy. One of the simplest equations of state for this purpose is the ideal gas law, which is roughly accurate for gases at low pressures and high temperatures. However, this equation becomes increasingly inaccurate at higher pressures and lower temperatures, and fails to predict condensation from a gas to a liquid.

Introduced in 1949, the Redlich-Kwong equation of state \[ [75] (p. 2561) \] was a considerable improvement over other equations of that time. It is an analytic cubic equation of state and is still of interest primarily due to its relatively simple form. The original form is

\[
P = \frac{RT}{V - b} - \frac{a_0}{V(V + b)T_r^{0.5}}
\]  

(7.83)
where

\[
\begin{align*}
P & = \text{absolute pressure (Pa)} \\
R & = \text{universal gas constant} \\
V & = \text{specific molar volume (m}^3/\text{kmol}) \\
T & = \text{temperature (K)} \\
T_r &= \text{reduced temperature } \frac{T}{T_c}, \text{ where } T_c \text{ is the critical temperature} \\
\alpha_0 \text{ and } b & \text{ are constants related directly to the fluid critical pressure and temperature}
\end{align*}
\]

Many investigators have attempted to improve the accuracy of the Redlich-Kwong equation. ANSYS Fluent has adopted the original form of the Redlich-Kwong equation, as well as the following modified forms:

- The Soave-Redlich-Kwong [97] (p. 2562) equation is a three-parameter equation of state, which can be applied for vapor, supercritical, and liquid property predictions. It has found wide acceptance mainly in the oil and gas industry and requires knowledge of the critical temperature, critical pressure, and acentric factor.

  It was developed by replacing the Redlich-Kwong attractive coefficient defined as \( \alpha = \alpha_0 / T_r^{0.5} \) with a two-parameter form \( \alpha (T_r, \omega) \), where \( \omega \) is the acentric factor.

- The Peng-Robinson equation [70] (p. 2560) is a three-parameter equation of state, also requiring the critical temperature, critical pressure and acentric factor parameters. It is thought to perform as well as the Soave-Redlich-Kwong equation, with an advantage in the prediction of the liquid densities.

- The Aungier-Redlich-Kwong [8] (p. 2557) equation provides improved predictions for vapor and supercritical fluids near the critical point, as well as for materials with a negative value of the acentric factor. The Aungier modified form is a four parameter equation and requires the critical specific volume in addition to the critical temperature, critical pressure and acentric factor.

The following limitations exist in ANSYS Fluent for all cubic equation of state models:

- Pressure-inlets, mass flow-inlets, and pressure-outlets are the only inflow and outflow boundaries available for use with the real gas models.

- Non-reflecting boundary conditions should not be used with the real gas models.

- The cubic equation of state real gas models are compatible with the Eulerian multiphase models.

---

**Note**

Note the following restrictions:

- Only one phase can be a real gas.

---

- The cubic equation of state models are compatible with the Lagrangian Dispersed Phase Models. If you are modeling droplet or multicomponent particles, note that the current formulation does not take into account the near-critical point phenomena, which means that accurate results can be obtained for droplet temperatures below \( T_{\text{lim}} = 0.9 T_c \). See Using the Cubic Equation of State Models with the Lagrangian Dispersed Phase Models (p. 485) for more details.
The real gas models are not available with the premixed, inert, and composition PDF transport combustion models.

The cubic equation of state real gas models can be used with the following species models:

- Species transport. Chemical reactions can be modeled with the finite rate and eddy dissipation models. Note that the Dimension Reduction model is not available with the real gas models.

- Non-premixed model and partially-premixed model. Note that the Compressibility Effects option must be enabled in the Species Model dialog box in order for the real-gas models to be available. In addition the following restrictions apply when the non-premixed model is used together with a cubic equation of state real-gas model:
  
  → The empirical stream options cannot be used, as for the empirical species the critical properties cannot be defined.
  
  → Condensed species such as h2o<l> and c<s> are not supported and should be excluded from the PDF table, so ensure that you add all condensed species for your system in the excluded species list prior to the PDF table generation. The laminar flame speeds for the partially-premixed model are assumed to be the same as for ideal-gases.

- When the cubic equation of state models are applied for subcritical conditions near or under the phase dome, the two-phase flow is not modeled and either vapor or liquid state must be selected. Subcritical and supercritical states can co-exist in the same simulation.

### 7.16.3.2. Equation of State

The general form of pressure P for the cubic equation of state models is written as [8] (p. 2557):

\[
P = \frac{RT}{V - b + \frac{\alpha}{V - \delta V + \varepsilon}}
\]

(7.84)

where

- \( P \) = absolute pressure (Pa)
- \( V \) = specific molar volume (m\(^3\)/kmol)
- \( T \) = temperature (K)
- \( R \) = universal gas constant

The coefficients \( \alpha, b, c, \delta, \) and \( \varepsilon \) are given for each equation of state as functions of the critical temperature \( T_c \), critical pressure \( P_c \), acentric factor \( \omega \) and critical specific volume \( V_c \). Note that the attractive coefficient \( \alpha \) also has a temperature dependence, which varies for each equation of state model, and is commonly written as \( \alpha = \alpha(T) \).

**Redlich-Kwong Equation** [79] (p. 2561):

\[
\alpha (T) = \frac{\alpha_0}{(T / T_c)^{0.5}}
\]

(7.85)

\[
\alpha_0 = 0.42747R^2T_c^2 / P_c
\]

(7.86)
The parameter \( \delta \) is set equal to \( b \), while \( c \) and \( \varepsilon \) are set to 0. The Redlich-Kwong equation is the simplest of the cubic equations of state in ANSYS Fluent and requires two parameters only, the critical temperature \( T_c \) and the critical pressure \( P_c \).

**Soave-Redlich-Kwong Equation** [97] (p. 2562):

\[
\alpha (T) = a_0 \left[ 1 + n \left( 1 - \left( \frac{T}{T_c} \right)^{0.5} \right) \right]^2
\]

\[ n = 0.48 + 1.574\omega - 0.176\omega^2 \] (7.89)

\( a_0 \) and \( b \) are given by Equation 7.86 (p. 473) and Equation 7.87 (p. 474) respectively. As in the original Redlich-Kwong equation the parameter \( \delta \) is set equal to \( b \), while \( c \) and \( \varepsilon \) are set to 0. The Soave-Redlich-Kwong requires three parameters, the critical temperature \( T_c \), the critical pressure \( P_c \), and the acentric factor \( \omega \).

**Peng-Robinson Equation** [70] (p. 2560):

\[
a_0 = \frac{0.457247R^2T_c^2}{P_c}
\]

\[
b = \frac{0.07780RT_c}{P_c}
\] (7.91)

The function \( \alpha (T) \) is given by Equation 7.88 (p. 474), with \( n \) provided in Equation 7.92 (p. 474) as follows:

\[ n = 0.37464 + 1.54226\omega - 0.26992\omega^2 \] (7.92)

In the Peng-Robinson equation \( \delta \) is set equal to \( 2b \), \( \varepsilon \) is equal to \( -b^2 \), and \( c \) is set to 0.

Similar to the Soave-Redlich-Kwong equation, the Peng-Robinson equation is a three-parameter equation and requires the critical temperature \( T_c \), the critical pressure \( P_c \), and the acentric factor \( \omega \).

**Aungier-Redlich-Kwong Equation** [8] (p. 2557):

\[
a(\theta) = a_0 \left( \frac{T}{T_c} \right)^{-n}
\]

\[ n = 0.4986 + 1.1735\omega + 0.4754\omega^2 \] (7.94)

\( a_0 \) and \( b \) are given by Equation 7.86 (p. 473) and Equation 7.87 (p. 474), respectively. As in the original Redlich-Kwong equation, the parameter \( \delta \) is set equal to \( b \) and \( \varepsilon \) is set to 0. Parameter \( c \) is given by:

\[
c = \frac{RT_c}{P_c + \frac{a_0}{V_c(V_c+b)}} + b - V_c
\] (7.95)

The Aungier-Redlich-Kwong equation requires four parameters, namely the critical temperature \( T_c \), the critical pressure \( P_c \), the critical specific volume \( V_c \), and the acentric factor \( \omega \).
7.16.3.3. Enthalpy, Entropy, and Specific Heat Calculations

Enthalpy, entropy, and specific heat are computed in terms of the relevant ideal gas properties and the departure functions. The departure function $F_{dep}$ of any conceptual property $F$ is defined as \[ F_{dep} = F_{ideal}(T, P) - F(T, P) \] (7.96)

where $F_{ideal}$ is the value of the property as computed from the ideal gas relations. The departure function $F_{dep}$ can be derived from basic thermodynamic relations and the equation of state.

Following the above definition, the enthalpy $H$ for the equations of state models is given by the following equations [8] (p. 2557):

\[
H = H_{ideal} - \frac{H_{dep}}{MW} \tag{7.97}
\]

\[
H_{dep} = -PV + RT - \frac{T}{\frac{\partial a}{\partial T} - \frac{a}{\Delta}} \ln \left( \frac{2V + \delta + \Delta}{2V + \delta - \Delta} \right) \tag{7.98}
\]

\[
\Delta = (\delta^2 - 4\varepsilon)^{0.5} \tag{7.99}
\]

where,

$H_{ideal}$ = ideal gas enthalpy at temperature $T$ (J/kg)

$H_{dep}$ = departure enthalpy (J/kmol)

$MW$ = mean molecular weight (Kg/kmol)

$P$ = pressure (Pa)

$V$ = specific molar volume (m$^3$/kmol)

$R$ = universal gas constant

$\alpha, \delta, \varepsilon$ are computed using Equation 7.85 (p. 473)– Equation 7.95 (p. 474) depending on the equation of state model.

See Equation 7.84 (p. 473) for a description of other coefficients.

Similarly, the departure internal energy $U_{dep}$ can be shown to be

\[
U_{dep} = -\frac{T}{\frac{\partial a}{\partial T} - \frac{a}{\Delta}} \ln \left( \frac{2V + \delta + \Delta}{2V + \delta - \Delta} \right) \tag{7.100}
\]

where

$U_{dep}$ = departure internal energy (J/kmol)

$T$ = temperature (K)

$V$ = specific molar volume (m$^3$/kmol)

$\Delta$ is given by Equation 7.99 (p. 475)

$\alpha, \delta, \varepsilon$ are computed using Equation 7.85 (p. 473) – Equation 7.95 (p. 474) depending on the equation of state model.
The specific heat $c_p$ can be computed from the ideal specific heat $c_{p,ideal}$ and the departure specific heat at constant volume $c_{v,dep}$ as follows:

$$
c_p = c_{p,ideal} - \frac{c_{p,dep}}{MW} \quad (7.101)
$$

$$
c_{p,dep} = c_{v,dep} - R - T \left( \frac{\partial V}{\partial T} \right) \frac{2}{\partial V / \partial P} \quad (7.102)
$$

where

$MW = \text{mean molecular weight (kg/kmol)}$  
$P = \text{pressure (Pa)}$  
$T = \text{temperature (K)}$  
$V = \text{specific molar volume (m}^3/\text{kmol)}$  
$R = \text{universal gas constant}$

In Equation 7.102 (p. 476) $c_{v,dep}$ is computed by differentiating the equation of departure internal energy (Equation 7.100 (p. 475)) with respect to $T$, and the partial derivatives of the specific volume are computed by differentiating Equation 7.84 (p. 473) appropriately.

The entropy $S$ is computed by

$$
S = S_{ideal,0} - \frac{S_{dep}}{MW} \quad (7.103)
$$

$$
S_{dep} = -R \ln \left( \frac{V - b + c}{V_0} \right) - \frac{da}{dT} \ln \left[ \frac{2V + \delta + \Delta}{2V + \delta - \Delta} \right] \quad (7.104)
$$

where

$S_{ideal,0} = \text{ideal gas entropy at temperature } T \text{ and reference pressure (J/kg/K)}$  
$V_0 = \text{ideal gas specific molar volume at temperature } T \text{ and the reference pressure (m}^3/\text{kmol)}$  
$P = \text{pressure (Pa)}$  
$T = \text{temperature (K)}$  
$V = \text{specific molar volume (m}^3/\text{kmol)}$  
$MW = \text{mean molecular weight (kg/kmol)}$

$\Delta$ is given by Equation 7.99 (p. 475) and $\alpha, \delta, \text{ and } \epsilon$ are computed using Equation 7.85 (p. 473) – Equation 7.95 (p. 474), depending on the equation of state model. Note that the pressure term in Equation 7.103 (p. 476) cancels out as both $S_{ideal,0}$ and $V_0$ are evaluated at the reference pressure.

### 7.16.3.4. Critical Constants for Pure Components

Equations describing real-gas properties require the knowledge of the critical constants for pure components and mixtures. These comprise the critical temperature ($T_c$), critical pressure ($P_c$), critical specific volume ($V_c$), and theacentric factor ($\omega$).
Several critical constants for fluid materials in the ANSYS Fluent property database propdb.scm have been compiled from a variety of sources available in the open literature [75] (p. 2561), [66] (p. 2560), [67] (p. 2560), [93] (p. 2562), [94] (p. 2562), [98] (p. 2562), [7] (p. 2557).

For those fluid materials, for which the critical properties have not been found in the open literature, these have been estimated using the commercially available software CRANIIU by Molecular Knowledge Systems Inc. [4] (p. 2557): http://www.molknow.com/Cranium/cranium.htm

Critical property values for many hydrocarbon and nitrogenous radical species have been obtained from Tang and Brezinsky [104] (p. 2562). Where the critical properties for the radicals were not available in the literature, these were estimated using a modification of the Joback method [75] (p. 2561). This assumes that the radical site constitutes a distinct group with zero group contribution and utilizes the group contribution values for stable species.

The critical properties of coal volatiles have been estimated assuming that the volatiles can be approximated by a mixture of CO, CO₂, H₂, CH₄, and C₂H₆ in such a way, that the atom composition and the net calorific value of the volatiles is similar to that of the assumed mixture. The critical properties of the lignite and biomass volatiles have been assumed equal to those of formaldehyde. The critical properties of diesel and jet-a fuels have been set equal to those of decane. The critical properties of kerosene have been set equal to those of dodecane.

### 7.16.3.5. Calculations for Mixtures

For the computation of properties in real-gas mixtures, ANSYS Fluent follows the so-called pseudocritical method. According to this method, the behavior and properties of a real gas mixture will be the same as that of a pure component, to which appropriate critical constants are assigned. These mixture critical constants are functions of the mixture composition and pure component critical properties, and are sometimes called pseudocritical constants, because their values are generally expected to be different from the true mixture critical constants that may be determined experimentally. However for computational purposes they are the appropriate critical constant values for the mixture. According to the pseudocritical method, ANSYS Fluent applies Equation 7.84 (p. 473)– Equation 7.104 (p. 476) also for mixtures, where the critical temperature $T_c$, critical pressure $P_c$, critical specific volume $V_c$, andacentric factor $\omega$, are replaced by the corresponding mixture critical constants, critical temperature $T_{cm}$, critical pressure $P_{cm}$, critical specific volume $V_{cm}$, andacentric factor $\omega_m$.

The following options are available in ANSYS Fluent for the calculation of the mixture pseudocritical constants:

- The simplest rule for computing the pseudocritical constants $C_{cm}$ for a real gas mixture is the mole fraction average [75] (p. 2561). This method is recommended for mixtures where the pure component critical properties for all components are not very different:

$$C_{cm} = \sum_{i=1}^{k} x_i C_{ci}$$  \hspace{1cm} (7.105)

where

- $C_{cm}$ = mixture pseudocritical constant (temperature, pressure, specific volume oracentric factor)
- $C_{ci}$ = critical constant of component i (temperature, pressure, specific volume oracentric factor)
- $x_i$ = mole fraction of component i

$k$ = number of components in mixture

- An alternative approach is based on the one-fluid van der Waals mixing rules as expressed in [79] (p. 2561). According to this approach, in order to apply the equation of state models to mixtures, the coefficients $a$ and $b$ in Equation 7.84 (p. 473) are replaced by composition-dependent expressions as follows:

\[
(a_m)^{0.5} = \sum_i x_i (\alpha_i)^{0.5} \tag{7.106}
\]

\[
b_m = \sum_i x_i b_i \tag{7.107}
\]

where

\[x_i = \text{mole fraction of species i}\]

With the appropriate expressions from Equation 7.85 (p. 473)– Equation 7.95 (p. 474) for each equation of state, and assuming a mixture acentric factor $\omega_m$ for the evaluation of parameter $n$ in Equation 7.89 (p. 474), Equation 7.92 (p. 474), and Equation 7.94 (p. 474), the mixing rules Equation 7.106 (p. 478) and Equation 7.107 (p. 478) can be rearranged to yield direct expressions of the mixture critical properties as functions of the mole fractions and the component critical properties [8] (p. 2557).

The resulting expressions for the mixture critical specific temperature $T_{cm}$ are as follows:

- Soave-Redlich-Kwong and Peng-Robinson models

\[
T_{cm} = \frac{\left( \sum_i x_i \left( \frac{T_i^{ci}}{P_i^{ci}^{0.5}} \right) \right)^2}{\sum_i x_i T_i^{ci}} \tag{7.108}
\]

- Redlich-Kwong model and Aungier-Redlich-Kwong model:

\[
T_{cm}^{1+n} = \frac{\left( \sum_i x_i \sqrt{\frac{T_i^{(2+n)}}{P_i^{ci}}} \right)^2}{\sum_i x_i T_i^{ci}} \tag{7.109}
\]

where for the Aungier-Redlich-Kwong model $n$ is obtained from Equation 7.94 (p. 474) as function of the mixture acentric factor $\omega_m$. For the Redlich-Kwong model $n = 0.5$.

The mixture critical specific pressure $P_{cm}$ is computed as:

\[
P_{cm} = \frac{T_{cm}}{\sum_i \left( \frac{x_i T_i^{ci}}{P_i^{ci}} \right)} \tag{7.110}
\]

The mixture critical specific volume $V_{cm}$ is computed as:
\[ V_{cm} = \sum_{i} x_i P_{ci} V_{ci} \left( \frac{T_{cm}}{P_{cm}} \right) \] (7.111)

The notation for Equation 7.108 (p. 478) to Equation 7.111 (p. 479) is

\[ T_{cm} = \text{mixture pseudocritical temperature (K)} \]
\[ P_{cm} = \text{mixture pseudocritical pressure (Pa)} \]
\[ V_{cm} = \text{mixture pseudocritical molar volume (m}^3/\text{kmol)} \]
\[ T_{ci} = \text{critical temperature for component i (K)} \]
\[ P_{ci} = \text{critical pressure for component i (Pa)} \]
\[ V_{ci} = \text{critical molar volume for component i (m}^3/\text{kmol)} \]
\[ x_i = \text{mole fraction for component i} \]

### 7.16.3.5.1. Using the Cubic Equation of State Real Gas Models

For single or multicomponent flows, you will activate the cubic equation of state real gas models by selecting **real-gas-soave-redlich-kwong**, **real-gas-peng-robinson**, **real-gas-aungier-redlich-kwong**, or **real-gas-redlich-kwong** from the Density drop-down list in the Create/Edit Materials dialog box.

Materials → Create/Edit...

The required inputs for the cubic equation of state real gas models for single component flow and mixtures are described below.

**Single Component Flow**
When any of the cubic equation of state models is enabled, enter the following material properties in the dialog box:

- ideal specific heat
- molecular weight
- standard state entropy
- reference temperature
- critical temperature
- critical pressure
- critical specific volume
- acentric factor

**Important**

Your inputs for the specific heat in the **Materials** dialog box will now be used to compute the ideal property functions $H_{ideal}$, $c_p, ideal$, and $S_{ideal,0}$ in Equation 7.97 (p. 475), Equa-
tion 7.101 (p. 476), and Equation 7.103 (p. 476), respectively. In ANSYS Fluent the departure properties will be computed and added to the ideal part, to yield the real gas specific heat, enthalpy, and entropy.

Mixtures

Figure 7.36: The Cubic Equation of State Model for a Real-Gas Mixture

When one of the cubic equation of state models is selected from the Density drop-down list, specify the following material properties for the mixture material in the dialog box:

- ideal specific heat
- critical temperature
- critical pressure
- critical specific volume
- acentric factor

You also need to enter the following material properties for each of the mixture components in the dialog box:

- molecular weight
- standard state entropy
- reference temperature
When you are modeling a real-gas mixture, the following methods are available for the mixture critical constants:

- **constant**: defines a constant critical temperature, critical pressure, critical specific volume, or acentric factor for the mixture material.

- **mole-weighted-mixing-law**: applies Equation 7.105 (p. 477) for critical temperature, critical pressure, critical specific volume, or acentric factor for the mixture material.

- **one-fluid-van-der-waals-mixing-law** applies Equation 7.108 (p. 478) and Equation 7.109 (p. 478) for the mixture critical temperature (depending on the real-gas model), Equation 7.110 (p. 478) for the mixture critical pressure, and Equation 7.111 (p. 479) for the mixture molar volume.

**Important**

- Ensure to click the **Change/Create** button so that all the above mentioned properties are uploaded and are visible in the interface.

- If you have selected **mixing-law** for the mixture ideal specific heat you will also need to enter the ideal specific heat values for the individual mixture components. If you have not selected **constant** as the option for any of the critical properties, you must enter the corresponding pure component critical properties for the mixture components.

If the operating conditions in your model are in the subcritical regime, select **Vapor** or **Liquid** as the **Real Gas Phase** in the **Operating Conditions** dialog box (Figure 7.37: The Operating Conditions for a Real Gas Phase (p. 482)). Alternatively, you can use the **define/operating-conditions/set-phase** text command. Note that the default is **Vapor** and therefore **Vapor** is assumed if no changes are made to the **Real Gas Phase** settings. If the operating conditions in your model are entirely in the supercritical regime, this setting will have no effect.

**Figure 7.37: The Operating Conditions for a Real Gas Phase**

![Operating Conditions dialog box](image-url)
In addition, you may specify the phase for a specific fluid zone by typing the following text command at the ANSYS Fluent console prompt:

```
> define boundary-conditions modify-zones change-zone-phase
Select a name/id from fluid zones list [{liquid-zone fluid-1}] liquid-zone
```

Set zone real-gas phase:
-1: use global setting
0: liquid
1: vapor
[-1] 0

7.16.3.5.2. Solution Strategies and Considerations for Cubic Equations of State Real Gas Models

The flow modeling of real-gas flow is more complex and challenging than simple ideal-gas flow. Therefore, the solution might converge at a slower rate with real-gas flow than when running ideal-gas flow. It is recommended that you first attempt to converge your solution using first-order discretization then switch to second-order discretizations and re-iterate to convergence.

Special considerations apply if the operating regime in your model is fully or partly subcritical, where the physical state may be vapor, liquid, or a vapor/liquid mixture. In the cubic EOS real-gas model, the phase state is determined by the selection of the cubic root to calculate the molar-volume. This is illustrated in Figure 7.38: The PV Diagram for the Cubic Equation of State Real Gas Model (p. 484), which shows a pressure versus molar volume (PV) diagram, with a subcritical isotherm ABFED at temperature $T$ calculated from a cubic EOS. Curve C1CC2 represents the critical isotherm and curve ACD the saturation dome. Points A, F, and D represent the three roots of the EOS at the saturation pressure $P_s$, where A corresponds to the molar volume of saturated liquid, D to the molar volume of saturated vapor and point F does not have a physical significance. Points A1 and D1 correspond to the liquid and vapor molar volumes at pressure $P_1$, which is lower than the saturation pressure. The liquid and vapor molar volumes at pressure $P_2$, which is higher than the saturation pressure, are marked as A2 and D2 respectively. Points B and E, where the partial derivatives of pressure with respect to volume $\left(\frac{\partial P}{\partial V}\right)_T$ are 0, are called spinodal points. The loci of these points for all subcritical temperatures, the spinodal curve, is shown with the dashed curve BCE and sets the boundary beyond which the equation of state is no longer valid, because the local derivative of pressure with respect to volume becomes positive. State points inside the dome, up to the spinodal curve, are called “metastable” because normally they only exist temporarily in small local regions until phase change occurs.
It is important to realize that the current implementation of the cubic equations of state real gas model does not determine the saturation conditions and does not model the two-phase flow where liquid and vapor coexist. In the subcritical regime and for conditions where the cubic EOS has three roots, the phase state selection is controlled by your input of Vapor or Liquid for Real Gas Phase in the Operating Conditions dialog box (Figure 7.37: The Operating Conditions for a Real Gas Phase (p. 482)). The default setting is Vapor, which corresponds to the state points to the right of the vapor spinodal. With reference to Figure 7.38: The PV Diagram for the Cubic Equation of State Real Gas Model (p. 484), for the operating point at temperature T and pressure P1, if the Real Gas Phase is set to Vapor, the molar volume at point D1, which corresponds to superheated vapor, will be selected in the calculation. On the other hand, if you have selected Liquid, the molar volume of point A1 will be taken, and the corresponding state will be metastable superheated liquid. Similarly for pressure P2, which is higher than the saturation pressure Ps, if you select Liquid for Real Gas Phase, the liquid molar volume at A2 will be computed, and if you select Vapor the molar volume will correspond to the subcooled vapor state point D2.

In case the calculations fall inside the saturation dome, the solver will not limit the solution, but if conditions are predicted that extend beyond the vapor spinodal curve a warning will be issued:

temperature is below the spinodal point in 12 cells on zone 3.DE27233

Cubic equations of state real gas models are not available for two-phase flows but can be applied to conditions of supercritical pressure $P > P_c$ and subcritical temperature $T < T_c$, where the fluid is in the liquid state, and the supercritical liquid co-exists with gas and supercritical fluid in the same simulation.
In those cases, phase change may take place, without any of the flow conditions falling inside the saturation dome.

For multicomponent simulations, when **Diffusion Energy Source** is enabled in the **Species Model** dialog box, the species energy diffusion is by default suppressed in the supercritical liquid regime and across the gas-liquid boundary. The diffusion energy source can be included in the liquid regime using the `define/models/species/liquid-energy-diffusion?` text command.

### 7.16.3.5.3. Using the Cubic Equation of State Models with the Lagrangian Dispersed Phase Models

If your simulation contains a liquid stream, the appropriate modeling approach in the various operating condition regimes is as follows:

1. For \( T > T_c \), a liquid phase does not exist.

2. In the region \( P > P_c \), you should define the flow streams directly in the boundary conditions by setting the appropriate pressure and temperature and the properties will be computed directly by the cubic EOS.

3. For \( P < P_c \), a stream can exist in liquid phase when its temperature \( T < T_c \). If you would like to model phase change in this regime, the following recommendations apply:
   - The DPM droplet and multicomponent models are adequate and recommended for the conditions away from the critical point. This regime can be defined as \( T < 0.9T_c \), where the liquid physical properties can be assumed independent of pressure.
   - The region \( T_c > T > 0.9T_c \) is characterized by near-critical-point phenomena, such as strong liquid density and specific heat dependence on both temperature and pressure. The DPM model can also be used in this regime, but you should be cautious, as it will not take into consideration the near-critical-point behavior. In addition, the applicability of the evaporation and boiling rate equations is questionable in this regime.

The droplet saturation vapor pressure corresponding to \( T_{lim} = 0.9T_c \) gives an indication of the maximum operating pressure for applicability of the DPM models for each droplet material. These pressure limits are listed in Table 7.2: Pressure Limits for Droplet Materials in ANSYS Fluent’s Database `prodb.scm` (p. 485) for many of the droplet materials in ANSYS Fluent’s `propdb.scm` materials database.

### Table 7.2: Pressure Limits for Droplet Materials in ANSYS Fluent’s Database `prodb.scm`

</tbody>
</table>
For high pressure simulations the boiling point will be different from the normal boiling point, and for varying pressure applications the boiling point will vary with the droplet location in the domain. When a cubic equation of state real gas model is enabled in a simulation that includes evaporating droplet particles, the boiling point is calculated from the vapor pressure data directly, as the temperature where the saturation vapor pressure equals the domain pressure. In addition, the latent heat of the evaporating or boiling droplet will vary with the droplet temperature.

The latent heat at temperature $T_p$ is given by

$$H_{\text{lat}_T} = -\int_{T_p}^{T_{bp}} c_{p,g}dT + H_{\text{lat}_{bp}} + \int_{T_p}^{T_{bp}} c_{p,p}dT$$  \hspace{1cm} (7.112)

where $T_{bp}$ is the normal boiling point and $H_{\text{lat}_{bp}}$ is the latent heat at the normal boiling point.

In the Create/Edit Materials dialog box you must enter the Normal Boiling Point (NBP) and the Latent Heat at NBP for the droplet-particle Material Type. These inputs will be used for calculating the Latent Heat at the reference temperature (see Equation 16.330) and the latent heat in the droplet energy balance during vaporization and boiling according to Equation 7.112 (p. 486).

**Important**

The constant property option is disabled for the Saturation Vapor Pressure property when a real gas model is used in the simulation. Also, ensure to enter the appropriate droplet saturation vapor pressure data to cover the complete pressure/temperature range in your model.

Finally when a cubic equation of state real-gas model is enabled in a simulation with droplet models, the condition for switching from the vaporization to the boiling law will be

$$P_{\text{sat}} > P$$  \hspace{1cm} (7.113)

where $P_{\text{sat}}$ is the saturation vapor pressure and $P$ is the domain pressure. If $P_{\text{sat}} < P$ while in the boiling law, the model will switch back to the vaporization law.

### 7.16.3.5.4. Postprocessing the Cubic Equations of State Real Gas Model

All postprocessing functions properly report and display the current thermodynamic and transport properties of the selected real gas model. The thermodynamic and transport properties controlled by the cubic equations of state real gas model include the following:

- density
- enthalpy

<table>

• sound speed
• specific heat
• any quantities that are derived from the properties listed above (for example, total quantities, ratio of specific heats)

In addition to the properties listed above, you can also report

• compressibility factor
• reduced temperature
• reduced pressure
• spinodal temperature
• subcritical condition

If you are modeling a real-gas mixture you can report the composition-dependent mixture critical properties

• critical temperature
• critical pressure
• critical specific volume
• acentric factor

### 7.16.4. The NIST Real Gas Models

The NIST real gas models use the National Institute of Standards and Technology (NIST) Thermodynamic and Transport Properties of Refrigerants and Refrigerant Mixtures Database Version 7.0 (REFPROP v7.0) to evaluate thermodynamic and transport properties of approximately 39 pure fluids or a mixture of these fluids.

The REFPROP v7.0 database is a shared library that is dynamically loaded into the solver when you activate one of the NIST real gas models in an ANSYS Fluent session. Once the NIST real gas model is activated, control of relevant property evaluations is relinquished to the REFPROP database. All postprocessing functions will properly report and display the current thermodynamic and transport properties of the real gas.

#### 7.16.4.1. Limitations of the NIST Real Gas Models

The following limitations exist for the NIST real gas model:

• When you are using the NIST real gas models, the NIST materials defined in your simulation will appear in the Create/Edit Materials Dialog Box (p. 2022) either with the name `real-gas-_name`, where `_name` is the NIST material selected for the single species model, or with the name `real-gas-mixture` for the multiple species model. The inputs for the properties calculated by the NIST functions are disabled. You can use the Create/Edit Materials Dialog Box (p. 2022) to define or modify:
Physical Properties

- Mass diffusivity property in the **real-gas-mixture** material if you are using the multiple-species NIST real gas model (note that the **kinetic-theory** option is not available)

- Radiation properties if you are modeling radiation

- Properties of materials other than the NIST **real-gas-mixture** or **real-gas-fluid** materials

  • The NIST real gas model assumes that the fluid you will be using in your ANSYS Fluent computation is superheated vapor, supercritical fluid, or liquid. Note that subcritical flow conditions, where vapor coexists with liquid in two-phase flow, are not supported. In addition, all fluid zones must contain the real gas; you cannot include a real gas and another fluid in the same problem.

  • Pressure-inlet, mass flow-inlet, and pressure-outlet are the only inflow and outflow boundaries available for use with the real gas models.

  • Non-reflecting boundary conditions should not be used with the real gas models.

  • The mixture flow does not permit chemical reactions with the NIST real gas model.

  • The real gas models cannot be used with any of the multiphase models. The model is compatible with the Lagrangian Dispersed Phase Models only for the massless and inert particle types.

  • You cannot modify material properties in the REFPROP database libraries, or add custom materials to the NIST real gas model.

  • The **Diffusion Energy Source** \( \nabla \cdot \left( \sum_{j} h_{j} \bar{J}_{j} \right) \) in the energy equation (see The Energy Equation in the Theory Guide) is not included with the nist-multispecies-real-gas-models and the pressure-based solver.

### 7.16.4.2. The REFPROP v7.0 Database

The NIST real gas model supports 83 pure fluids from the REFPROP database. These include 39 materials that were made available in the NIST web site later. The pure-fluid refrigerants and hydrocarbons that are supported by REFPROP v7.0 and used in the NIST real gas model are listed in Table 7.3: Hydrocarbons and Refrigerants Supported by REFPROP v7.0 (p. 489) (the corresponding property file name appears in parentheses, where it does not coincide with the fluid name).

<table>
<thead>
<tr>
<th>Important</th>
</tr>
</thead>
</table>

The database does not include transport property models for the following species: acetone, benzene, c4f10, c5f12, cos, cyclohexane, cyclopropane, deuterium, fluorine, neopentane, nf3, propyne, r21, sf6, so2. As a result the NIST real gas model with those species can only be used for modeling inviscid flow.

The REFPROP v7.0 database employs accurate pure-fluid equations of state that are available from NIST. These equations are based on three models:

- modified Benedict-Webb-Rubin (MBWR) equation of state

- Helmholtz-energy equation of state

- extended corresponding states (ECS)
For a fluid that consists of a multispecies-mixture the thermodynamic properties are computed by employing mixing-rules applied to the Helmholtz energy of the mixture components.

7.16.4.3. Using the NIST Real Gas Models

When you enable one of the NIST real gas models (single-species fluid or multiple-species mixture) and select a valid material, ANSYS Fluent's functionality remains the same as when you model fluid flow and heat transfer using an ideal gas, with the exception of the Create/Edit Materials Dialog Box (p. 2022) (see below).

7.16.4.3.1. Activating the NIST Real Gas Model

Activating one of the NIST real gas models is a two-step process. First you enable either the single-species NIST real gas model or the multi-species NIST real gas model, and then you select the fluid material from the REFPROP database.

1. Enabling the appropriate NIST real gas model:

   If you are solving for a single-species flow then you should enable the single-species NIST real gas model by typing the following text command at the ANSYS Fluent console prompt:

   ```
   > define/user-defined/real-gas-models/nist-real-gas-model
   use NIST real gas? [no] yes
   ```

   If you are solving for multi-species mixture then you should enable the multi-species NIST real gas model by typing the following text command at the ANSYS Fluent console prompt:

   ```
   > define/user-defined/real-gas-models/multi-species-nist-real-gas
   use multi-species NIST real gas? [no] yes
   ```
The list of available pure-fluid materials you can select from will be displayed:

1butene.fld acetone.fld ammonia.fld argon.fld benzene.fld
butene.fld c12.fld c2butene.fld c4f10.fld c5f12.fld
co.fld co2.fld cos.fld cyclohex.fld cyclopro.fld
d2.fld d2o.fld decane.fld dme.fld ethane.fld
ethanol.fld ethylene.fld fluorine.fld h2s.fld helium.fld
heptane.fld hexane.fld hydrogen.fld ibutene.fld ihexane.fld
ipentane.fld isobutan.fld krypton.fld methane.fld methanol.fld
n2o.fld neon.fld neopentn.fld nf3.fld nitrogen.fld
nonane.fld octane.fld oxygen.fld parahyd.fld pentane.fld
propane.fld propylen.fld propyne.fld r11.fld r113.fld
r114.fld r115.fld r116.fld r12.fld r123.fld
r124.fld r125.fld r13.fld r134a.fld r14.fld
r141b.fld r142b.fld r143a.fld r152a.fld r18.fld
r21.fld r22.fld r227ea.fld r23.fld r236ea.fld
r236fa.fld r245ca.fld r245fa.fld r32.fld r365mfc.fld
r41.fld rc318.fld so2.fld t2butene.fld
toluene.fld water.fld xenon.fld

2. Select material from the REFPROP database list:

If the single-species real gas model is selected, then you need to enter the name of one fluid material when prompted:

```
select real-gas data file "r125.fld"
```

**Important**

You must enter the complete name of the material (including the .fld suffix) contained within quotes (" ").

If the multiple-species real gas model is selected, then you need to enter the number of species in the mixture:

```
Number of species [] 3
```

followed by the name of each fluid selected from the list shown above:

```
select real-gas data file "nitrogen.fld"
select real-gas data file "co2.fld"
select real-gas data file "r22.fld"
```

Upon selection of a valid material (for example, r125.fld), ANSYS Fluent will load data for that material from a library of pure fluids supported by the REFPROP database, and report that it is opening the shared library (librealgas.so) where the compiled REFPROP database source code is located.

```
Opening "/usr/local/ansys_inc/v150/fluent/fluent15.0.0/realgas/lib/r125.fld"
```

```
Setting material "air" to a real-gas...
```

```
Matl name: "R125"
: "pentfluoroethane !full name"
: "354-33-6"
Mol Wt : 120.021
```

```
Critical properties:
Temperature : 339.173 (K)
```
Pressure : 3.6177e+06 (Pa)
Density  : 4.779 (mol/L) 573.582 (kg/m^3)

Equation Of State (EOS) used:
Helmholtz Free Energy (FEQ)
EOS:"FEQ Helmholtz equation of state for R-125 of Lemmon and Jacobsen (2002)."

EOS Range of applicability
Min Temperature: 172.52 (K)
Max Temperature: 500 (K)
Max Density : 1691.1 (kg/m^3)
Max Pressure  : 6e+07 (Pa)

Thermal conductivity Range of applicability
Min Temperature: 172.52 (K)
Max Temperature: 500 (K)
Max Density : 1691.1 (kg/m^3)
Max Pressure  : 6e+07 (Pa)

Viscosity Range of applicability
Min Temperature: 172.52 (K) Max Temperature: 500 (K)
Max Density : 1692.3 (kg/m^3)
Max Pressure  : 6e+07 (Pa)

3. If you would like to model flow in the liquid phase, then this must be specified in the set-phase command. Note that the default phase is vapor, so if you do not go through this step, vapor is assumed. Also, if the flow conditions do not permit liquid to exist, a vapor calculation will be performed instead.

> define/user-defined/real-gas-models/set-phase
Select vapor phase (else liquid)?[yes]

In addition, you may specify the phase for a specific fluid zone by typing the following text command at the ANSYS Fluent console prompt:

> define boundary-conditions modify-zones change-zone-phase
Select a name/id from fluid zones list [(liquid-zone fluid-1)] liquid-zone
Set zone real-gas phase:
-1:use global setting
 0:liquid
 1:vapor
[-1]  0

Important

For mixture flows, not all combinations of species mixtures are allowed. This could be due to lack of data for one or more binary pairs. In such situations an error message generated by NIST will be returned and displayed on the ANSYS Fluent console, and no real gas material is allowed to be created. In some combinations the mixing data will be estimated, a warning message will be displayed on the ANSYS Fluent console and the mixture material allowed to be created.

7.16.4.4. Solution Strategies and Considerations for NIST Real Gas Model Simulation

The flow modeling of NIST real-gas flow is much more complex and challenging than simple ideal-gas flow. Therefore, you should expect the solution to converge at much slower rate with real-gas flow than when running ideal-gas flow. Also due to the complexity of the equations used in property evaluations, converging a solution with the real-gas model is in general done at much lower Courant values when you are using the density-based solver, or at much lower under-relaxation values if you are using the pressure-based solver. It is recommended that you first attempt to converge your solution using first-order discretization, then switch to second-order discretizations and re-iterate to convergence.
The real-gas properties in NIST are defined within a limited/bounded range. It is important that the flow conditions you are prescribing fall within the range of the database. It is possible that you specify flow at a state that is physically valid but otherwise not defined in the database. In this situation the solution will diverge or immediately generate an error message on the ANSYS Fluent console as soon as the state crosses the limit of the database. In some instances, the actual converged state is just within the bounded defined database but only transitory outside the range. In this situation the divergence can be avoided by lowering the Courant value or under-relaxation factors so a less aggressive convergence rate is adapted.

Finally, if you attempt to initialize the flow from an inlet flow conditions and an error message is generated from one of the property routines, then this is an indicator that the flow conditions you have specified is not defined within the range of the database.

7.16.4.4.1. Writing Your Case File

When you save your completed real gas model to a case file, the linkage to the shared library containing real gas properties will be saved to the case file (along with property data for the material you selected in the NIST real gas model). Consequently, whenever you read your case file in a later session, ANSYS Fluent will load and report this information to the console during the read process.

7.16.4.4.2. Postprocessing

All postprocessing functions properly report and display the current thermodynamic and transport properties of the selected real gas model. The thermodynamic and transport properties controlled by the NIST real gas model include the following:

- density
- enthalpy
- entropy
- molecular weight
- molecular viscosity
- sound speed
- specific heat
- thermal conductivity In addition to the properties listed above, you can also report
- compressibility factor
- any quantities that are derived from the properties listed above (for example, total quantities, ratio of specific heats)

7.16.5. The User-Defined Real Gas Model

The user-defined real gas model (UDRGM) has been developed to allow you to write your own custom real gas model to fit your particular modeling needs. It also allows you to simulate a single-species flow, multiple-species mixture flow, multiphase flow, or volumetric reactions.

The following limitations exist for the UDRGM:
7.16.5.1. Limitations of the User-Defined Real Gas Model

- You cannot include more than one user-defined real gas material (fluid or mixture) in the same problem. However, you can use other materials together with real gas in your simulation.

- When you are using the UDRGM, the materials defined in your real gas UDF will appear in the Create/Edit Materials Dialog Box (p. 2022) with the name real-gas-fluid or real-gas-mixture and all physical and thermodynamic property inputs disabled. Use the Create/Edit Materials Dialog Box (p. 2022) to define or modify:
  - Mass diffusivity property in the real-gas-mixture material if you are modeling multicomponent flow.
  - Chemical reactions in the real-gas-mixture if you are modeling reacting flow.
  - Radiation properties for the real-gas-mixture or the real-gas-fluid materials if you are modeling radiation.
  - Properties of materials other than the user-defined real-gas-mixture or real-gas-fluid materials.

**Note**

If you are using the UDRGM together with other materials from ANSYS Fluent's property database in dispersed phase or multiphase calculations, take care to use the same reference temperature as in ANSYS Fluent in your real-gas UDF. The reference temperature in ANSYS Fluent is 298.15 K.

- Pressure-inlets, mass flow-inlets, and pressure-outlets are the only inflow and outflow boundaries available for use with the real gas models.

- Non-reflecting boundary conditions should not be used with the real gas models.

- The UDRGM can be used with the Eulerian multiphase models.

**Note**

Note the following restrictions:

- Only one phase can be a real gas.

- The UDRGM is compatible with the Lagrangian Dispersed Phase Models. Refer to Using the Cubic Equation of State Models with the Lagrangian Dispersed Phase Models (p. 485) for guidelines and restrictions of this approach.

- The real gas models cannot be used with the non-premixed, partially premixed, and composition PDF transport combustion models. Chemical reactions can however be modeled with the finite rate and eddy dissipation models. Note that the Dimension Reduction model is not available with the real gas models.

The UDRGM requires a library of functions written in the C programming language. Moreover, there are certain coding requirements that need to be followed when writing these functions. Sample real gas function libraries are provided to assist you in writing your own UDRGM. When UDRGM functions are compiled, they will be grouped in a shared library that later will be loaded and linked with the ANSYS Fluent executable. The procedure for using the UDRGM is defined as follows:
1. Define the real gas equation of state and all related thermodynamic and transport property equations.

2. Create a C source code file that conforms to the format defined in this section.

3. Start ANSYS Fluent and set up your case file in the usual way.

4. Compile your UDRGM C library and build a shared library file (you can use the available compiled UDF utilities in either the graphical user interface or the text command interface).

5. Load your newly created UDRGM library via the text command menu:

   If a single-species UDRGM to be used, then the text command menu is:
   
   > define/user-defined/real-gas-models/user-defined-real-gas-model
   
   use user defined real gas? [no] yes
   
   On the other hand, if you are simulating multiple-species UDRGM flow, then the text command menu to use is:
   
   > define/user-defined/real-gas-models/user-defined-multispecies-real-gas-model
   
   use user multispecies defined real gas? [no] yes
   
   Upon activating the UDRGM, the function library will now supply the fluid material properties for your case.

6. You can simulate volumetric reactions with your real gas model using the Species Model Dialog Box (p. 1943), or the text interface (define/models/species/volumetric-reactions?).

   You can access the Species Model by selecting Models from the navigation pane and double-clicking Species in the task page.

   In the Species Model Dialog Box (p. 1943)

   • Enable Species Transport under Model.
   
   • Enable Volumetric under Reactions.
   
   • Select the appropriate Turbulence-Chemistry Interaction option.
   
   • Set up the reaction by clicking the Edit... button for the real-gas-mixture Mixture Material.

   ________________ Important ________________

   Note that the fluid materials and their properties, appearing in the Create/Edit Materials Dialog Box (p. 2022), are the ones defined in your real gas UDF. You cannot modify the materials via this dialog box, however, you can set up the volumetric reaction. If you would like to modify the mixture materials and their properties, this should be done in the real gas UDF. The volumetric reactions for your real gas mixture are defined in the same way as for any ANSYS Fluent mixture. For details, refer to Defining Reactions (p. 896).
Alternatively, the chemical reactions can be set up using the `define/models/species` and `define/materials` text command.

**Important**

Note that the chemical reactions should be activated after your real gas UDF has been built and loaded. It is also recommended to test and validate your real gas UDF, running the cold flow calculation prior to attempting to solve the reacting flow. Also, make sure that the applicability range of the real gas functions in your UDF fully covers the temperature and pressure range of the reacting flow calculation.

7. Run your calculation.

When using the UDRGM the robustness of the solver and the speed of flow convergence will largely depend on the complexity of the material properties you have defined in your UDF. It is important to understand the operational range of the property functions you are coding so you can simulate the flow within that range.

7.16.5.2. Writing the UDRGM C Function Library

Creating a UDRGM C function library is reasonably straightforward; however, your code must make use of specific function names and macros, which will be described in detail below. The basic library requirements are as follows:

- The code must contain the `udf.h` file inclusion directive at the beginning of the source code. This allows the definitions for `DEFINE` macros and other ANSYS Fluent functions to be accessible during the compilation process.
- The code must include at least one in the UDF's `DEFINE` functions (that is `DEFINE_ON_DEMAND`) to be able to use the compiled UDFs utility (see the sample UDRGM codes provided below).
- Any values that are passed to the solver by the UDRGM or returned by the solver to the UDRGM are assumed to be in SI units.
- You must use the principal set of functions listed below in your UDRGM library. These functions are the mechanism by which your thermodynamic property data are transferred to the ANSYS Fluent solver. Note that `ANYNAME` can be any string of alphanumeric characters, and allows you to provide unique names to your library functions.

Function inputs from the ANSYS Fluent solver consist of one or more of the following variables:

\[
\begin{align*}
T &= \text{Temperature, K} \\
p &= \text{Pressure, Pa} \\
\rho &= \text{Density, kg/m}^3
\end{align*}
\]
\( Y_i[] = \text{Species mass fraction} \)

**Important**

\( Y_i[] \): ANSYS Fluent solver returns a value of 1.0 for \( Y_i[] \) in single-species flows. For multiple-species flows, \( Y_i[] \) is a vector array containing species mass fraction in an order defined by the user setup function.

The UDRGM function names and argument lists, followed by a short description of the function, are as follows:

```c
void ANYNAME_error(int err, char *f, char *msg)
prints error messages.
```

```c
void ANYNAME_Setup(Domain *domain, cxboolean vapor_phase, char *filename,int (*messagefunc)(char *format,...), void (*errorfunc)(char *format, ...))
performs model setup and initialization. Can be used to read data and parameters related to your UDRGM. When writing UDFs for multiple-species, use this function to specify the number of species and the name of the species as shown in the multiple-species example. The boolean variable, vapor_phase, passes to your UDF the setting of the text-interface command define/user-defined/real-gas-models/set-phase.
```

```c
double ANYNAME_density(cxboolean vapor_phase, double T, double P, double yi[])
returns the value of density as a function of phase, temperature, pressure and species mass-fraction if applicable. The boolean variable vapor_phase passes to your UDF the setting of the text-interface command define/user-defined/real-gas-models/set-phase, or, if applicable, the zone phase set by the text-interface command define/boundary-conditions/modify-zones/change-zone-phase.
```

**Important**

Since this function is called numerous times during each solver iteration, it is important to make this function as numerically efficient as possible.

```c
double ANYNAME_specific_heat(double T, double Rho, double P, double yi[])
returns the real gas specific heat at constant pressure as a function of temperature, density, absolute pressure, and species mass-fraction if applicable.
```

```c
double ANYNAME_enthalpy(double T, double Rho, double P, double yi[])
returns the enthalpy as a function of temperature, density, absolute pressure, and species mass-fraction if applicable.
```

```c
double ANYNAME_entropy(double T, double Rho, double P, double yi[])
returns the entropy as a function of temperature, density, absolute pressure, and species mass-fraction if applicable.
```

```c
double ANYNAME_mw(double yi[])
returns the fluid molecular weight.
```
double ANYNAME_speed_of_sound(double T, double Rho, double P, double yi[]) 
returns the value of speed of sound as a function of temperature, density, absolute pressure, and species mass-fraction if applicable.

double ANYNAME_viscosity(double T, double Rho, double P, double yi[]) 
returns the value of dynamic viscosity as a function of temperature, density, absolute pressure, and species mass-fraction if applicable.

double ANYNAME_thermal_conductivity(double T, double Rho, double P, double yi[]) 
returns the value of thermal conductivity as a function of temperature, density, absolute pressure, and species mass-fraction if applicable.

double ANYNAME_rho_t(double T, double Rho, double P, double yi[]) 
returns the value of \( \frac{dp}{dT} \) at constant pressure as a function of temperature, density, absolute pressure, and species mass-fraction if applicable.

double ANYNAME_rho_p(double T, double Rho, double P, double yi[]) 
returns the value of \( \frac{dp}{dp} \) at constant temperature as a function of temperature, density, absolute pressure, and species mass-fraction if applicable.

double ANYNAME_enthalpy_t(double T, double Rho, double P, double yi[]) 
returns the value of \( \frac{dh}{dT} \) at constant pressure as a function of temperature, density, absolute pressure, and species mass-fraction if applicable. Note that by definition \( \frac{dh}{dT} = c_p \), so this function should simply return the specific heat value.

double ANYNAME_enthalpy_p(double T, double Rho, double P, double yi[]) 
returns the value of \( \frac{dh}{dp} \) at constant temperature as a function of temperature, density, absolute pressure, and species mass-fraction if applicable.

double ANYNAME_enthalpy_prime(double T, double Rho, double P, double yi[], double hi[]) 
returns the value of the mixture enthalpy as a function of temperature, density, absolute pressure, and species mass fraction. In addition, your UDF must set the elements of the double array hi[] to the enthalpy of each species, in the same order as they are referenced in the mass fraction array yi[]. Note that the enthalpy in the function enthalpy_prime is defined as the sum of sensible enthalpy plus species formation enthalpy, and you should make sure that its computation is consistent with the sensible enthalpy function ANYNAME_enthalpy. The function ANYNAME_enthalpy_prime is required for the calculation of the heat of reactions, if chemical reactions are being simulated. If you are not solving reacting flows, the function ANYNAME_enthalpy_prime can simply be omitted.
At the end of the code you must define a structure of type `RGAS_Function` whose members are pointers to the principal functions listed above. The structure is of type `RGAS_Function` and its name is `RealGasFunctionList`.

**Important**

It is imperative that the sequence of function pointers shown below be followed. Otherwise, your real gas model will not load properly into the ANSYS Fluent code.

```c
UDF_EXPORT RGAS_Functions RealGasFunctionList =
{
    ANYNAME_Setup,                   /* Setup initialize */
    ANYNAME_density,                 /* density */
    ANYNAME_enthalpy,                /* sensible enthalpy */
    ANYNAME_entropy,                 /* entropy */
    ANYNAME_specific_heat,           /* specific heat */
    ANYNAME_mw,                      /* molecular weight */
    ANYNAME_speed_of_sound,          /* speed of sound */
    ANYNAME_viscosity,               /* viscosity */
    ANYNAME_thermal_conductivity,    /* thermal conductivity */
    ANYNAME_rho_t,                   /* drho/dT |const p */
    ANYNAME_rho_p,                   /* drho/dp |const T */
    ANYNAME_enthalpy_t,              /* dh/dT |const p */
    ANYNAME_enthalpy_p               /* dh/dp |const T */
    ANYNAME_enthalpy_prime           /* enthalpy */
};
```

If volumetric reactions are not being simulated, then the function `ANYNAME_enthalpy_prime` can be removed or ignored from the `RealGasFunctionList` structure described here.

The principal set of functions described are the only functions in the UDRGM that will be interacting directly with the ANSYS Fluent code. In many cases, your model may require further functions that will be called from the principal function set. For example, when multiple-species real gas model UDFs are written, the principal functions will return the mixture thermodynamic properties based on some specified mixing-law. Therefore, you may want to add further functions that will return the thermodynamic properties for the individual species. These auxiliary functions will be called from the principal set of functions. See **User-Defined Real Gas Models (UDRGM)** in the UDF Manual for examples that clearly illustrate this strategy.

### 7.16.5.3. Compiling Your UDRGM C Functions and Building a Shared Library File

This section presents the steps you must follow to compile your UDRGM C code and build a shared library file. This process requires the use of a C compiler. Most Linux operating systems provide a C compiler as a standard feature. If you are using a PC, you must ensure that a C++ compiler is installed before you can proceed (for example, Microsoft Visual C++, v6.0 or higher). To use the UDRGM you must first build the UDRGM library by compiling your UDRGM C code and then load the library into the ANSYS Fluent code. The UDRGM shared library is built in the same way that the ANSYS Fluent executable itself is built. Internally, a script called Makefile is used to invoke the system C compiler to build an object code library that contains the native machine language translation of your higher-level C source code. This shared library is then loaded into ANSYS Fluent (either at runtime or automatically when a case file is read) by a process called **dynamic loading**. The object libraries are specific to the computer architecture being used, as well as to the particular version of the ANSYS Fluent executable being run. The libraries must, therefore, be rebuilt any time ANSYS Fluent is upgraded, when the computer’s operating system level changes, or when the job is run on a different type of computer. The general procedure for compiling UDRGM C code is as follows:

- Place the UDRGM C code in the folder, that is, where your case file resides.

---

Release 15.0 - © SAS IP Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

498
• Launch ANSYS Fluent.

• Read your case file into ANSYS Fluent.

• You can now compile your UDRGM C code and build a shared library file using either the graphical interface or the text command interface.

  **Important**

  To build UDRGM library you will use the compiled UDF utilities. However, you will not use the UDF utilities to load the library. A separate loading area for the UDRGM library will be used.

### 7.16.5.3.1. Compiling the UDRGM Using the Graphical Interface

If the build is successful, then the compiled library will be placed in the appropriate architecture folder (for example, nt64/2d). By default the library name is libudf.so (libudf.dll on Windows).

More information on compiled UDFs and building libraries using the ANSYS Fluent graphical user interface can be found in the **UDF Manual**.

### 7.16.5.3.2. Compiling the UDRGM Using the Text Interface

The UDRGM library can be compiled in the text command interface as follows:

• Select the menu item define → user-defined → compiled-functions.

• Select the compile option.

• Enter the compiled UDF library name.

  **Important**

  The name given here is the name of the folder where the shared library (for example, libudf) will reside. For example, if you press **Enter** then a folder should exist with the name libudf, and this folder will contain a library file called libudf. If, however, you type a new library name such as myrealgas, then a folder called myrealgas will be created and it will contain the library libudf.

• Continue on with the procedure when prompted.

• Enter the C source file names.

  **Important**

  Ideally you should place all of your functions into a single file. However, you can split them into separate files if desired.

• Enter the header file names, if applicable. If you do not have an extra header file then press **Enter** when prompted.
ANSYS Fluent will then start compiling the UDRGM C code and put it in the appropriate architecture folder.

Example:

```plaintext
> define/user-defined/compiled-functions
load OR compile ? [load]  compile

Compiled UDF library name: ["libudf"]  my_lib

Make sure that UDF source files are in the folder that contains your case and data files. If you have an existing libudf folder, please remove this folder to ensure that latest files are used.

Continue? [yes] RETURN

Give C-Source file names:
First file name: ["]  my_c_file.c RETURN

Next file name: ["]  RETURN

Give header file names:
First file name: ["]  my_header_file.h RETURN

7.16.5.3.3. Loading the UDRGM Shared Library File

Load the UDRGM library:

• Go to the following menu item in the text command interface.
  define → user-defined → real-gas-models

• Select one of the following
  - user-defined-real-gas-model if you are modeling a single-species real gas fluid
  - user-defined-multispecies-real-gas-model if you are modeling a multiple-species fluid-mixture

• Turn on the real gas model.
  - For single-species:
    use user defined real gas? [no]  yes
  - For multiple-species:
    use multispecies user defined real gas? [no]  yes

ANSYS Fluent will ask for the location of the user-defined real gas library. You can enter either the name of the folder where the UDRGM shared library is called or the entire path to the UDRGM shared library.

If the loading of the UDRGM library is successful you will see a message similar to the following:

Opening user-defined realgas library "RealgasLibraryname"...
Library "RealgasDirName/1namd64/2d/libudf.so" opened
Setting material "air" to a real-gas...
Loading Real-RealGasPrefixLabel Library:
7.16.5.4. UDRGM Example: Ideal Gas Equation of State

This section describes an example of a user-defined real gas model. You can use this example as the basis for your own UDRGM code. In this simple example, the standard ideal gas equation of state is used in the UDRGM. See User-Defined Real Gas Models (UDRGM) in the UDF Manual for more examples of UDRGM functions, including multi-species real gas and reacting real-gas examples.

\[
p = \text{pressure} \\
T = \text{temperature} \\
C_p = \text{specific heat} \\
H = \text{enthalpy} \\
S = \text{entropy} \\
\rho = \text{density} \\
c = \text{speed of sound} \\
R = \text{universal gas constant/molecular weight}
\]

The ideal gas equation of state can be written in terms of pressure and temperature as

\[
\rho = \frac{p}{RT}
\]

(7.114)

The specific heat is defined to be constant \( C_p = 1006.42 \).

The enthalpy is, therefore, defined as

\[
H = C_p T
\]

(7.115)

and entropy is given by

\[
S = C_p \log \left( \frac{T}{T_{ref}} \right) + R \log \left( \frac{p_{ref}}{p} \right)
\]

(7.116)

where \( T_{ref} = 288.15 \text{ K} \) and \( p_{ref} = 101325 \text{ Pa} \)

The speed of sound is simply defined as

\[
c = \sqrt{C_p \frac{R}{(C_p - R)}}
\]

(7.117)

The density derivatives are:

\[
\left( \frac{d\rho}{dp} \right)_T = \frac{1}{RT}
\]

(7.118)

\[
\left( \frac{d\rho}{dT} \right)_p = -\frac{p}{RT^2} = -\frac{\rho}{T}
\]

(7.119)

The enthalpy derivatives are:
Physical Properties

\[
\left( \frac{dH}{dT} \right)_p = C_p \\
\left( \frac{dH}{dp} \right)_T = \frac{C_p}{\rho R} \left[ 1 - \frac{p}{\rho \frac{dp}{d\rho}} \right] = 0
\] (7.120) (7.121)

When you activate the real gas model and load the library successfully into ANSYS Fluent, you will be using the equation of state and other fluid properties from this library rather than the one built into the ANSYS Fluent code.

7.16.5.5. Additional UDRGM Examples

You can find the following additional UDRGM examples in the UDF Manual:

- The Aungier Redlich Kwong equation of state for single component flow. See UDRGM Example: Redlich-Kwong Equation of State in the UDF Manual for details.

- A simple example of a multi-species real-gas model. See UDRGM Example: Multiple-Species Real Gas Model in the UDF Manual for details.

- A real gas model example with the Aungier Redlich Kwong equation of state, ideal gas mixing rules and volumetric reactions. See UDRGM Example: Real Gas Model with Volumetric Reactions in the UDF Manual for details.
Chapter 8: Modeling Basic Fluid Flow

This chapter describes the basic physical models that ANSYS Fluent provides for fluid flow and the commands for defining and using them. Models for flows in moving zones (including sliding and dynamic meshes) are explained in Modeling Flows with Moving Reference Frames (p. 535), models for turbulence are described in Modeling Turbulence (p. 695), and models for heat transfer (including radiation) are presented in Modeling Heat Transfer (p. 759). An overview of modeling species transport and reacting flows is provided in Modeling Species Transport and Finite-Rate Chemistry (p. 885), details about models for species transport and reacting flows are described in Modeling Species Transport and Finite-Rate Chemistry (p. 885) – Modeling a Composition PDF Transport Problem (p. 1025), and models for pollutant formation are described in Modeling Pollutant Formation (p. 1065). The discrete phase model is described in Modeling Discrete Phase (p. 1131), general multiphase models are described in Modeling Multiphase Flows (p. 1243), and the melting and solidification model is described in Modeling Solidification and Melting (p. 1389). For information on modeling porous media, porous jumps, and lumped parameter fans and radiators, see Cell Zone and Boundary Conditions (p. 201).

The information in this chapter is presented in the following sections:
8.1. User-Defined Scalar (UDS) Transport Equations
8.2. Periodic Flows
8.3. Swirling and Rotating Flows
8.4. Compressible Flows
8.5. Inviscid Flows

8.1. User-Defined Scalar (UDS) Transport Equations

For additional information, see the following sections:
8.1.1. Introduction
8.1.2. UDS Theory
8.1.3. Setting Up UDS Equations in ANSYS Fluent

8.1.1. Introduction

ANSYS Fluent can solve the transport equation for an arbitrary, user-defined scalar (UDS) in the same way that it solves the transport equation for a scalar such as species mass fraction. Extra scalar transport equations may be needed in certain types of combustion applications or for example in plasma-enhanced surface reaction modeling. ANSYS Fluent allows you to define additional scalar transport equations in your model in the User-Defined Scalars Dialog Box (p. 2456).

8.1.2. UDS Theory

UDS theory is described in the following sections:
8.1.2.1. Single Phase Flow
8.1.2.2. Multiphase Flow
8.1.2.1. Single Phase Flow

For an arbitrary scalar $\phi_k$, ANSYS Fluent solves the equation

$$\frac{\partial \rho \phi_k}{\partial t} + \frac{\partial}{\partial x_i} \left( \rho u_i \phi_k \Gamma_k \frac{\partial \phi_k}{\partial x_i} \right) = S_{\phi_k} \quad k = 1, \ldots, N$$

(8.1)

where $\Gamma_k$ and $S_{\phi_k}$ are the diffusion coefficient and source term supplied by you for each of the $N$ scalar equations. Note that $\Gamma_k$ is defined as a tensor in the case of anisotropic diffusivity. The diffusion term is therefore $\nabla \cdot \left( \Gamma_k \cdot \phi_k \right)$.

For isotropic diffusivity, $\Gamma_k$ could be written as $\Gamma_k I$ where I is the identity matrix.

For the steady-state case, ANSYS Fluent will solve one of the three following equations, depending on the method used to compute the convective flux:

- If convective flux is not to be computed, ANSYS Fluent will solve the equation
  $$- \frac{\partial}{\partial x_i} \left( \Gamma_k \frac{\partial \phi_k}{\partial x_i} \right) = S_{\phi_k} \quad k = 1, \ldots, N$$
  (8.2)

  where $\Gamma_k$ and $S_{\phi_k}$ are the diffusion coefficient and source term supplied by you for each of the $N$ scalar equations.

- If convective flux is to be computed with mass flow rate, ANSYS Fluent will solve the equation
  $$\frac{\partial}{\partial x_i} \left( \rho u_i \phi_k \Gamma_k \frac{\partial \phi_k}{\partial x_i} \right) = S_{\phi_k} \quad k = 1, \ldots, N$$
  (8.3)

- It is also possible to specify a user-defined function to be used in the computation of convective flux. In this case, the user-defined mass flux is assumed to be of the form
  $$F = \int_S \rho \vec{u} \cdot d\vec{S}$$
  (8.4)

where $d\vec{S}$ is the face vector area.

**Important**

User-defined scalars in solid zones do not take into account the convective term with moving reference frames.

8.1.2.2. Multiphase Flow

For multiphase flows, ANSYS Fluent solves transport equations for two types of scalars: *per phase* and *mixture*. For an arbitrary $k$ scalar in *phase-1*, denoted by $\phi^k_1$, ANSYS Fluent solves the transport equation inside the volume occupied by *phase-1*
\[ \frac{\partial \alpha_l \rho_l \phi_l^k}{\partial t} + \nabla \cdot \left( \alpha_l \rho_l \vec{u}_l \cdot \phi_l^k - \alpha_l \Gamma_l^k \nabla \phi_l^k \right) = S_l^k \quad k = 1, \ldots, N \]  \hspace{1cm} (8.5)

where \( \alpha_l, \rho_l \) and \( \vec{u}_l \) are the volume fraction, physical density, and velocity of phase-\( l \), respectively. \( \Gamma_l^k \) and \( S_l^k \) are the diffusion coefficient and source term, respectively, which you will need to specify. In this case, scalar \( \phi_l^k \) is associated only with one phase (phase-\( l \)) and is considered an individual field variable of phase-\( l \).

The mass flux for phase-\( l \) is defined as
\[ F_l = \int_S \alpha_l \rho_l \vec{u}_l \cdot \hat{n} \, dS \]  \hspace{1cm} (8.6)

If the transport variable described by scalar \( \phi_l^k \) represents the physical field that is shared between phases, or is considered the same for each phase, then you should consider this scalar as being associated with a mixture of phases, \( \phi^k \). In this case, the generic transport equation for the scalar is
\[ \frac{\partial \rho_m \phi^k}{\partial t} + \nabla \cdot \left( \rho_m \vec{u}_m \phi^k - \Gamma_m^k \nabla \phi^k \right) = S_m^k \quad k = 1, \ldots, N \]  \hspace{1cm} (8.7)

where mixture density \( \rho_m \), mixture velocity \( \vec{u}_m \), and mixture diffusivity for the scalar \( k \) \( \Gamma_m^k \) are calculated according to
\[ \rho_m = \sum_l \alpha_l \rho_l \]  \hspace{1cm} (8.8)
\[ \rho_m \vec{u}_m = \sum_l \alpha_l \rho_l \vec{u}_l \]  \hspace{1cm} (8.9)
\[ F_m = \int_S \rho_m \vec{u}_m \cdot \hat{n} \, dS \]  \hspace{1cm} (8.10)
\[ \Gamma_m^k = \sum_l \alpha_l \Gamma_l^k \]  \hspace{1cm} (8.11)
\[ S_m^k = \sum_l S_l^k \]  \hspace{1cm} (8.12)

To calculate mixture diffusivity, you must specify individual diffusivities for each material associated with individual phases.

Note that if the user-defined mass flux option is activated, then mass fluxes shown in Equation 8.6 (p. 507) and Equation 8.10 (p. 507) must be replaced in the corresponding scalar transport equations. For more information about the theoretical background of user-defined scalar transport equations, see User-Defined Scalar (UDS) Transport Equations in the Theory Guide.

### 8.1.3. Setting Up UDS Equations in ANSYS Fluent

ANSYS Fluent allows you to define up to 50 user-defined scalar (UDS) transport equations in your model. The general scalar transport equation, Equation 1.8 in the Theory Guide, is shown below with the four terms (transient, flux, diffusivity, source) that you can customize. (Equation 8.13 (p. 508)). You will define a UDS transport equation by setting the parameters for these four terms.
\[
\frac{\partial \rho \phi_k}{\partial t} + \frac{\partial}{\partial x_i} \left( F_i \phi_k - \Gamma_k \frac{\partial \phi_k}{\partial x_i} \right) = S_{\phi_k} \quad k = 1, \ldots, N_{\text{scalars}} \tag{8.13}
\]

In addition, you can set boundary conditions for the variables within cells of a fluid or solid zone for a particular scalar equation. This is done by fixing the value of \( \phi_k \) in Equation 8.13 (p. 508). When \( \phi_k \) is fixed in a given cell, the UDS scalar transport is not solved and the cell is not included when the residual sum is computed. Additionally, you can also specify custom boundary conditions in the mixture on all wall, inflow, and outflow boundaries on a per-scalar basis.

The procedures for setting up a user-defined scalar (UDS) equation for single-phase and multiphase flows are outlined below. Note that a significant difference between a UDS for a single-phase versus a multiphase application is that you must associate each UDS with its corresponding phase domain or mixture domain, depending on your application. If you supply UDFs for transient terms, convective fluxes, and sources, you must be aware that they are directly called from the phase or mixture domains, according to the scalar association settings.

See the UDF Manual for information on using UDFs to define scalar quantities.

### 8.1.3.1. Single Phase Flow

1. Specify the number of UDS equations you require in the User-Defined Scalars Dialog Box (p. 2456) (Figure 8.1: The User-Defined Scalars Dialog Box (p. 509)).

   **Define → User-Defined → Scalars...**

   **Important**

   The maximum number of user-defined scalar transport equations you can define is 50. ANSYS Fluent assigns numbers to the equations starting with 0.

   **Important**

   Note that ANSYS Fluent assigns a default name for each scalar equation (User Scalar 0, User Scalar 1, etc.). These labels will appear in graphics dialog boxes in ANSYS Fluent. You can change them by means of a UDF. See the UDF Manual for details.
2. Enable **Inlet Diffusion** if you want to include the diffusion term in the UDS transport equation for all inflow and outflow boundaries.

3. Set the first user-defined scalar equation parameters by making sure that the **UDS Index** is set to 0.
   a. Specify the **Solution Zones** you want the scalar equation to be solved in as **all fluid zones, all solid zones, all zones** (fluid and solid) or **selected zones**. If you choose **selected zones**, click the **Edit** button to view the list of zones you can select.

   b. Specify the **Flux Function** to be **none, mass flow rate**, or a user-defined function (UDF). The **Flux Function** determines how the convective flux is computed, which determines the equation that ANSYS Fluent solves for the user-defined scalar. Selecting **none, mass flow rate**, or a user-defined function results in ANSYS Fluent solving **Equation 1.9**, **Equation 1.10**, or **Equation 1.11**, respectively (in the **Theory Guide**). See the **UDF Manual** for details on flux UDFs.

   c. Specify the **Unsteady Function** to be **none, default**, or a user-defined function (UDF). Select **none** for a steady state solution and **default** if you want the transient term in **Equation 1.8** in the **Theory Guide**. See the separate **UDF Manual** for details on unsteady UDFs.

   d. Repeat this process for each scalar equation by incrementing the **UDS Index**.

   e. Click **OK** when all user scalar equations have been defined.

4. To specify source term(s) for each of the \( N \) UDS equations, enable the **Source Terms** option in the **Fluid** or **Solid** dialog box (Figure 8.2: The Fluid Dialog Box with Inputs for Source Terms for a User-Defined Scalar (p. 510)) and click the **Source Terms** tab. The source parameters will be displayed.

**Cell Zone Conditions**
Figure 8.2: The Fluid Dialog Box with Inputs for Source Terms for a User-Defined Scalar

Figure 8.3: The User Scalar Sources Dialog Box

a. Specify the number of sources you require for each scalar equation by clicking on the Edit... button next to the scalar name (for example, User Scalar 0). This will open the User Scalar 0 sources dialog box (Figure 8.3: The User Scalar Sources Dialog Box (p. 510)).
b. Specify the **Number of User Scalar Sources** for the scalar equation by incrementing the counter. Based on the value you have chosen, the sources will be added to the list in the dialog box. Specify each source to be **none, constant**, or a user-defined function (UDF). For details on defining a UDF scalar source, see the **UDF Manual**. Click **OK** when you have specified all scalar sources.

5. To specify diffusivity for each of the $N$ UDS equations, display the **Materials Task Page** (p. 2020) (Figure 8.4: The Materials Dialog Box with Input for Diffusivity for UDS Equations (p. 511)) and select either **defined-per-uds** (the default) or **user-defined** in the drop-down list for **UDS Diffusivity**.

![Figure 8.4: The Materials Dialog Box with Input for Diffusivity for UDS Equations](image)

See **User-Defined Scalar (UDS) Diffusivity** (p. 443) for details on the different options available to you for defining diffusion coefficients.

6. To specify boundary conditions for the user-defined scalars on wall, inflow, and outflow boundaries, you can define a specific value or a specific flux for each scalar. A coupled boundary condition can be specified on two-sided walls for scalars that are to be solved in regions on both sides of the wall (that is, scalars solved in both **fluid and solid** zones).

**Boundary Conditions**

a. In the **UDS** tab under **User Defined Scalar Boundary Condition**, select either **Specified Flux** or **Specified Value** in the drop-down list next to each scalar (for example, **User Scalar 0** for a boundary wall. For interior walls, select **Coupled Boundary** if the scalars are to be solved on both sides of a
two-sided wall. Note that the **Coupled Boundary** option will only show up in the drop-down list if the scalar is defined in the **fluid and solid** zones in the User-Defined Scalars Dialog Box (p. 2456).

b. Under **User Defined Scalar Boundary Value**, enter a constant value or select a user-defined function from the drop-down list for each scalar. If you select **Specified Flux**, your input will be the value of the flux at the boundary (that is, the negative of the term in parenthesis on the left-hand side of in the Theory Guide) dot [as in the dot product of] \( n \) [as in the vector, \( n \)], where \( n \) is the normal into the domain). If you select **Specified Value**, your input will be the value of the scalar itself at the boundary. See the UDF Manual for information on using UDFs for UDS boundary conditions.

7. Set the solution parameters in the **Solution Controls** task page, specify an initial value for each UDS (as you do for all other scalar transport equations), and calculate a solution.

8. Examine the results using the usual postprocessing tools. In each postprocessing dialog box, the list of field variables will include the **User Defined Scalars...** category, which contains the value of each UDS and its diffusion coefficient (\( J_k \) in Equation 1.8, Equation 1.9, Equation 1.10, or Equation 1.11 (in the Theory Guide):

- **User Scalar-n**
- **Diffusion Coef. of Scalar-n**

### 8.1.3.2. Multiphase Flow

1. Specify the number of scalars in the User-Defined Scalars Dialog Box (p. 2456) (Figure 8.5: The User-Defined Scalars Dialog Box for a Multiphase Flow (p. 513)).

   Define → User-Defined → Scalars...
Figure 8.5: The User-Defined Scalars Dialog Box for a Multiphase Flow

**Important**

The maximum number of user-defined scalar transport equations you can define is 50. ANSYS Fluent assigns numbers to the equations starting with 0. The default association type is set to `mixture` for all scalars.

**Important**

Note that ANSYS Fluent assigns a default name for each scalar equation (User Scalar 0, User Scalar 1, etc.). These labels will appear in graphics dialog boxes in ANSYS Fluent. You can change them by means of a UDF. See the UDF Manual for details.

2. Keep the default **Inlet Diffusion** enabled if you want to include the diffusion term in the UDS transport equation for all inflow and outflow boundaries.

3. Set the first user-defined scalar equation parameters by making sure that the **UDS Index** is set to 0.
   a. Select the **Phase** you want the scalar equation solved in as a primary phase, secondary phase, or the mixture.
   b. Specify the **Solution Zones** you want the scalar equation to be solved in as all fluid zones, all solid zones, all zones (fluid and solid) or selected zones. If you choose selected zones, click the **Edit** button to view the list of zones you can select.
   c. Specify the **Flux Function** to **Unsteady Function** the same way as you would for a single phase flow (see above).
   d. Repeat this process for each scalar equation by incrementing the **UDS Index**.
   e. Click **OK** when all user scalar equations have been defined.
4. Specify source term(s) for each of the \(N\) UDS equations in the Fluid or Solid dialog box as described for a single phase flow (see above).

5. Specify boundary conditions for the user-defined scalars in the mixture on all wall, inflow, and outflow boundary as described for a single phase flow (see above).

6. Set the solution parameters, specify an initial value for each UDS (as you do for all other scalar transport equations), and calculate a solution.

### 8.2. Periodic Flows

Periodic flow occurs when the physical geometry of interest and the expected pattern of the flow/thermal solution have a periodically repeating nature. Two types of periodic flow can be modeled in ANSYS Fluent. In the first type, no pressure drop occurs across the periodic planes. In the second type, a pressure drop occurs across translationally periodic boundaries, resulting in “fully-developed” or “streamwise-periodic” flow.

This section discusses streamwise-periodic flow. A description of no-pressure-drop periodic flow is provided in Periodic Boundary Conditions (p. 332), and a description of streamwise-periodic heat transfer is provided in Modeling Periodic Heat Transfer (p. 840).

Information about streamwise-periodic flow is presented in the following sections:

- 8.2.1. Overview and Limitations
- 8.2.2. User Inputs for the Pressure-Based Solver
- 8.2.3. User Inputs for the Density-Based Solvers
- 8.2.4. Monitoring the Value of the Pressure Gradient
- 8.2.5. Postprocessing for Streamwise-Periodic Flows

For more information about the theoretical background of periodic flows, see Periodic Flows in the Theory Guide.

### 8.2.1. Overview and Limitations

More information about periodic flows is presented in the following sections:

- 8.2.1.1. Overview
- 8.2.1.2. Limitations for Modeling Streamwise-Periodic Flow

#### 8.2.1.1. Overview

ANSYS Fluent provides the ability to calculate streamwise-periodic—or “fully-developed”—fluid flow. These flows are encountered in a variety of applications, including flows in compact heat exchanger channels and flows across tube banks. In such flow configurations, the geometry varies in a repeating manner along the direction of the flow, leading to a periodic fully-developed flow regime in which the flow pattern repeats in successive cycles. Other examples of streamwise-periodic flows include fully-developed flow in pipes and ducts. These periodic conditions are achieved after a sufficient entrance length, which depends on the flow Reynolds number and geometric configuration.

Streamwise-periodic flow conditions exist when the flow pattern repeats over some length \(L\), with a constant pressure drop across each repeating module along the streamwise direction. Figure 8.6: Example of Periodic Flow in a 2D Heat Exchanger Geometry (p. 515) depicts one example of a periodically repeating flow of this type that has been modeled by including a single representative module.
8.2.1.2. Limitations for Modeling Streamwise-Periodic Flow

The following limitations apply to modeling streamwise-periodic flow:

- The flow must be incompressible.

- When performing unsteady-state simulations with translational periodic boundary conditions, the specified pressure gradient is recommended.

- If one of the density-based solvers is used, you can specify only the pressure jump; for the pressure-based solver, you can specify either the pressure jump or the mass flow rate.

- No net mass addition through inlets/exits or extra source terms is allowed.

- Species can be modeled only if inlets/exits (without net mass addition) are included in the problem. Reacting flows are not permitted.

- Steady particle tracks can be modeled only if the particles have a possibility to leave the domain without generating incomplete trajectories.

- While Eulerian multiphase can be modeled with translational periodic boundary conditions, you cannot use the mass flow rate specification method. However, you can specify a constant pressure gradient.

8.2.2. User Inputs for the Pressure-Based Solver

If you are using the pressure-based solver, in order to calculate a spatially periodic flow field with a specified mass flow rate or pressure derivative, you must first create a mesh with translationally periodic boundaries that are parallel to each other and equal in size. You can specify translational periodicity in the Periodic Conditions Dialog Box (p. 2170), as described in Periodic Boundary Conditions (p. 332). (If you need to create periodic boundaries, see Creating Conformal Periodic Zones (p. 184)).
In the Periodic Conditions Dialog Box (p. 2170) that is opened from the Boundary Conditions Task Page (p. 2102), you will complete the following inputs after the mesh has been read into ANSYS Fluent (Figure 8.7: The Periodic Conditions Dialog Box (p. 516)):

**Boundary Conditions → Periodic Conditions...**

**Figure 8.7: The Periodic Conditions Dialog Box**

1. Select either the specified mass flow rate (Specify Mass Flow) option or the specified pressure gradient (Specify Pressure Gradient) option. For most problems, the mass flow rate across the periodic boundary will be a known quantity; for others, the mass flow rate will be unknown, but the pressure gradient ($\beta$ in Equation 1.22, in the Theory Guide) will be a known quantity.

2. Specify the mass flow rate and/or the pressure gradient ($\beta$ in Equation 1.22, in the Theory Guide):
   - If you selected the Specify Mass Flow option, enter the desired value for the Mass Flow Rate. You can also specify an initial guess for the Pressure Gradient, but this is not required.

     **Important**

     For axisymmetric problems, the mass flow rate is per $2\pi$ radians.

     • If you selected the Specify Pressure Gradient option, enter the desired value for Pressure Gradient.

3. Define the flow direction by setting the $X, Y, Z$ (or $X, Y$ in 2D) point under Flow Direction. The flow will move in the direction of the vector pointing from the origin to the specified point. The direction vector must be parallel to the periodic translation direction or its opposite.

4. If you chose in step 1 to specify the mass flow rate, set the parameters used for the calculation of $\beta$. These parameters are described in detail below.

After completing these inputs, you can solve the periodic velocity field to convergence.
8.2.2.1. Setting Parameters for the Calculation of $\beta$

If you choose to specify the mass flow rate, ANSYS Fluent must calculate the appropriate value of the pressure gradient $\beta$. You can control this calculation by specifying the Relaxation Factor and the Number of Iterations, and by supplying an initial guess for $\beta$. All of these inputs are entered in the Periodic Conditions Dialog Box (p. 2170).

The Number of Iterations sets the number of sub-iterations performed on the correction of $\beta$ in the pressure correction equation. Because the value of $\beta$ is not known a priori, it must be iterated on until the Mass Flow Rate that you have defined is achieved in the computational model. This correction of $\beta$ occurs in the pressure correction step of the SIMPLE, SIMPLEC, or PISO algorithm. A correction to the current value of $\beta$ is calculated based on the difference between the desired mass flow rate and the actual one. The sub-iterations referred to here are performed within the pressure correction step to improve the correction for $\beta$ before the pressure correction equation is solved for the resulting pressure (and velocity) correction values. The default value of 2 sub-iterations should suffice in most problems, but can be increased to help speed convergence. The Relaxation Factor is an under-relaxation factor that controls convergence of this iteration process.

You can also speed up convergence of the periodic calculation by supplying an initial guess for $\beta$ in the Pressure Gradient field. Note that the current value of $\beta$ will be displayed in this field if you have performed any calculations. To update the Pressure Gradient field with the current value at any time, click the Update button.

8.2.3. User Inputs for the Density-Based Solvers

If you are using one of the density-based solvers, in order to calculate a spatially periodic flow field with a specified pressure jump, you must first create a mesh with translationally periodic boundaries that are parallel to each other and equal in size. (If you need to create periodic boundaries, see Creating Conformal Periodic Zones (p. 184).)

Then, follow the steps below:

1. In the Periodic Dialog Box (p. 2135) (Figure 8.8: The Periodic Dialog Box (p. 518)), which is opened from the Boundary Conditions task page, indicate that the periodicity is Translational (the default).
After completing these inputs, you can solve the periodic velocity field to convergence.

### 8.2.4. Monitoring the Value of the Pressure Gradient

If you have specified the mass flow rate, you can monitor the value of the pressure gradient $\beta$ during the calculation using the Statistic Monitors Dialog Box (p. 2225). Select $\text{per/pr-grad}$ as the variable to be monitored. See Monitoring Statistics (p. 1486) for details about using this feature.

### 8.2.5. Postprocessing for Streamwise-Periodic Flows

For streamwise-periodic flows, the velocity field should be completely periodic. If a density-based solver is used to compute the periodic flow, the pressure field reported will be the actual pressure $p$ (which is not periodic). If the pressure-based solver is used, the pressure field reported will be the periodic pressure field $\tilde{p}$ (\(\vec{F}\)) of Equation 1.22, in the Theory Guide. Figure 8.9: Periodic Pressure Field Predicted for Flow in a 2D Heat Exchanger Geometry (p. 519) displays the periodic pressure field in the geometry of Figure 8.6: Example of Periodic Flow in a 2D Heat Exchanger Geometry (p. 515).

If you specified a mass flow rate and had ANSYS Fluent calculate the pressure gradient, you can check the pressure gradient in the streamwise direction ($\beta$) by looking at the current value for Pressure Gradient in the Periodic Conditions Dialog Box (p. 2170).
8.3. Swirling and Rotating Flows

Many important engineering flows involve swirl or rotation and ANSYS Fluent is well-equipped to model such flows. Swirling flows are common in combustion, with swirl introduced in burners and combustors in order to increase residence time and stabilize the flow pattern. Rotating flows are also encountered in turbomachinery, mixing tanks, and a variety of other applications.

Information about rotating and swirling flows is provided in the following subsections:

8.3.1. Overview of Swirling and Rotating Flows
8.3.2. Turbulence Modeling in Swirling Flows
8.3.3. Mesh Setup for Swirling and Rotating Flows
8.3.4. Modeling Axisymmetric Flows with Swirl or Rotation

For more information about the theoretical background of swirling and rotating flows, see Swirling and Rotating Flows in the Theory Guide.

When you begin the analysis of a rotating or swirling flow, it is essential that you classify your problem into one of the following five categories of flow:

- axisymmetric flows with swirl or rotation
- fully three-dimensional swirling or rotating flows
- flows requiring a moving reference frame
- flows requiring multiple moving reference frames or mixing planes
- flows requiring sliding meshes

Modeling and solution procedures for the first two categories are presented in this section. The remaining three, which all involve “moving zones,” are discussed in Modeling Flows with Moving Reference Frames (p. 535).
8.3.1. Overview of Swirling and Rotating Flows

An overview of swirling and rotating flows is presented in the following sections:
- 8.3.1.1. Axisymmetric Flows with Swirl or Rotation
- 8.3.1.2. Three-Dimensional Swirling Flows
- 8.3.1.3. Flows Requiring a Moving Reference Frame

8.3.1.1. Axisymmetric Flows with Swirl or Rotation

Your problem may be axisymmetric with respect to geometry and flow conditions but still include swirl or rotation. In this case, you can model the flow in 2D (that is, solve the axisymmetric problem) and include the prediction of the circumferential (or swirl) velocity. It is important to note that while the assumption of axisymmetry implies that there are no circumferential gradients in the flow, there may still be non-zero swirl velocities.

8.3.1.1.1. Momentum Conservation Equation for Swirl Velocity

The tangential momentum equation for 2D swirling flows may be written as

\[
\frac{\partial}{\partial t} (\rho w) + \frac{1}{r} \frac{\partial}{\partial x} (r \rho u w) + \frac{1}{r} \frac{\partial}{\partial r} (r \rho v w) = \frac{1}{r} \frac{\partial}{\partial x} \left[ \frac{\partial w}{\partial x} \right] \\
+ \frac{1}{r^2} \frac{\partial}{\partial r} \left[ r^3 \mu \frac{\partial}{\partial r} \left( \frac{w}{r} \right) \right] - \frac{\rho w}{r}
\]

(8.14)

where \( x \) is the axial coordinate, \( r \) is the radial coordinate, \( u \) is the axial velocity, \( v \) is the radial velocity, and \( w \) is the swirl velocity.

8.3.1.2. Three-Dimensional Swirling Flows

When there are geometric changes and/or flow gradients in the circumferential direction, your swirling flow prediction requires a three-dimensional model. If you are planning a 3D ANSYS Fluent model that includes swirl or rotation, you should be aware of the setup constraints listed in Coordinate System Restrictions (p. 521). In addition, you might consider simplifications to the problem that might reduce it to an equivalent axisymmetric problem, especially for your initial modeling effort. Because of the complexity of swirling flows, an initial 2D study, in which you can quickly determine the effects of various modeling and design choices, can be very beneficial.

---

Important

For 3D problems involving swirl or rotation, there are no special inputs required during the problem setup and no special solution procedures. Note, however, that you may want to use the cylindrical coordinate system for defining velocity-inlet boundary condition inputs, as described in Defining the Velocity (p. 272). Also, you may find the gradual increase of the rotational speed (set as a wall or inlet boundary condition) helpful during the solution process. This is described for axisymmetric swirling flows in Improving Solution Stability by Gradually Increasing the Rotational or Swirl Speed (p. 524).

8.3.1.3. Flows Requiring a Moving Reference Frame

If your flow involves a rotating boundary that moves through the fluid (for example, an impeller blade or a grooved or notched surface), you must use a moving reference frame to model the problem. Such
applications are described in detail in Introduction (p. 535). If you have more than one rotating boundary (for example, several impellers in a row), you can use multiple reference frames (described in The Multiple Reference Frame Model (p. 545)) or mixing planes (described in The Mixing Plane Model (p. 547)).

8.3.2. Turbulence Modeling in Swirling Flows

If you are modeling turbulent flow with a significant amount of swirl (for example, cyclone flows, swirling jets), you should consider using one of ANSYS Fluent’s advanced turbulence models: the RNG k-ε model, realizable k-ε model, or Reynolds stress model. The appropriate choice depends on the strength of the swirl, which can be gauged by the swirl number. The swirl number is defined as the ratio of the axial flux of angular momentum to the axial flux of axial momentum:

\[
S = \frac{\int r w \bar{v} \cdot dA}{\bar{R} \int u \bar{v} \cdot dA}
\]  

(8.15)

where \( \bar{R} \) is the hydraulic radius.

For flows with weak to moderate swirl (\( S < 0.5 \)), both the RNG k-ε model and the realizable k-ε model yield appreciable improvements over the standard k-ε model. See RNG k-ε Model and Realizable k-ε Model Swirl Modification (p. 737) for details about these models.

For highly swirling flows (\( S > 0.5 \)), the Reynolds stress model (RSM) is strongly recommended. The effects of strong turbulence anisotropy can be modeled rigorously only by the second-moment closure adopted in the RSM. See Reynolds Stress Model (RSM) Steps in Using a Turbulence Model (p. 709) for details about this model.

For swirling flows encountered in devices such as cyclone separators and swirl combustors, near-wall turbulence modeling is quite often a secondary issue at most. The fidelity of the predictions in these cases is mainly determined by the accuracy of the turbulence model in the core region. However, in cases where walls actively participate in the generation of swirl (that is, where the secondary flows and vortical flows are generated by pressure gradients), non-equilibrium wall functions can often improve the predictions since they use a law of the wall for mean velocity sensitized to pressure gradients. See Near-Wall Treatments for Wall-Bounded Turbulent Flows in the Theory Guide for additional details about near-wall treatments for turbulence.

8.3.3. Mesh Setup for Swirling and Rotating Flows

8.3.3.1. Coordinate System Restrictions

Recall that for an axisymmetric problem, the axis of rotation must be the \( x \) axis and the mesh must lie on or above the \( y = 0 \) line.

8.3.3.2. Mesh Sensitivity in Swirling and Rotating Flows

In addition to the setup constraint described above, you should be aware of the need for sufficient resolution in your mesh when solving flows that include swirl or rotation. Typically, rotating boundary layers may be very thin, and your ANSYS Fluent model will require a very fine mesh near a rotating wall. In addition, swirling flows will often involve steep gradients in the circumferential velocity (for example, near the centerline of a free-vortex type flow), and therefore require a fine mesh for accurate resolution.
8.3.4. Modeling Axisymmetric Flows with Swirl or Rotation

As discussed in Overview of Swirling and Rotating Flows (p. 520), you can solve a 2D axisymmetric problem that includes the prediction of the circumferential or swirl velocity. The assumption of axisymmetry implies that there are no circumferential gradients in the flow, but that there may be non-zero circumferential velocities. Examples of axisymmetric flows involving swirl or rotation are depicted in Figure 8.10: Rotating Flow in a Cavity (p. 522) and Figure 8.11: Swirling Flow in a Gas Burner (p. 522).

Figure 8.10: Rotating Flow in a Cavity

![Rotating Flow in a Cavity](image)

Figure 8.11: Swirling Flow in a Gas Burner

![Swirling Flow in a Gas Burner](image)

8.3.4.1. Problem Setup for Axisymmetric Swirling Flows

For axisymmetric problems, you must perform the following steps during the problem setup procedure. (Only those steps relevant specifically to the setup of axisymmetric swirl/rotation are listed here. You must set up the rest of the problem as usual.)
1. Activate solution of the momentum equation in the circumferential direction by turning on the **Axisymmetric Swirl** option for **Space** in the **General** task page.

   ![General](General) → ![Axisymmetric](Axisymmetric)

2. Define the rotational or swirling component of velocity, \( r\Omega \), at inlets or walls.

   ![Boundary Conditions](Important)

   **Important**

   Remember to use the axis boundary type for the axis of rotation.

The procedures for input of rotational velocities at inlets and at walls are described in detail in **Defining the Velocity** (p. 272) and **Velocity Conditions for Moving Walls** (p. 311).

### 8.3.4.2. Solution Strategies for Axisymmetric Swirling Flows

The difficulties associated with solving swirling and rotating flows are a result of the high degree of coupling between the momentum equations, which is introduced when the influence of the rotational terms is large. A high level of rotation introduces a large radial pressure gradient that drives the flow in the axial and radial directions. This, in turn, determines the distribution of the swirl or rotation in the field. This coupling may lead to instabilities in the solution process, and you may require special solution techniques in order to obtain a converged solution. Solution techniques that may be beneficial in swirling or rotating flow calculations include the following:

- (Pressure-based segregated solver only) Use the PRESTO! scheme (enabled in the **Pressure** list for **Spatial Discretization** in the **Solution Methods Task Page** (p. 2204)), which is well-suited for the steep pressure gradients involved in swirling flows.

- Ensure that the mesh is sufficiently refined to resolve large gradients in pressure and swirl velocity.

- (Pressure-based solver only) Change the under-relaxation parameters on the velocities, perhaps to 0.3–0.5 for the radial and axial velocities and 0.8–1.0 for swirl.

- (Pressure-based solver only) Use a sequential or step-by-step solution procedure, in which some equations are temporarily left inactive (see below).

- If necessary, start the calculations using a low rotational speed or inlet swirl velocity, increasing the rotation or swirl gradually in order to reach the final desired operating condition (see below).

See **Using the Solver** (p. 1405) for details on the procedures used to make these changes to the solution parameters. More details on the step-by-step procedure and on the gradual increase of the rotational speed are provided below.

### 8.3.4.2.1. Step-By-Step Solution Procedures for Axisymmetric Swirling Flows

Often, flows with a high degree of swirl or rotation will be easier to solve if you use the following step-by-step solution procedure, in which only selected equations are left active in each step. This approach
allows you to establish the field of angular momentum, then leave it fixed while you update the velocity field, and then finally to couple the two fields by solving all equations simultaneously.

**Important**

Since the density-based solvers solve all the flow equations simultaneously, the following procedure applies only to the pressure-based solver.

In this procedure, you will use the Equations... button in the Solution Controls Task Page (p. 2208) to turn individual transport equations on and off between calculations.

1. If your problem involves inflow/outflow, begin by solving the flow without rotation or swirl effects. That is, enable the Axisymmetric option instead of the Axisymmetric Swirl option in the General Task Page (p. 1888), and do not set any rotating boundary conditions. The resulting flow-field data can be used as a starting guess for the full problem.

2. Enable the Axisymmetric Swirl option and set all rotating/swirling boundary conditions.

3. Begin the prediction of the rotating/swirling flow by solving only the momentum equation describing the circumferential velocity. This is the Swirl Velocity listed in the Equations list in the Equations Dialog Box (p. 2210). Let the rotation "diffuse" throughout the flow field, based on your boundary condition inputs. In a turbulent flow simulation, you may also want to leave the turbulence equations active during this step. This step will establish the field of rotation throughout the domain.

4. Turn off the momentum equations describing the circumferential motion (Swirl Velocity). Leaving the velocity in the circumferential direction fixed, solve the momentum and continuity (pressure) equations (Flow in the Equations list in the Equations Dialog Box (p. 2210)) in the other coordinate directions. This step will establish the axial and radial flows that are a result of the rotation in the field. Again, if your problem involves turbulent flow, you should leave the turbulence equations active during this calculation.

5. Turn on all of the equations simultaneously to obtain a fully coupled solution. Note the under-relaxation controls suggested above.

In addition to the steps above, you may want to simplify your calculation by solving isothermal flow before adding heat transfer or by solving laminar flow before adding a turbulence model. These two methods can be used for any of the solvers (that is, pressure-based or density-based).

### 8.3.4.2.2. Improving Solution Stability by Gradually Increasing the Rotational or Swirl Speed

Because the rotation or swirl defined by the boundary conditions can lead to large complex forces in the flow, your ANSYS Fluent calculations will be less stable as the speed of rotation or degree of swirl increases. Hence, one of the most effective controls you can apply to the solution is to solve your rotating flow problem starting with a low rotational speed or swirl velocity and then slowly increase the magnitude up to the desired level. The procedure for accomplishing this is as follows:

1. Set up the problem using a low rotational speed or swirl velocity in your inputs for boundary conditions. The rotation or swirl in this first attempt might be selected as 10% of the actual operating conditions.

2. Solve the problem at these conditions, perhaps using the step-by-step solution strategy outlined above.

3. Save this initial solution data.
4. Modify your inputs (boundary conditions). Increase the speed of rotation, perhaps doubling it.

5. Restart the calculation using the solution data saved in step 3 as the initial solution for the new calculation. Save the new data.

6. Continue to increment the speed of rotation, following steps 4 and 5, until you reach the desired operating condition.

**8.3.4.2.2.1. Postprocessing for Axisymmetric Swirling Flows**

Reporting of results for axisymmetric swirling flows is the same as for other flows. The following additional variables are available for postprocessing when axisymmetric swirl is active:

- Swirl Velocity (in the Velocity... category)
- Swirl-Wall Shear Stress (in the Wall Fluxes... category)

**8.4. Compressible Flows**

Compressibility effects are encountered in gas flows at high velocity and/or in which there are large pressure variations. When the flow velocity approaches or exceeds the speed of sound of the gas or when the pressure change in the system ($\Delta p/p$) is large, the variation of the gas density with pressure has a significant impact on the flow velocity, pressure, and temperature. Compressible flows create a unique set of flow physics for which you must be aware of the special input requirements and solution techniques described in this section. Figure 8.12: Transonic Flow in a Converging-Diverging Nozzle (p. 525) and Figure 8.13: Mach 0.675 Flow Over a Bump in a 2D Channel (p. 526) show examples of compressible flows computed using ANSYS Fluent.

**Figure 8.12: Transonic Flow in a Converging-Diverging Nozzle**
Compressible flows can be characterized by the value of the Mach number:
\[ M \equiv \frac{u}{c} \]  
(8.16)

Here, \( c \) is the speed of sound in the gas:
\[ c = \sqrt{\gamma RT} \]  
(8.17)

and \( \gamma \) is the ratio of specific heats \( \left( \frac{c_p}{c_v} \right) \).

When the Mach number is less than 1.0, the flow is termed subsonic. At Mach numbers much less than 1.0 (\( M \approx 1.0 \) or so), compressibility effects are negligible and the variation of the gas density with pressure can safely be ignored in your flow modeling. As the Mach number approaches 1.0 (which is referred to as the transonic flow regime), compressibility effects become important. When the Mach number exceeds 1.0, the flow is termed supersonic, and may contain shocks and expansion fans which can impact the flow pattern significantly. ANSYS Fluent provides a wide range of compressible flow modeling capabilities for subsonic, transonic, and supersonic flows.
8.4.2. Physics of Compressible Flows

Compressible flows are typically characterized by the total pressure $p_0$ and total temperature $T_0$ of the flow. For an ideal gas, these quantities can be related to the static pressure and temperature by the following:

\[
\frac{p_0}{p} = \exp\left(\frac{T_0}{R} \int_{T}^{T_0} \frac{C_P}{T} \, dT\right)
\]  

(8.18)

For constant $C_P$, Equation 8.18 (p. 527) reduces to

\[
\frac{p_0}{p} = \left(1 + \frac{\gamma - 1}{2} M^2\right)^{\gamma/(\gamma - 1)}
\]

\[
\frac{T_0}{T} = 1 + \frac{\gamma - 1}{2} M^2
\]

These relationships describe the variation of the static pressure and temperature in the flow as the velocity (Mach number) changes under isentropic conditions. For example, given a pressure ratio from inlet to exit (total to static), Equation 8.19 (p. 527) can be used to estimate the exit Mach number that would exist in a one-dimensional isentropic flow. For air, Equation 8.19 (p. 527) $p/p_0$ of 0.5283. This choked flow condition will be established at the point of minimum flow area (for example, in the throat of a nozzle). In the subsequent area expansion the flow may either accelerate to a supersonic flow in which the pressure will continue to drop, or return to subsonic flow conditions, decelerating with a pressure rise. If a supersonic flow is exposed to an imposed pressure increase, a shock will occur, with a sudden pressure rise and deceleration accomplished across the shock.

8.4.2.1. Basic Equations for Compressible Flows

Compressible flows are described by the standard continuity and momentum equations solved by ANSYS Fluent, and you do not need to activate any special physical models (other than the compressible treatment of density as detailed below). The energy equation solved by ANSYS Fluent correctly incorporates the coupling between the flow velocity and the static temperature, and should be activated whenever you are solving a compressible flow. In addition, if you are using the pressure-based solver, you should activate the viscous dissipation terms in Equation 5.1 in the Theory Guide, which become important in high-Mach-number flows.

8.4.2.2. The Compressible Form of the Gas Law

For compressible flows, the ideal gas law is written in the following form:

\[
\rho = \frac{p_{op} + p}{R \frac{T}{M_w}}
\]

(8.20)
where $p_{op}$ is the operating pressure defined in the Operating Conditions Dialog Box (p. 2095), $p$ is the local static pressure relative to the operating pressure, $R$ is the universal gas constant, and $M_w$ is the molecular weight. The temperature, $T$, will be computed from the energy equation.

Some compressible flow problems involve fluids that do not behave as ideal gases. For example, flow under very high-pressure conditions cannot typically be modeled accurately using the ideal-gas assumption. Therefore, the real gas model described in Real Gas Models (p. 468) should be used instead.

### 8.4.3. Modeling Inputs for Compressible Flows

To set up a compressible flow in ANSYS Fluent, you must follow the steps listed below. (Only those steps relevant specifically to the setup of compressible flows are listed here. You must set up the rest of the problem as usual.)

1. Set the **Operating Pressure** in the Operating Conditions Dialog Box (p. 2095).
   
   ![Boundary Conditions → Operating Conditions...](You can think of $p_{op}$ as the absolute static pressure at a point in the flow where you will define the gauge pressure $p$ to be zero. See Operating Pressure (p. 466) for guidelines on setting the operating pressure. For time-dependent compressible flows, you may want to specify a floating operating pressure instead of a constant operating pressure. See Floating Operating Pressure (p. 529) for details.)

2. Activate solution of the energy equation in the Energy Dialog Box (p. 1903).

   ![Models → Energy → Edit...](3. (Pressure-based solver only) If you are modeling turbulent flow, activate the optional viscous dissipation terms in the energy equation by turning on Viscous Heating in the Viscous Model Dialog Box (p. 1903). Note that these terms can be important in high-speed flows.

   ![Models → Viscous → Edit...](This step is not necessary if you are using one of the density-based solvers, because the density-based solvers always include the viscous dissipation terms in the energy equation.)

3. Set the following items in the Create/Edit Materials Dialog Box (p. 2022):
   
   ![Materials → Create/Edit...](a. Select **ideal-gas** in the drop-down list next to **Density**.
   
   b. Define all relevant properties (specific heat, molecular weight, thermal conductivity, etc.).

4. Set cell zone conditions and boundary conditions (using the Boundary Conditions Task Page (p. 2102) and Cell Zone Conditions Task Page (p. 2083)), being sure to choose a well-posed cell zone or boundary condition combination that is appropriate for the flow regime. See below for details. Recall that all inputs for pressure (either total pressure or static pressure) must be relative to the operating pressure, and the temperature inputs at inlets should be total (stagnation) temperatures, not static temperatures.
Boundary Conditions

These inputs should ensure a well-posed compressible flow problem. You will also want to consider special solution parameter settings, as noted in Solution Strategies for Compressible Flows (p. 531), before beginning the flow calculation.

8.4.3.1. Boundary Conditions for Compressible Flows

Well-posed inlet and exit boundary conditions for compressible flow are listed below:

- For flow inlets:
  - Pressure inlet: Inlet total temperature and total pressure and, for supersonic inlets, static pressure
  - Mass flow inlet: Inlet mass flow and total temperature

- For flow exits:
  - Pressure outlet: Exit static pressure (ignored if flow is supersonic at the exit. All the information travels downstream in a supersonic region, hence the pressure at the outlet can be computed by directly extrapolating from the adjacent cell center (p. 2558). Therefore, it is not meaningful to use the exit static pressure prescribed in the boundary conditions task page, and the exit static pressure is ignored).

It is important to note that your boundary condition inputs for pressure (either total pressure or static pressure) must be in terms of gauge pressure — that is, pressure relative to the operating pressure defined in the Operating Conditions Dialog Box (p. 2095), as described above.

All temperature inputs at inlets should be total (stagnation) temperatures, not static temperatures.

8.4.4. Floating Operating Pressure

ANSYS Fluent provides a “floating operating pressure” option to handle time-dependent compressible flows with a gradual increase in the absolute pressure in the domain. This option is desirable for slow subsonic flows with static pressure build-up, since it efficiently accounts for the slow changing of absolute pressure without using acoustic waves as the transport mechanism for the pressure build-up.

Examples of typical applications include the following:

- combustion or heating of a gas in a closed domain
- pumping of a gas into a closed domain

8.4.4.1. Limitations

The floating operating pressure option should not be used for transonic or incompressible flows. In addition, it cannot be used if your model includes any pressure inlet, pressure outlet, exhaust fan, inlet vent, intake fan, outlet vent, or pressure far field boundaries.

8.4.4.2. Theory

The floating operating pressure option allows ANSYS Fluent to calculate the pressure rise (or drop) from the integral mass balance, separately from the solution of the pressure correction equation. When this option is activated, the absolute pressure at each iteration can be expressed as
\[ p_{\text{abs}} = p_{\text{op, float}} + p \]  

(8.21)

where \( p \) is the pressure relative to the reference location, which in this case is in the cell with the minimum pressure value. Therefore the reference location itself is floating.

\( p_{\text{op, float}} \) is referred to as the floating operating pressure, and is defined as

\[ p_{\text{op, float}} = p_{\text{op}} + \Delta p_{\text{op}} \]  

(8.22)

where \( p_{\text{op}} \) is the initial operating pressure and \( \Delta p_{\text{op}} \) is the pressure rise.

Including the pressure rise \( \Delta p_{\text{op}} \) in the floating operating pressure \( p_{\text{op, float}} \) rather than in the pressure \( p \), helps to prevent roundoff error. If the pressure rise were included in \( p \), the calculation of the pressure gradient for the momentum equation would give an inexact balance due to precision limits for 32-bit real numbers.

### 8.4.4.3. Enabling Floating Operating Pressure

When time dependence is active, you can turn on the **Floating Operating Pressure** option in the **Operating Conditions Dialog Box** (p. 2095).

![Boundary Conditions → Operating Conditions...](Note that the inputs for Reference Pressure Location will disappear when you enable Floating Operating Pressure, since these inputs are no longer relevant.)

---

**Important**

The floating operating pressure option should *not* be used for transonic flows or for incompressible flows. It is meaningful only for slow subsonic flows of ideal gases, when the characteristic time scale is much larger than the sonic time scale.

---

### 8.4.4.4. Setting the Initial Value for the Floating Operating Pressure

When the floating operating pressure option is enabled, you must specify a value for the **Initial Operating Pressure** in the **Solution Initialization Task Page** (p. 2249).

![Solution Initialization](This initial value is stored in the case file with all your other initial values.)

---

### 8.4.4.5. Storage and Reporting of the Floating Operating Pressure

The current value of the floating operating pressure is stored in the data file. If you visit the **Operating Conditions Dialog Box** (p. 2095) after a number of time steps have been performed, the current value of the **Operating Pressure** will be displayed.

Note that the floating operating pressure will automatically be reset to the initial operating pressure if you reset the data (that is, start over at the first iteration of the first time step).
8.4.4.6. Monitoring Absolute Pressure

You can monitor the absolute pressure during the calculation using the Surface Monitor Dialog Box (p. 2233) (see Monitoring Surface Integrals (p. 1493) for details). You can also generate graphical plots or alphanumeric reports of absolute pressure when your solution is complete. The Absolute Pressure variable is contained in the Pressure... category of the variable selection drop-down list that appears in postprocessing dialog boxes. See Field Function Definitions (p. 1765) for its definition.

8.4.5. Solution Strategies for Compressible Flows

The difficulties associated with solving compressible flows are a result of the high degree of coupling between the flow velocity, density, pressure, and energy. This coupling may lead to instabilities in the solution process and, therefore, may require special solution techniques in order to obtain a converged solution. In addition, the presence of shocks (discontinuities) in the flow introduces an additional stability problem during the calculation. Solution techniques that may be beneficial in compressible flow calculations include the following:

• (Pressure-based solver only) Initialize the flow to be near stagnation (that is velocity small but not zero, pressure to inlet total pressure, temperature to inlet total temperature). Turn off the energy equation for the first 50 iterations. Leave the energy under-relaxation at 1. Set the pressure under-relaxation to 0.4, and the momentum under-relaxation to 0.3. After the solution stabilizes and the energy equation has been turned on, increase the pressure under-relaxation to 0.7.

• Set reasonable limits for the temperature and pressure (in the Solution Limits Dialog Box (p. 2211)) to avoid solution divergence, especially at the start of the calculation. If ANSYS Fluent prints messages about temperature or pressure being limited as the solution nears convergence, the high or low computed values may be physical, and you must change the limits to allow these values.

• If required, begin the calculations using a reduced pressure ratio at the boundaries, increasing the pressure ratio gradually in order to reach the final desired operating condition. If the Mach number is low, you can also consider starting the compressible flow calculation from an incompressible flow solution (although the incompressible flow solution can in some cases be a rather poor initial guess for the compressible calculation).

• In some cases, computing an inviscid solution as a starting point may be helpful.

See Using the Solver (p. 1405) for details on the procedures used to make these changes to the solution parameters.

8.4.6. Reporting of Results for Compressible Flows

You can display the results of your compressible flow calculations in the same manner that you would use for an incompressible flow. The variables listed below are of particular interest when you model compressible flow:

• Total Temperature

• Total Pressure

• Mach Number

These variables are contained in the variable selection drop-down list that appears in postprocessing dialog boxes. Total Temperature is in the Temperature... category, Total Pressure is in the Pressure...
category, and Mach Number is in the Velocity... category. See Field Function Definitions (p. 1765) for their definitions.

8.5. Inviscid Flows

Inviscid flow analysis neglect the effect of viscosity on the flow and are appropriate for high-Reynolds-number applications where inertial forces tend to dominate viscous forces. One example for which an inviscid flow calculation is appropriate is an aerodynamic analysis of some high-speed projectile. In a case like this, the pressure forces on the body will dominate the viscous forces. Hence, an inviscid analysis will give you a quick estimate of the primary forces acting on the body. After the body shape has been modified to maximize the lift forces and minimize the drag forces, you can perform a viscous analysis to include the effects of the fluid viscosity and turbulent viscosity on the lift and drag forces.

Another area where inviscid flow analysis are routinely used is to provide a good initial solution for problems involving complicated flow physics and/or complicated flow geometry. In a case like this, the viscous forces are important, but in the early stages of the calculation the viscous terms in the momentum equations will be ignored. Once the calculation has been started and the residuals are decreasing, you can turn on the viscous terms (by enabling laminar or turbulent flow) and continue the solution to convergence. For some very complicated flows, this is the only way to get the calculation started.

Information about inviscid flows is provided in the following subsections:

8.5.1. Setting Up an Inviscid Flow Model
8.5.2. Solution Strategies for Inviscid Flows
8.5.3. Postprocessing for Inviscid Flows

For more information about the theoretical background of inviscid flows, see Inviscid Flows in the Theory Guide.

8.5.1. Setting Up an Inviscid Flow Model

For inviscid flow problems, you must perform the following steps during the problem setup procedure. (Only those steps relevant specifically to the setup of inviscid flow are listed here. You must set up the rest of the problem as usual.)

1. Activate the calculation of inviscid flow by selecting Inviscid in the Viscous Model Dialog Box (p. 1903).

2. Set boundary conditions and flow properties.

3. Solve the problem and examine the results.
8.5.2. Solution Strategies for Inviscid Flows

Since inviscid flow problems will usually involve high-speed flow, you may have to reduce the under-relaxation factors for momentum (if you are using the pressure-based solver) or reduce the Courant number (if you are using the density-based solver), in order to get the solution started. Once the flow is started and the residuals are monotonically decreasing, you can start increasing the under-relaxation factors or Courant number back up to the default values.

Modifications to the under-relaxation factors and the Courant number can be made in the Solution Controls Task Page (p. 2208).

Solution Controls

The solution strategies for compressible flows apply also to inviscid flows. See Solution Strategies for Compressible Flows (p. 531) for details.

8.5.3. Postprocessing for Inviscid Flows

If you are interested in the lift and drag forces acting on your model, you can use the Force Reports Dialog Box (p. 2353) to compute them.

Reports → Forces → Set Up...

See Forces on Boundaries (p. 1751) for details.
Chapter 9: Modeling Flows with Moving Reference Frames

This chapter provides details about the moving reference frame capabilities in ANSYS Fluent.

The information in this chapter is divided into the following sections:

9.1. Introduction
9.2. Flow in Single Moving Reference Frames (SRF)
9.3. Flow in Multiple Moving Reference Frames

9.1. Introduction

ANSYS Fluent solves the equations of fluid flow and heat transfer, by default, in a stationary (or inertial) reference frame. However, there are many problems where it is advantageous to solve the equations in a moving (or non-inertial) reference frame. Such problems typically involve moving parts (such as rotating blades, impellers, and similar types of moving surfaces), and it is the flow around these moving parts that is of interest. In most cases, the moving parts render the problem unsteady when viewed from the stationary frame. With a moving reference frame, however, the flow around the moving part can (with certain restrictions) be modeled as a steady-state problem with respect to the moving frame.

ANSYS Fluent's moving reference frame modeling capability allows you to model problems involving moving parts by allowing you to activate moving reference frames in selected cell zones. When a moving reference frame is activated, the equations of motion are modified to incorporate the additional acceleration terms that occur due to the transformation from the stationary to the moving reference frame. By solving these equations in a steady-state manner, the flow around the moving parts can be modeled.

For many problems, it may be possible to refer the entire computational domain to a single moving reference frame. This is known as the single reference frame (or SRF) approach. The use of the SRF approach is possible; provided the geometry meets certain requirements. For more complex geometries, it may not be possible to use a single reference frame. In such cases, you must break up the problem into multiple cell zones, with well-defined interfaces between the zones. The manner in which the interfaces are treated leads to two approximate, steady-state modeling methods for this class of problem: the multiple reference frame (or MRF) approach, and the mixing plane approach. These approaches will be discussed in The Multiple Reference Frame Model (p. 545) and The Mixing Plane Model (p. 547). If unsteady interaction between the stationary and moving parts is important, you can employ the sliding mesh approach to capture the transient behavior of the flow. The sliding meshing model will be discussed in Modeling Flows Using Sliding and Dynamic Meshes (p. 559).

The principal reason for employing a moving reference frame is to render a problem that is unsteady in the stationary (inertial) frame, steady with respect to the moving frame. For a steadily moving frame (for example, the frame speed is constant), it is possible to transform the equations of fluid motion to the moving frame such that steady-state solutions are possible. By default, ANSYS Fluent permits the activation of a moving reference frame with a steady speed. If the speed is not constant, the transformed equations will contain additional terms (see Relative Velocity Formulation in the Theory Guide). It should also be noted that you can run an unsteady simulation in a moving reference frame with constant speed. This would be necessary if you wanted to simulate, for example, vortex shedding from a rotating...
fan blade. The unsteadiness in this case is due to a natural fluid instability (vortex generation) rather than induced from interaction with a stationary component.

For more information about the equations for moving reference frames, see Equations for a Moving Reference Frame in the Theory Guide.

Figure 9.1: Single Component (Blower Wheel Blade Passage)
9.2. Flow in Single Moving Reference Frames (SRF)

Many problems permit the entire computational domain to be referred to a single moving reference frame (hence the name SRF modeling). In such cases, the equations given in Equations for a Moving Reference Frame are solved in all fluid cell zones. Steady-state solutions are possible in SRF models provided suitable boundary conditions are prescribed. In particular, wall boundaries must adhere to the following requirements:

- Any walls that are moving with the reference frame can assume any shape. An example would be the blade surfaces associated with a pump impeller. The no slip condition is defined in the relative frame such that the relative velocity is zero on the moving walls.

- For a rotating problem, you can define walls that are non-moving with respect to the stationary coordinate system, but these walls must be surfaces of revolution about the axis of rotation. Here the no slip condition is defined such that the absolute velocity is zero on the walls. An example of this type of boundary would be a cylindrical wind tunnel wall that surrounds a rotating propeller.

Rotationally periodic boundaries may also be used, but the surface must be periodic about the axis of rotation. As an example, it is very common to model flow through a blade row of a turbomachine by assuming the flow to be rotationally periodic and using a periodic domain about a single blade. This permits good resolution of the flow around the blade without the expense of modeling all blades in the blade row (see Figure 9.3: Single Blade Model with Rotationally Periodic Boundaries (p. 538)).

Flow boundary conditions in ANSYS Fluent (inlets and outlets) can, in most cases, be prescribed in either the stationary or moving frames. For example, for a velocity inlet, one can specify either the relative velocity or absolute velocity, depending on which is more convenient. For additional information on these and other boundary conditions, see Setting Up a Single Moving Reference Frame Problem (p. 538) and Cell Zone and Boundary Conditions (p. 201).
9.2.1. Mesh Setup for a Single Moving Reference Frame

It is important to remember the following coordinate-system constraints when you are setting up a problem involving a moving reference frame for a rotating problem:

- For 2D problems, the axis of rotation must be parallel to the $z$ axis.
- For 2D axisymmetric problems, the axis of rotation must be the $x$ axis.
- For 3D geometries, you should generate the mesh with a specific origin and rotational axis in mind for the rotating cell zone. Usually it is convenient to use the origin of the global coordinate system $(0,0,0)$ for the frame origin, and either the $x$, $y$, or $z$ axis for the rotational axis; however, ANSYS Fluent can accommodate an arbitrary origin and rotational axis.

With 3D rotating problems, it is also important to note that if you want to include walls that have zero velocity in the stationary frame, these walls must be a surface of revolution with respect to the axis of rotation. If the stationary walls are not surfaces of revolution, you must encapsulate the rotating parts with interface boundaries, thereby breaking your model up into multiple zones, and use either the MRF or mixing plane models for steady state solutions (see The Multiple Reference Frame Model (p. 545) and The Mixing Plane Model (p. 547)), or the sliding mesh model for unsteady interaction (see Modeling Flows Using Sliding and Dynamic Meshes (p. 559)).

9.2.2. Setting Up a Single Moving Reference Frame Problem

To model a problem involving a single moving reference frame, follow the steps outlined below.

1. Select the Velocity Formulation to be used when solving: either Relative or Absolute. (See Choosing the Relative or Absolute Velocity Formulation (p. 541) for details.)

   **General**

   (Note that this step is irrelevant if you are using one of the density-based solvers; these solvers always use an absolute velocity formulation.)
2. For each cell zone in the domain, specify the translational velocity of the reference frame and/or the angular velocity ($\omega$) of the reference frame and the axis about which it rotates.

**Cell Zone Conditions**

a. In the **Fluid** or **Solid** dialog box, specify the **Rotation-Axis Origin** and **Rotation-Axis Direction** for the frame motion to define the axis of rotation.

b. Also in the **Fluid** (Figure 9.4: The Fluid Dialog Box Displaying Frame Motion Inputs (p. 540)) or **Solid** dialog box, enable the **Frame Motion** option and then set the **Speed** under **Rotational Velocity** and/or the **X**, **Y**, and **Z** components of the **Translational Velocity** in the expanded portion of the dialog box under the **Reference Frame** tab. Note that the speed can be specified as a constant value or a transient profile. The transient profile may be in a file format, as described in Defining Transient Cell Zone and Boundary Conditions (p. 388), or a UDF macro, described in DEFINE_TRANSIENT_PROFILE. Specifying the individual velocities as either a profile or a UDF allows you to specify a specific input of the frame motion individually. However, you can also specify the frame motion inputs via a single user-defined function that uses the UDF macro DEFINE_ZONE_MOTION. This may prove to be quite convenient if you are modeling a more complicated motion of the moving reference frame, where the hooking of many different user-defined functions or profiles can be cumbersome.

**Note**

If you decide to hook a UDF, you will no longer have access to the rotation axis origin and direction, or the velocities.

Details about these inputs are presented in **Inputs for Fluid Zones** (p. 216) and in **Inputs for Solid Zones** (p. 221). Details about the zone motion UDF can be found in DEFINE_ZONE_MOTION in the UDF Manual.

c. If you need to switch between the moving reference frame and moving mesh models, simply click the **Copy To Mesh Motion** for zones with a moving frame of reference and **Copy to Frame Motion** for zones with moving meshes to transfer motion variables, such as the axes, frame origin, and velocity components between the two models. The variables used for the origin, axis, and velocity components, as well as for the UDF DEFINE_ZONE_MOTION will be copied. This is particularly useful if you are doing a steady-state MRF simulation to obtain an initial solution for a transient Moving Mesh simulation in a turbomachine.
Important

For solid zones, you only need to activate the Frame Motion option if you intend to include the convective terms in the energy equation for the solid (Equation 5.11 in the Theory Guide). Normally, this is not required if you want to do a conjugate heat transfer problem where the solid and fluid zones are moving together.

3. Define the velocity boundary conditions at walls. You can choose to define either an absolute velocity or a velocity relative to the moving reference frame (that is, relative to the velocity of the adjacent cell zone specified in step 2).
If the wall is moving at the speed of the moving frame (and hence stationary in the moving frame), it is convenient to specify a relative angular velocity of zero. Likewise, a wall that is stationary in the non-moving frame of reference should be given a velocity of zero in the absolute reference frame. Specifying the wall velocities in this manner obviates the need to modify these inputs later if a change is made in the velocity of the fluid zone.

Details about these inputs are presented in Velocity Conditions for Moving Walls (p. 311).

4. Define the boundary conditions at the inlets, as described in Boundary Conditions (p. 255). For velocity inlets, you can choose to define either absolute velocities or velocities relative to the motion of the adjacent cell zone (specified in step 2). Likewise, the total pressure and flow direction can be prescribed in absolute or relative frames for pressure inlets.

Details about these inputs are presented in Defining the Flow Direction (p. 265) and Defining the Velocity (p. 272).

9.2.2.1. Choosing the Relative or Absolute Velocity Formulation

It is recommended that you use the velocity formulation that will result in most of the flow domain having the smallest velocities in that frame, thereby reducing the numerical diffusion in the solution and leading to a more accurate solution.

The absolute velocity formulation is preferred in applications where the flow in most of the domain is not moving (for example, a fan in a large room). The relative velocity formulation is appropriate when most of the fluid in the domain is moving, as in the case of a large impeller in a mixing tank.

9.2.2.1.1. Example

A problem with stationary outer walls and a rotating impeller can be solved in a single reference frame. The example is illustrated in Figure 9.5: Geometry with the Rotating Impeller (p. 541).

Figure 9.5: Geometry with the Rotating Impeller

In case A, it is expected that only the flow near the impeller would be rotating and that much of the flow away from the impeller would have a low velocity magnitude in the absolute frame. Therefore, solving using the absolute velocity formulation is recommended. In case B, most of the flow is expected
to be rotating with a velocity close to that of the impeller. Hence, the relative velocity formulation is appropriate.

In a situation between case A and case B, either of the formulations may be used.

**Important**

- If the velocity formulation is switched during the solution process, ANSYS Fluent will not transform the current solution to the other frame, which can lead to large jumps in residuals. If changing the frame is necessary, it is recommended that you first reinitialize, and then solve.

- When one of the density-based solution algorithms is used, the absolute formulation is always used; the relative velocity formulation is not available in the density-based solvers.

For velocity inlets, pressure inlets, mass flow inlets, and walls, you may specify velocity in either the absolute or the relative frame, regardless of whether the absolute or relative velocity formulation is used in the computation.

For pressure outlets, the specified static pressure is independent of frame. However, when there is backflow at a pressure outlet, the specified static pressure is used as the total pressure. For calculations using the absolute velocity formulation, the specified static pressure is used as the total pressure in the absolute frame; for the relative velocity formulation, the specified static pressure is assumed to be the total pressure in the relative frame. As for the flow direction, ANSYS Fluent assumes the absolute velocity to be normal to the pressure outlet for the absolute velocity formulation; for the relative velocity formulation, it is the relative velocity that is assumed to be normal to the pressure outlet.

### 9.2.3. Solution Strategies for a Single Moving Reference Frame

The difficulties associated with solving flows in moving reference frames are similar to those discussed in Solution Strategies for Axisymmetric Swirling Flows (p. 523). The primary issue you must confront is the high degree of coupling between the momentum equations when the influence of the rotational terms is large. A high degree of rotation introduces a large radial pressure gradient that drives the flow in the axial and radial directions, thereby setting up a distribution of the swirl or rotation in the field. This coupling may lead to instabilities in the solution process, and hence require special solution techniques to obtain a converged solution. Some techniques that may be beneficial include the following:

- (Pressure-based solver only) Consider switching the frame in which velocities are solved by changing the velocity formulation setting in the General Task Page (p. 1888). (See Choosing the Relative or Absolute Velocity Formulation (p. 541) for details.)

- (Pressure-based segregated solver only) Use the PRESTO! scheme (enabled in the Solution Methods Task Page (p. 2204)), which is well-suited for the steep pressure gradients involved in rotating flows.

- Ensure that the mesh is sufficiently refined to resolve large gradients in pressure and swirl velocity.

- (Pressure-based, segregated solver only) Reduce the under-relaxation factors for the velocities, perhaps to 0.3–0.5 or lower, if necessary.

- Begin the calculations using a low rotational speed, increasing the rotational speed gradually in order to reach the final desired operating condition.
See Using the Solver (p. 1405) for details on the procedures used to make these changes to the solution parameters.

### 9.2.3.1. Gradual Increase of the Rotational Speed to Improve Solution Stability

Because the rotation of the reference frame and the rotation defined via boundary conditions can lead to large complex forces in the flow, your ANSYS Fluent calculations may be less stable as the speed of rotation (and hence the magnitude of these forces) increases. One of the most effective controls you can exert on the solution is to start with a low rotational speed and then slowly increase the rotation up to the desired level. The procedure you use to accomplish this is as follows:

1. Set up the problem using a low rotational speed in your inputs for boundary conditions and for the angular velocity of the reference frame. The rotational speed in this first attempt might be selected as 10% of the actual operating condition.

2. Solve the problem at these conditions.

3. Save this initial solution data.

4. Modify your inputs (that is, boundary conditions and angular velocity of the reference frame). Increase the speed of rotation, perhaps doubling it.

5. Restart or continue the calculation using the solution data saved in Step 3 as the initial guess for the new calculation. Save the new data.

6. Continue to increment the rotational speed, following Steps 4 and 5, until you reach the desired operating condition.

### 9.2.4. Postprocessing for a Single Moving Reference Frame

When you solve a problem in a moving reference frame, you can plot or report both absolute and relative velocities. For all velocity parameters (for example, Velocity Magnitude and Mach Number), corresponding relative values will be available for postprocessing (for example, Relative Velocity Magnitude and Relative Mach Number). These variables are contained in the Velocity... category of the variable selection drop-down list that appears in postprocessing dialog boxes. Relative values are also available for postprocessing of total pressure, total temperature, and any other parameters that include a dynamic contribution dependent on the reference frame (for example, Relative Total Pressure, Relative Total Temperature, Rothalpy).

When plotting velocity vectors, you can choose to plot vectors in the absolute frame (the default), or you can select Relative Velocity in the Vectors of drop-down list in the Vectors Dialog Box (p. 2286) to plot vectors in the moving frame. If you plot relative velocity vectors, you might want to color the vectors by relative velocity magnitude (by choosing Relative Velocity Magnitude in the Color by list); by default they will be colored by absolute velocity magnitude. Figure 9.6: Absolute Velocity Vectors (p. 544) and Figure 9.7: Relative Velocity Vectors (p. 544) show absolute and relative velocity vectors in a moving domain with a stationary outer wall.
9.3. Flow in Multiple Moving Reference Frames

Many problems involve multiple moving parts or contain stationary surfaces which are not surfaces of revolution (and therefore cannot be used with the Single Reference Frame modeling approach). For these problems, you must break up the model into multiple fluid/solid cell zones, with interface boundaries separating the zones. Zones that contain the moving components can then be solved using the moving reference frame equations (Equations for a Moving Reference Frame in the Theory Guide), whereas stationary zones can be solved with the stationary frame equations. The manner in which the equations are treated at the interface lead to two approaches that are supported in ANSYS Fluent:
• Multiple Moving Reference Frames
  – Multiple Reference Frame Model (MRF)
  – Mixing Plane Model (MPM)
• Sliding Mesh Model (SMM)

Both the MRF and mixing plane approaches are steady-state approximations, and differ primarily in the manner in which conditions at the interfaces are treated. These approaches will be discussed in the sections below. The sliding mesh model approach is, on the other hand, inherently unsteady due to the motion of the mesh with time. This approach is discussed in Modeling Flows Using Sliding and Dynamic Meshes (p. 559).

For additional information, see the following sections:
  9.3.1. The Multiple Reference Frame Model
  9.3.2. The Mixing Plane Model
  9.3.3. Mesh Setup for a Multiple Moving Reference Frame
  9.3.4. Setting Up a Multiple Moving Reference Frame Problem
  9.3.5. Solution Strategies for MRF and Mixing Plane Problems
  9.3.6. Postprocessing for MRF and Mixing Plane Problems

9.3.1. The Multiple Reference Frame Model

Additional information about the MRF model is presented in the following sections:
  9.3.1.1. Overview
  9.3.1.2. Limitations

9.3.1.1. Overview

The MRF model [53] (p. 2559) is, perhaps, the simplest of the two approaches for multiple zones. It is a steady-state approximation in which individual cell zones can be assigned different rotational and/or translational speeds. The flow in each moving cell zone is solved using the moving reference frame equations (see Introduction (p. 535)). If the zone is stationary ($\omega = 0$), the equations reduce to their stationary forms. At the interfaces between cell zones, a local reference frame transformation is performed to enable flow variables in one zone to be used to calculate fluxes at the boundary of the adjacent zone. For more information about the MRF interface formulation, see The MRF Interface Formulation in the Theory Guide.

It should be noted that the MRF approach does not account for the relative motion of a moving zone with respect to adjacent zones (which may be moving or stationary); the mesh remains fixed for the computation. This is analogous to freezing the motion of the moving part in a specific position and observing the instantaneous flowfield with the rotor in that position. Hence, the MRF is often referred to as the “frozen rotor approach.”

While the MRF approach is clearly an approximation, it can provide a reasonable model of the flow for many applications. For example, the MRF model can be used for turbomachinery applications in which rotor-stator interaction is relatively weak, and the flow is relatively uncomplicated at the interface between the moving and stationary zones. In mixing tanks, for example, since the impeller-baffle interactions are relatively weak, large-scale transient effects are not present and the MRF model can be used.

Another potential use of the MRF model is to compute a flow field that can be used as an initial condition for a transient sliding mesh calculation. This eliminates the need for a startup calculation. The multiple reference frame model should not be used, however, if it is necessary to actually simulate the transients.
that may occur in strong rotor-stator interactions, the sliding mesh model alone should be used (see Modeling Flows Using Sliding and Dynamic Meshes (p. 559).

For more information about and examples of multiple moving reference frames, see The Multiple Reference Frame Model in the Theory Guide.

**9.3.1.2. Limitations**

The following limitations exist when using the MRF approach:

- The interfaces separating a moving region from adjacent regions must be oriented such that the component of the frame velocity normal to the boundary is zero. This means that for a translationally moving frame, the moving zone's boundaries must be parallel to the translational velocity vector. For rotating problems, the interfaces must be surfaces of revolution about the axis of rotation defined for the fluid zone. For the example shown Figure 2.4: Geometry with One Rotating Impeller (in the Theory Guide), this requires the dashed boundary to be circular (not square or any other shape).

- Strictly speaking, the use of multiple reference frames is meaningful only for steady flow. However, ANSYS Fluent will allow you to solve an unsteady flow when multiple reference frames are being used. In this case, unsteady terms (as described in Temporal Discretization in the Theory Guide) are added to all the governing transport equations. You should carefully consider whether this will yield meaningful results for your application, because, for unsteady flows, a sliding mesh calculation will generally yield more meaningful results than an MRF calculation.

- Particle trajectories and pathlines drawn by ANSYS Fluent use the velocity relative to the cell zone motion. For massless particles, the resulting pathlines follow the streamlines based on relative velocity. For particles with mass, however, the particle tracks displayed are meaningless. Similarly, coupled discrete-phase calculations are meaningless.

An alternative approach for particle tracking and coupled discrete-phase calculations with multiple reference frames is to track particles based on absolute velocity instead of relative velocity. To make this change, use the define/models/dpm/options/track-in-absolute-frame text command. Note, that the results may strongly depend on the location of walls inside the multiple reference frame. The particle injection velocities (specified in the Set Injection Properties Dialog Box (p. 2436)) are defined relative to the frame of reference in which the particles are tracked. By default, the injection velocities are specified relative to the local reference frame. If you enable the track-in-absolute-frame option, the injection velocities are specified relative to the absolute frame.

- You cannot accurately model axisymmetric swirl in the presence of multiple reference frames using the relative velocity formulation. This is because the current implementation does not apply the transformation used in Equation 2.16 (in the Theory Guide) to the swirl velocity derivatives. For this situation, the absolute velocity formulation should be used.

- Translational and rotational velocities are assumed to be constant (time varying \( \omega, v_f \) are not allowed).

- The relative velocity formulation cannot be used in combination with the MRF and mixture models. (For details, see Mixture Model Theory in the Theory Guide). For such cases, use the absolute velocity formulation instead.

- You must not have a single interface between reference frames where part of the interface is made up of a coupled two-sided wall, while another part is not coupled (that is, the normal interface treatment). In such cases, you must break the interface up into two interfaces: one that is a coupled interface, and
the other that is a standard fluid-fluid interface. See Using a Non-Conformal Mesh in ANSYS Fluent (p. 159) for the steps involved in setting up a coupled interface.

**Important**

You can switch from the MRF model to the sliding mesh model for a more robust and accurate solution, by using the `mesh/modify-zones/mrf-to-sliding-mesh` text command. See Using Sliding Meshes (p. 565) for details on how to make this change in the fluid’s boundary conditions. Currently, this switch is not possible when running in parallel or for non-conformal interfaces.

### 9.3.2. The Mixing Plane Model

The mixing plane model in ANSYS Fluent provides an alternative to the multiple reference frame and sliding mesh models for simulating flow through domains with one or more regions in relative motion.

Additional information about the mixing plane model is presented in the following sections:

- 9.3.2.1. Overview
- 9.3.2.2. Limitations

#### 9.3.2.1. Overview

As discussed in The Multiple Reference Frame Model (p. 545), the MRF model is applicable when the flow at the interface between adjacent moving/stationary zones is nearly uniform (“mixed out”). If the flow at this interface is not uniform, the MRF model may not provide a physically meaningful solution. The sliding mesh model (see Modeling Flows Using Sliding and Dynamic Meshes (p. 559)) may be appropriate for such cases, but in many situations it is not practical to employ a sliding mesh. For example, in a multistage turbomachine, if the number of blades is different for each blade row, a large number of blade passages is required in order to maintain circumferential periodicity. Moreover, sliding mesh calculations are necessarily unsteady, and therefore require significantly more computation to achieve a final, time-periodic solution. For situations where using the sliding mesh model is not feasible, the mixing plane model can be a cost-effective alternative.

In the mixing plane approach, each fluid zone is treated as a steady-state problem. Flow-field data from adjacent zones are passed as boundary conditions that are spatially averaged or “mixed” at the mixing plane interface. This mixing removes any unsteadiness that would arise due to circumferential variations in the passage-to-passage flow field (for example, wakes, shock waves, separated flow), therefore yielding a steady-state result. Despite the simplifications inherent in the mixing plane model, the resulting solutions can provide reasonable approximations of the time-averaged flow field.

#### 9.3.2.2. Limitations

Note the following limitations of the mixing plane model:

- The LES turbulence model cannot be used with the mixing plane model.
- The models for species transport and combustion cannot be used with the mixing plane model.
- The VOF multiphase model cannot be used with the mixing plane model.
- The discrete phase model cannot be used with the mixing plane model for coupled flows. Non-coupled computations can be done, but you should note that the particles leave the domain of the mixing plane.
You can find more information about the following topics in the Theory Guide:

Rotor and Stator Domains
The Mixing Plane Concept
Choosing an Averaging Method
Mixing Plane Algorithm of ANSYS Fluent
Mass Conservation
Swirl Conservation
Total Enthalpy Conservation

9.3.3. Mesh Setup for a Multiple Moving Reference Frame

Two mesh setup methods are available. Choose the method that is appropriate for your model, noting the restrictions in Limitations (p. 546).

• If the boundary between two zones that are in different reference frames is conformal (that is, the mesh node locations are identical at the boundary where the two zones meet), you can simply create the mesh as usual, with all cell zones contained in the same mesh file. A different cell zone should exist for each portion of the domain that is modeled in a different reference frame. Use an interior zone for the boundary between reference frames.

• If the boundary between two zones that are in different reference frames is non-conformal (that is, the mesh node locations are not identical at the boundary where the two zones meet), follow the non-conformal mesh setup procedure described in Using a Non-Conformal Mesh in ANSYS Fluent (p. 159).

9.3.4. Setting Up a Multiple Moving Reference Frame Problem

To learn more about setting up a multiple reference frame problem, see the following sections:
9.3.4.1. Setting Up Multiple Reference Frames
9.3.4.2. Setting Up the Mixing Plane Model

9.3.4.1. Setting Up Multiple Reference Frames

To model a problem involving multiple reference frames, perform the following:

Important

The mesh-setup constraints for a moving reference frame listed in Mesh Setup for a Single Moving Reference Frame (p. 538) apply to multiple reference frames as well.

1. Select the Velocity Formulation to be used in the General Task Page (p. 1888): either Absolute or Relative. (For details, see Choosing the Relative or Absolute Velocity Formulation (p. 541).)

General

(Note that this step is irrelevant if you are using one of the density-based solution algorithms; these algorithms always use an absolute velocity formulation.)

2. For each cell zone in the domain, specify its translational velocity and/or its angular velocity ($\omega$) and the axis about which it rotates.
Cell Zones Conditions

a. If the zone is moving, or if you plan to specify cylindrical velocity or flow-direction components at inlets to the zone, you must define the axis of rotation of the frame of reference. In the Fluid or Solid dialog box, specify the Rotation-Axis Origin and Rotation-Axis Direction under the Reference Frame tab.

b. In the Fluid (Figure 9.4: The Fluid Dialog Box Displaying Frame Motion Inputs (p. 540)) or Solid dialog box, enable the Frame Motion option. Set the Speed under Rotational Velocity and/or the X, Y, and Z components of the Translational Velocity in the expanded portion of the dialog box under the Reference Frame tab.

Note that the speed can be specified as a constant value or a transient profile. The transient profile may be in a file format, as described in Defining Transient Cell Zone and Boundary Conditions (p. 388), or a UDF macro, described in DEFINE_TRANSIENT_PROFILE. Specifying the individual velocities as either a profile or a UDF allows you to specify a specific input of the frame motion individually. However, you can also specify the frame motion inputs via a single user-defined function that uses the UDF macro DEFINE_ZONE_MOTION. This may prove to be quite convenient if you are modeling a more complicated motion of the moving reference frame, where the hooking of many different user-defined functions or profiles can be cumbersome.

Note

If you decide to hook a UDF, then you will no longer have access to the rotation axis origin and direction, or the velocities.

Details about these inputs are presented in Inputs for Fluid Zones (p. 216) and in Inputs for Solid Zones (p. 221). Details about the zone motion UDF can be found in DEFINE_ZONE_MOTION in the UDF Manual.

c. To switch between the MRF and moving mesh models, click the Copy To Mesh Motion for zones with a moving frame of reference and Copy to Frame Motion for zones with moving meshes to transfer motion variables, such as the axes, frame origin, and velocity components between the two models.

The variables used for the origin, axis, and velocity components, as well as for the UDF DEFINE_ZONE_MOTION will be copied. This is particularly useful if you are doing a steady-state MRF simulation to obtain an initial solution for a transient Moving Mesh simulation in a turbomachine.

3. Define the velocity boundary conditions at walls. You can choose to define either an absolute velocity or a velocity relative to the velocity of the adjacent cell zone specified in step 2.

If the wall is moving at the speed of the moving frame (and hence stationary relative to the moving frame), it is convenient to specify a relative angular velocity of zero. Likewise, a wall that is stationary in the non-moving frame of reference should be given a velocity of zero in the absolute reference frame. Specifying the wall velocities in this manner obviates the need to modify these inputs later if a change is made in the rotational velocity of the fluid zone.

An example for which you would specify a relative velocity is as follows: If an impeller is defined as wall-3 and the fluid region within the impeller’s radius is defined as fluid-5, you would need to specify the angular velocity and axis of rotation for fluid-5 and then assign wall-3 a relative velocity of 0. If you later wanted to model a different angular velocity for the impeller, you would need to
change only the angular velocity of the fluid region; you would not need to modify the wall velocity conditions.

Details about these inputs are presented in Velocity Conditions for Moving Walls (p. 311).

4. Define the boundary conditions at the inlets, as described in Boundary Conditions (p. 255). For velocity inlets, you can choose to define either absolute velocities or velocities relative to the motion of the adjacent cell zone (specified in step 2). Likewise, the total pressure and flow direction can be prescribed in absolute or relative frames for pressure inlets.

Details about these inputs are presented in Defining the Flow Direction (p. 265) and Defining the Velocity (p. 272).

5. Define the mesh interfaces in the Create/Edit Mesh Interfaces Dialog Box (p. 2172) (Figure 10.10: The Create/Edit Mesh Interfaces Dialog Box (p. 567)).

Mesh Interfaces → Create/Edit...

To learn how to use the Create/Edit Mesh Interfaces dialog box, see Using a Non-Conformal Mesh in ANSYS Fluent (p. 159).

6. Initialize the solution using an absolute frame of reference (Figure 9.8: The Solution Initialization Task Page for Moving Reference Frames (p. 551)).
Select the **Absolute** option under **Reference Frame**. If the **Relative to Cell Zone** option is selected, the initial flow field can contain discontinuities, which can cause convergence problems in the first few iterations.

**Figure 9.8: The Solution Initialization Task Page for Moving Reference Frames**

### Solution Initialization

**Initialization Methods**

### 9.3.4.2. Setting Up the Mixing Plane Model

The model inputs for mixing planes are presented in this section. Only those steps relevant specifically to the setup of a mixing plane problem are listed here. Note that the use of wall and periodic boundaries in a mixing plane model is consistent with their use when the model is not active.

1. Select the **Absolute** or **Relative Velocity Formulation** in the **General Task Page** (**p. 1888**), when the pressure-based solver is enabled.
**General**

**Important**

When the density-based solver is enabled, only the **Absolute Velocity Formulation** can be used with the mixing plane model.

2. **Cell Zones Conditions**
   
a. If the zone is rotating, or if you plan to specify cylindrical-velocity or flow-direction components at inlets to the zone, you must define the axis of rotation for the frame of reference. In the **Fluid** dialog box or **Solid** dialog box (p. 2092), specify the **Rotation-Axis Origin** and **Rotation-Axis Direction** under the **Reference Frame** tab.
   
b. In the **Fluid** (Figure 9.4: The Fluid Dialog Box Displaying Frame Motion Inputs (p. 540)) or **Solid** dialog box, enable the **Frame Motion** option and then set the **Speed** under **Rotational Velocity** and/or the X, Y, and Z components of the **Translational Velocity** in the expanded portion of the dialog box under the **Reference Frame** tab.

**Important**

It is important to define the axis of rotation for the cell zones on both sides of the mixing plane interface, including the stationary zone.

3. Define the velocity boundary conditions at walls, as described in step 3 of **Setting Up Multiple Reference Frames** (p. 548).

4. Define the boundary conditions at the inlets, as described in **Boundary Conditions** (p. 255). For velocity inlets, you can choose to define either absolute velocities or velocities relative to the motion of the adjacent cell zone (specified in step 2). For pressure inlets and mass flow inlets, the specification of the flow direction and total pressure will always be absolute, because the absolute velocity formulation is always used for mixing plane calculations. For a mass flow inlet, you do not need to specify the mass flow rate or mass flux. ANSYS Fluent will automatically select the **Mass Flux with Average Mass Flux** specification method and set the correct values when you create the mixing plane, as described in **More About Mass Flux and Average Mass Flux** (p. 279).

Details about these inputs are presented in **Defining the Flow Direction** (p. 265), **Defining the Velocity** (p. 272), and **Inputs at Mass Flow Inlet Boundaries** (p. 277).

**Important**

Note that the outlet boundary zone at the mixing plane interface must be defined as a pressure outlet, and the inlet boundary zone at the mixing plane interface must be defined as either a velocity inlet (incompressible flow only), a pressure inlet, or a mass flow inlet. The overall inlet and exit boundary conditions can be any suitable combination permitted by the solver (for example, velocity inlet, pressure inlet, or mass flow inlet; pressure outlet). Keep in mind, however, that if mass conservation across the mixing plane is important,
you must use a mass flow inlet as the downstream boundary; strict mass conservation is *not* maintained across the mixing plane when you use a velocity inlet or pressure inlet.

5. Define the mixing planes in the **Mixing Planes Dialog Box (p. 2430)** (Figure 9.9: The Mixing Planes Dialog Box (p. 553)).

**Define → Mixing Planes...**

**Figure 9.9: The Mixing Planes Dialog Box**

![Mixing Planes Dialog Box](image)

- Specify the two zones that comprise the mixing plane by selecting an upstream zone in the **Upstream Zone** list and a downstream zone in the **Downstream Zone** list. It is essential that the correct pairs be chosen from these lists (that is, that the boundary zones selected lie on the mixing plane interface). You can check this by displaying the mesh.

**General → Display...**

- (3D only) Indicate the geometry of the mixing plane interface by choosing one of the options under **Mixing Plane Geometry**.

A **Radial** geometry signifies that information at the mixing plane interface is to be circumferentially averaged into profiles that vary in the radial direction, for example, \( p(r) \), \( T(r) \). This is the case for axial-flow machines, for example.
An **Axial** geometry signifies that circumferentially averaged profiles are to be constructed that vary in the axial direction, for example, $p(x)$, $T(x)$. This is the situation for a radial-flow device.

---

**Important**

Note that the radial direction is normal to the rotation axis for the fluid zone and the axial direction is parallel to the rotation axis.

---

c. (3D only) Set the number of **Interpolation Points**. This is the number of radial or axial locations used in constructing the boundary profiles for circumferential averaging. You should choose a number that approximately corresponds to the resolution of the surface mesh in the radial or axial direction. Note that while you can use more points if you want, the resolution of the boundary profile will only be as fine as the resolution of the surface mesh itself.

In 2D the flow data is averaged over the entire interface to create a profile consisting of a single data point. For this reason you do not need to set the number of **Interpolation Points** or select a **Mixing Plane Geometry** in 2D.

d. Set the **Global Parameters** for the mixing plane.

i. Select the **Averaging Method**. The **Area** averaging method is the default method. For detailed information about each of the **Area**, **Mass**, or **Mixed-Out** options, see Choosing an Averaging Method in the Theory Guide.

ii. Set the **Under-Relaxation** parameter. It is sometimes desirable to under-relax the changes in boundary values at mixing planes as these may change very rapidly during the early iterations of the solution and cause the calculation to diverge. The changes can be relaxed by specifying an under-relaxation less than 1. The new boundary profile values are then computed using

$$
\phi_{\text{new}} = \phi_{\text{old}} + \alpha \left( \phi_{\text{calculated}} - \phi_{\text{old}} \right)
$$

(9.1)

where $\alpha$ is the under-relaxation factor. Once the flow field is established, the value of $\alpha$ can be increased.

iii. Click **Apply** to set the **Global Parameters**. If the **Default** button is visible to the right of the **Apply** button, clicking the **Default** button will return **Global Parameters** back to their default values. The **Default** button will then change to be a **Reset** button. Clicking the **Reset** button will change the **Global Parameters** back to the values that were last applied.

e. Click **Create** to create a new mixing plane. ANSYS Fluent will name the mixing plane by combining the names of the zones selected as the **Upstream Zone** and **Downstream Zone** and enter the new mixing plane in the **Mixing Plane** list.

If you create an incorrect mixing plane, you can select it in the **Mixing Plane** list and click the **Delete** button to delete it.

**9.3.4.2.1. Modeling Options**

There are two options available for use with the mixing plane model: a fixed pressure level for incompressible flows, and the swirl conservation described in **Swirl Conservation** in the Theory Guide.
9.3.4.2.1.1. Fixing the Pressure Level for an Incompressible Flow

For certain turbomachinery configurations, such as a torque converter, there is no fixed-pressure boundary when the mixing plane model is used. The mixing plane model is usually used to model the three interfaces that connect the components of the torque converter. In this configuration, the pressure is no longer fixed. As a result, the pressure may float unbounded, making it difficult to obtain a converged solution.

To resolve this problem, ANSYS Fluent offers an option for fixing the pressure level. When this option is enabled, ANSYS Fluent will adjust the gauge pressure field after each iteration by subtracting from it the pressure value in the cell closest to the Reference Pressure Location in the Operating Conditions Dialog Box (p. 2095).

**Important**

This option is available only for incompressible flows calculated using the pressure-based solver.

To enable the fixed pressure option, use the `fix-pressure-level` text command:

```plaintext
define → mixing-planes → set → fix-pressure-level
```

9.3.4.2.1.2. Conserving Swirl Across the Mixing Plane

Conservation of swirl is important for applications such as torque converters (Swirl Conservation in the Theory Guide). If you want to enable swirl conservation across the mixing plane, you can use the commands in the `conserve-swirl` text menu:

```plaintext
define → mixing-planes → set → conserve-swirl
```

To turn on swirl conservation, use the `enable?` text command. Once the option is turned on, you can ask the solver to report information about the swirl conservation during the calculation. If you turn on `verbosity?`, ANSYS Fluent will report for every iteration the zone ID for the zone on which the swirl conservation is active, the upstream and downstream swirl integration per zone area, and the ratio of upstream to downstream swirl integration before and after the correction.

To obtain a report of the swirl integration at every pressure inlet, pressure outlet, velocity inlet, and mass flow inlet in the domain, use the `report-swirl-integration` command. You can use this information to determine the torque acting on each component of the turbomachinery according to Equation 2.22 (in the Theory Guide).

9.3.4.2.1.3. Conserving Total Enthalpy Across the Mixing Plane

One of the options available in the mixing plane model is to conserve total enthalpy across the mixing plane. This is a desirable feature because global parameters such as efficiency are directly related to the change in total enthalpy across a blade row or stage.

The procedure for ensuring conservation of total enthalpy simply involves adjusting the downstream total temperature profile such that the integrated total enthalpy matches the upstream integrated total enthalpy.

If you want to enable total enthalpy conservation, you can use the commands in the `conserve-total-enthalpy` text menu:
To turn on total enthalpy conservation, use the `enable?` text command. Once the option is turned on, you can ask the solver to report information about the total enthalpy conservation during the calculation. If you turn on `verbosity?`, ANSYS Fluent will report at every iteration the zone ID for the zone on which the total enthalpy conservation is active, the upstream and downstream heat flux, and the ratio of upstream to downstream heat flux.

### 9.3.5. Solution Strategies for MRF and Mixing Plane Problems

#### 9.3.5.1. MRF Model

For multiple moving reference frames, follow the guidelines presented in Solution Strategies for a Single Moving Reference Frame (p. 542) for a single moving reference frame. Keep in mind that with multiple zones, the possibility exists of interaction between moving and stationary components. This will manifest itself as poor or oscillatory convergence. In such cases, it is strongly recommend that the sliding mesh approach be used to compute the flowfield in order to resolve the unsteady interactions.

#### 9.3.5.2. Mixing Plane Model

It should be emphasized that the mixing plane model is a reasonable approximation so long as there is no significant reverse flow in the vicinity of the mixing plane. If significant reverse flow occurs, the mixing plane will not be a satisfactory model of the actual flow. In a numerical simulation, reverse flow often occurs during the early stages of the computation even though the flow at convergence is not reversed. Therefore, it is helpful in these situations to first obtain a provisional solution using fixed conditions at the rotor-stator interface. The mixing plane model can then be enabled and the solution run to convergence.

If you are using the mass or mixed-out averaging method and you are experiencing convergence problems in the presence of severe reverse flow, initialize your solution using the default area-averaging method, then switch to mass or mixed-out averaging after the reverse flow dies out.

Under-relaxing the changes in the mixing plane boundary values can also help in troublesome situations. In many cases, setting the under-relaxation factor to a value less than 1 can be helpful. Once the flow field is established, you can gradually increase the under-relaxation factor.

### 9.3.6. Postprocessing for MRF and Mixing Plane Problems

When you solve a problem using the multiple reference frame or mixing plane model, you can plot or report both absolute and relative velocities. For all velocity parameters (for example, **Velocity Magnitude** and **Mach Number**), corresponding relative values will be available for postprocessing (for example, **Relative Velocity Magnitude** and **Relative Mach Number**). These variables are contained in the **Velocity...** category of the variable selection drop-down list that appears in postprocessing dialog boxes. Relative values are also available for postprocessing of total pressure, total temperature, and any other parameters that include a dynamic contribution dependent on the reference frame (for example, **Relative Total Pressure**, **Relative Total Temperature**).

**Important**

Relative velocities are relative to the translational/rotational velocity of the “reference zone” (specified in the **Reference Values** task page (see Reference Values Task Page (p. 2202))). The
velocity of the reference zone is the velocity defined in the Fluid Dialog Box (p. 2085) for that zone.

When plotting velocity vectors, you can choose to plot vectors in the absolute frame (the default), or you can select Relative Velocity in the Vectors of drop-down list in the Vectors Dialog Box (p. 2286) to plot vectors relative to the translational/rotational velocity of the “reference zone” (specified in the Reference Values Task Page (p. 2202)). If you plot relative velocity vectors, you might want to color the vectors by relative velocity magnitude (by choosing Relative Velocity Magnitude in the Color by list); by default they will be colored by absolute velocity magnitude.

You can also generate a plot of circumferential averages in ANSYS Fluent. This allows you to find the average value of a quantity at several different radial or axial positions in your model. ANSYS Fluent computes the average of the quantity over a specified circumferential area, and then plots the average against the radial or axial coordinate. For more information on generating XY plots of circumferential averages, see XY Plots of Circumferential Averages (p. 1705).

For details about turbomachinery-specific postprocessing features see Turbomachinery Postprocessing (p. 1713).
Chapter 10: Modeling Flows Using Sliding and Dynamic Meshes

This chapter describes the setup and use of the sliding and dynamic mesh models in ANSYS Fluent. To learn more about the theory of sliding meshes in ANSYS Fluent, see Sliding Mesh Theory in the Theory Guide. For more information about the theory behind dynamic meshes in ANSYS Fluent, see Dynamic Mesh Theory in the Theory Guide.

Understanding and using the sliding and deforming mesh models is presented in the following sections:

10.1. Introduction
10.2. Sliding Mesh Examples
10.3. The Sliding Mesh Technique
10.4. Sliding Mesh Interface Shapes
10.5. Using Sliding Meshes
10.6. Using Dynamic Meshes

10.1. Introduction

The sliding mesh model allows you to set up a problem in which separate zones move relative to each other. The motion can be translational or rotational. The relative motion of stationary and moving components (for example, in a rotating machine) will give rise to transient interactions. Often, the transient solution that is sought in a sliding mesh simulation is time-periodic. That is, the transient solution repeats with a period related to the speeds of the moving domains.

The dynamic mesh model allows you to move the boundaries of a cell zone relative to other boundaries of the zone, and to adjust the mesh accordingly. The boundaries can move rigidly with respect to each other (that is, linear or rotational motion), and/or deform.

When deciding whether to use a sliding mesh versus a dynamic mesh, consider the following:

• Many problems could be solved by either approach.

• If the problem does not involve mesh deformation, the sliding mesh model is recommended, as it is simpler and more efficient.

• The dynamic mesh method must be used if the mesh is deforming, or if the mesh motion is a function of the solution (for example, the six degree of freedom solver).

For examples of typical sliding mesh and dynamic mesh problems, see Introduction in the Theory Guide.

10.2. Sliding Mesh Examples

When a time-accurate solution (rather than a time-averaged solution) for rotor-stator interaction is desired, you must use the sliding mesh model to compute the unsteady flow field. The sliding mesh model is the most accurate method for simulating flows in multiple moving reference frames, but also the most computationally demanding.

Most often, the unsteady solution that is sought in a sliding mesh simulation is time-periodic. That is, the unsteady solution repeats with a period related to the speeds of the moving domains. However,
you can model other types of transients, including translating sliding mesh zones (for example, two cars or trains passing in a tunnel, as shown in Figure 10.1: Two Passing Trains in a Tunnel (p. 560)). Note that the sliding mesh can be modeled using periodic boundaries (Figure 10.2: Rotor-Stator Interaction (Stationary Guide Vanes with Rotating Blades) (p. 560)) or a circular/cylindrical interface (Figure 10.3: Blower (p. 561)).

**Figure 10.1: Two Passing Trains in a Tunnel**

![Two Passing Trains in a Tunnel](image1)

**Figure 10.2: Rotor-Stator Interaction (Stationary Guide Vanes with Rotating Blades)**

![Rotor-Stator Interaction](image2)
Note that for flow situations where there is no interaction between stationary and moving parts (for example, when there is only a rotor), it is not necessary to use a sliding mesh, and the moving reference frame model is recommended. (See Flow in a Moving Reference Frame for details.) If you are interested in a steady approximation of the interaction, you may use the multiple reference frame model or the mixing plane model, as described in The Multiple Reference Frame Model and The Mixing Plane Model in the Theory Guide.

10.3. The Sliding Mesh Technique

In the sliding mesh technique, two or more cell zones are used. (If you generate the mesh in each zone independently, you must merge the mesh files prior to starting the calculation, as described in Reading Multiple Mesh/Case/Data Files in the User's Guide.) Each cell zone is bounded by at least one “interface zone” where it meets the opposing cell zone. The interface zones of adjacent cell zones are associated with one another to form a “mesh interface.” The two cell zones will move relative to each other along the mesh interface.

During the calculation, the cell zones slide (that is, rotate or translate) relative to one another along the mesh interface in discrete steps. Figure 10.4: Initial Position of the Meshes (p. 562) and Figure 10.5: Rotor Mesh Slides with Respect to the Stator (p. 562) show the initial position of two meshes and their positions after some translation has occurred. Note that all non-conformal interfaces will be automatically updated (if necessary) by ANSYS Fluent when the mesh is updated.

As the rotation or translation takes place, node alignment along the mesh interface is not required. Since the flow is inherently unsteady, a time-dependent solution procedure is required.
10.4. Sliding Mesh Interface Shapes

The mesh interface and the associated interface zones can be any shape, provided that the two interface boundaries are based on the same geometry. Figure 10.6: 2D Linear Mesh Interface (p. 563) shows an example with a linear mesh interface and Figure 10.7: 2D Circular-Arc Mesh Interface (p. 563) shows a circular-arc mesh interface. (In both figures, the mesh interface is designated by a dashed line.)
If Figure 10.6: 2D Linear Mesh Interface (p. 563) was extruded to 3D, the resulting sliding interface would be a planar rectangle; if Figure 10.7: 2D Circular-Arc Mesh Interface (p. 563) was extruded to 3D, the resulting interface would be a cylinder. Figure 10.8: 3D Conical Mesh Interface (p. 564) shows an example that would use a conical mesh interface. (The slanted, dashed lines represent the intersection of the conical interface with a 2D plane.)
For an axial rotor/stator configuration, in which the rotating and stationary parts are aligned axially instead of being concentric (see Figure 10.9: 3D Planar-Sector Mesh Interface), the interface will be a planar sector. This planar sector is a cross-section of the domain perpendicular to the axis of rotation at a position along the axis between the rotor and the stator.
10.5. Using Sliding Meshes

This section describes how to use sliding meshes, including restrictions and constraints, problem setup, solution strategies, and postprocessing.

10.5.1. Requirements and Constraints

10.5.2. Setting Up the Sliding Mesh Problem

10.5.3. Solution Strategies for Sliding Meshes

10.5.4. Postprocessing for Sliding Meshes

10.5.1. Requirements and Constraints

Before beginning the problem setup in ANSYS Fluent, be sure that the mesh you have created meets the following requirements:

• The mesh must have a different cell zone for each portion of the domain that is sliding at a different speed.

• The mesh interface must be situated such that there is no motion normal to it.

• The mesh interface can be any shape (including a non-planar surface, in 3D), provided that the two interface boundaries are based on the same geometry. If there are sharp features in the mesh (for example, 90-degree angles), it is especially important that both sides of the interface closely follow that feature.

• If you create a single mesh with multiple cell zones, you must be sure that each cell zone has a distinct face zone on the sliding boundary. The face zones for two adjacent cell zones will have the same position and shape, but one will correspond to one cell zone and one to the other. (Note that it is also possible to create a separate mesh file for each of the cell zones, and then merge them as described in Reading Multiple Mesh/Case/Data Files (p. 143).)

• If you are modeling a rotor/stator geometry using periodicity, the periodic angle of the mesh around the rotor blade(s) must be the same as that of the mesh around the stationary vane(s).

• All periodic zones must be correctly oriented (either rotational or translational) before you create the mesh interface.

• Note the following limitations if you want to use the periodic repeats option as part of the mesh interface:
  – The edges of the second interface zone must be offset from the corresponding edges of the first interface zone by a uniform amount (either a uniform translational displacement or a uniform rotation angle).
  – Some portion of the two interface zones must overlap (that is, be spatially coincident).
  – The non-overlapping portions of the interface zones must have identical shape and dimensions at all times during the mesh motion.
  – One pair of conformal periodic zones must be adjacent to each of the interface zones. For example, when you calculate just one channel and blade of a fan, turbine, etc., you must have conformal periodics on either side of the interface threads. This will not work with non-conformal periodics.

  Note that for 3D cases, you cannot have more than one pair of conformal periodic zones adjacent to each of the interface zones.

• You must not have a single sliding mesh interface where part of the interface is made up of a coupled two-sided wall, while another part is not coupled (that is, the normal interface treatment). In such cases,
you must break the interface up into two interfaces: one that is a coupled interface, and the other that is a standard fluid-fluid interface. See Using a Non-Conformal Mesh in ANSYS Fluent (p. 159) for information about creating coupled interfaces.

For details about these restrictions and general information about how the sliding mesh model works in ANSYS Fluent, see The Sliding Mesh Technique (p. 561).

10.5.2. Setting Up the Sliding Mesh Problem

The steps for setting up a sliding mesh problem are listed below. (Note that this procedure includes only those steps necessary for the sliding mesh model itself; you must set up other models, boundary conditions, etc. as usual.)

1. Enable the appropriate option for modeling transient flow in the General Task Page (p. 1888). (See Performing Time-Dependent Calculations (p. 1462) for details about the transient modeling capabilities in ANSYS Fluent.)

2. Set the cell zone conditions for the sliding motion:

   - **Cell Zones Conditions**

   In the Solid Dialog Box (p. 2092) or Fluid Dialog Box (p. 2085) of each moving fluid or solid zone, enable the Mesh Motion option and set the translational and/or rotational velocity under the Mesh Motion tab. (Note that a solid zone cannot move at a different speed than an adjacent fluid zone.)

   **Important**

   Note that simultaneous translation and rotation can be modeled only if the rotation axis and the translation direction are the same (that is, the origin is fixed).

   Note that the speed can be specified as a constant value or a transient profile. The transient profile may be in a file format, as described in Defining Transient Cell Zone and Boundary Conditions (p. 388), or a UDF macro, described in DEFINE_TRANSIENT_PROFILE in the UDF Manual. Specifying the individual velocities as either a profile or a UDF allows you to specify a single component of the frame motion individually. However, you can also specify the frame motion using a user-defined function. This may prove to be quite convenient if you are modeling a more complicated motion of the moving reference frame, where the hooking of many different user-defined functions or profiles can be cumbersome.

   **Note**

   If you decide to hook a UDF, then you will no longer have access to the rotation axis origin and direction, or the velocities.

3. Set the boundary conditions for the sliding motion:

   - **Boundary Conditions**
Change the zone **Type** of the interface zones of adjacent cell zones to **interface** in the **Boundary Conditions Task Page** (p. 2102).

By default, the velocity of a wall is set to zero relative to the motion of the adjacent mesh. For walls bounding a moving mesh this results in a “no-slip” condition in the reference frame of the mesh. Therefore, you need not modify the wall velocity boundary conditions unless the wall is stationary in the absolute frame, and therefore moving in the relative frame. See **Velocity Conditions for Moving Walls** (p. 311) for details about wall motion.

See **Cell Zone and Boundary Conditions** (p. 201) for details about inputting cell zone and boundary conditions.

4. Define the mesh interfaces in the **Create/Edit Mesh Interfaces Dialog Box** (p. 2172) (Figure 10.10: The Create/Edit Mesh Interfaces Dialog Box (p. 567)).

   ![Mesh Interfaces → Create/Edit...](image)

**Figure 10.10: The Create/Edit Mesh Interfaces Dialog Box**

- Enter a name for the interface in the **Mesh Interface** field.
- Specify the two interface zones that comprise the mesh interface by selecting one or more zones in the **Interface Zone 1** list and one or more zones in the **Interface Zone 2** list. (The order does not matter.)
- Enable the desired **Interface Options**, if appropriate. There are two options relevant for sliding meshes:
• Enable **Periodic Repeats** when each of the two cell zones has a single pair of conformal periodics adjacent to the interface (see Figure 5.31: Translational Non-Conformal Interface with the Periodic Repeats Option (p. 153)). This option is typically used when simulating the interface between a rotor and stator. See Non-Conformal Meshes (p. 148) for further details.

**Important**

**Periodic Repeats** is not a valid option when more than one zone is selected in each Interface Zone.

• Enable **Coupled Wall** if you would like to model a thermally coupled wall between two fluid zones that share a sliding mesh interface.

**Important**

Note that the following interfaces are coupled by default:

– the interface between a solid zone and fluid zone
– the interface between a solid zone and solid zone

Therefore, no action is required in the Create/Edit Mesh Interfaces Dialog Box (p. 2172) to set up such interfaces.

• Enable the **Matching** option if only interface interior zones should be created, that is, the interface boundary zones should be empty because the interface zones on both sides are aligned. With the Matching option, even interface zones that are not perfectly aligned are treated as if they would be, however, if the discrepancy between the interface zones on both sides exceeds default thresholds, then warning messages will be displayed. Note that the Matching option is also compatible with periodic boundary conditions. See Matching Option (p. 155) for more information about the recommended uses of this option.

d. Click **Create** to create a new mesh interface.

For non-periodic interfaces, ANSYS Fluent will create boundary zones for the interface, which will appear under **Boundary Zone 1** and **Boundary Zone 2**. You can use the Boundary Conditions Task Page (p. 2102) to change them to another zone type (for example, pressure far-field, symmetry, pressure outlet).

If you have enabled the **Coupled Wall** option, ANSYS Fluent will also create wall interface zones, which will appear under **Interface Wall Zone 1** and **Interface Wall Zone 2**.

If you create an incorrect mesh interface, you can select it in the **Mesh Interface** list and click the **Delete** button to delete it. (Any boundary zones that were created when the interface was created will also be deleted.)

After a **Mesh Interface** is defined, you can select the appropriate mesh interface and click the **Draw** button to display the zones under **Interface Zone 1** and **Interface Zone 2** together as defined by the **Mesh Interface**. This is particularly useful if you want to check the location of the interface zones prior to setting up a mesh interface.
5. Preview the mesh motion using the **Zone Motion** dialog box, which can be opened from the **Run Calculation** task page.

![Run Calculation ➤ Preview Mesh Motion...](image)

For details about using the **Zone Motion** dialog box, see Previewing the Dynamic Mesh (p. 667).

---

**Important**

When you have completed the problem setup, you should save an initial case file so that you can easily return to the original mesh position (that is, the positions before any sliding occurs). The mesh position is stored in the case file, so case files that you save at different times during the transient calculation will contain meshes at different positions.

---

**Important**

If you desire to go from an MRF model setup to a sliding mesh setup, use the following text command:

```
mesh → modify-zones → mrf-to-sliding-mesh
```

To successfully switch from an MRF to a sliding mesh, you must provide the ID of the fluid zone. ANSYS Fluent identifies all the zones belonging to this fluid zone, as well as fluid zones shared in the domain. ANSYS Fluent then splits these zones into walls, after which the walls are slit converted to interfaces. ANSYS Fluent then changes the cell zone condition of the fluid zone to **Moving Mesh** in the Fluid Dialog Box (p. 2085). Note that the interface between the cells zones should be an interior boundary. You do not need to do this if you have already created a mesh interface. The sliding mesh solution tends to be more robust than the MRF solution.

---

### 10.5.3. Solution Strategies for Sliding Meshes

You will begin the sliding mesh calculation by initializing the solution (as described in Initializing the Entire Flow Field Using Standard Initialization (p. 1445)) and then specifying the time step size and number of time steps in the Run Calculation Task Page (p. 2269), as for any other transient calculation. (See Performing Time-Dependent Calculations (p. 1462) for details about time-dependent solutions.) Note that the time step size in the initial case file is saved without clicking **Calculate**. ANSYS Fluent will iterate on the current time step solution until satisfactory residual reduction is achieved, or the maximum number of iterations per time step is reached. When it advances to the next time step, the cell and wall zones will automatically be moved according to the specified translational or rotational velocities (as discussed in the previous section). The new interface-zone intersections will be computed automatically, and resultant interior/periodic/external boundary zones will be updated.

Note that you can run the MRF case using mesh interfaces with an appreciable loss of accuracy, doing so makes it easier to later on convert to a sliding mesh.

---

**Note**

The sliding mesh can be initialized with an MRF solution (rather using Standard or Hybrid initializations).
It is recommended that you preview the sliding mesh motion (as described in Previewing the Dynamic Mesh (p. 667)) before beginning your calculation. This can catch problems with the motion specification(s) before you begin the CFD calculation. Remember to save the case and initial data files before doing a mesh preview since the mesh position is altered once you do the preview. You can reread the initial condition case/data files to get back to the original mesh position.

10.5.3.1. Saving Case and Data Files

ANSYS Fluent’s automatic saving of case and data files (see Automatic Saving of Case and Data Files (p. 49)) can be used with the sliding mesh model. This provides a convenient way for you to save results at successive time steps for later postprocessing.

Important

You must save a case file each time you save a data file because the mesh position is stored in the case file. Since the mesh position changes with each time step, reading data for a given time step will require the case file at that time step so that the mesh will be in the proper position. You should also save your initial case file so that you can easily return to the mesh’s original position to restart the solution if desired.

Important

If you are planning to solve your sliding mesh model in several stages, whereby you run the calculation for some period of time, save case and data files, exit ANSYS Fluent, start a new ANSYS Fluent session, read the case and data files, continue the calculation for some time, save case and data files, exit ANSYS Fluent, and so on, there may be some distortion in the mesh with each subsequent continuation of the calculation. To avoid this problem, you can delete the mesh interface before saving the case file, and then create it again after you read the case file into a new ANSYS Fluent session.

10.5.3.2. Time-Periodic Solutions

For some problems (for example, rotor-stator interactions), you may be interested in a time-periodic solution. That is, the startup transient behavior may not be of interest to you. Once this startup phase has passed, the flow will start to exhibit time-periodic behavior. If \( T \) is the period of unsteadiness, then for some flow property \( \phi \) at a given point in the flow field:

\[
\phi(t) = \phi(t + NT) \quad (N = 1, 2, 3, \ldots)
\]  

(10.1)

For rotating problems, the period (in seconds) can be calculated by dividing the sector angle of the domain (in radians) by the rotor speed (in radians/sec): \( T = \theta / \Omega \). For 2D rotor-stator problems, \( T = P / \nu_b \), where \( P \) is the pitch and \( \nu_b \) is the blade speed. The number of time steps in a period can be determined by dividing the time period by the time step size. When the solution field does not change from one period to the next (for example, if the change is less than 5%), a time-periodic solution has been reached.

To determine how the solution changes from one period to the next, you must compare the solution at some point in the flow field over two periods. For example, if the time period is 10 seconds, you can compare the solution at a given point after 22 seconds with the solution after 32 seconds to see if a time-periodic solution has been reached. If not, you can continue the calculation for another period and compare the solutions after 32 and 42 seconds, and so on until you see little or no change from one period to the next. You can also track global quantities, such as lift and drag coefficients and mass...
flow, in the same manner. Figure 10.11: Lift Coefficient Plot for a Time-Periodic Solution (p. 571) shows a lift coefficient plot for a time-periodic solution.

**Figure 10.11: Lift Coefficient Plot for a Time-Periodic Solution**

The final time-periodic solution is independent of the time steps taken during the initial stages of the solution procedure. You can therefore define “large” time steps in the initial stages of the calculation, since you are not interested in a time-accurate solution for the startup phase of the flow. Starting out with large time steps will allow the solution to become time-periodic more quickly. As the solution becomes time-periodic, however, you should reduce the time step in order to achieve a time-accurate result.

**Important**

If you are solving with second-order time accuracy, the temporal accuracy of the solution will be affected if you change the time step during the calculation. You may start out with larger time steps, but you should not change the time step by more than 20% during the solution process. You should not change the time step at all during the last several periods to ensure that the solution has approached a time-periodic state.

### 10.5.4. Postprocessing for Sliding Meshes

Postprocessing for sliding mesh problems is the same as for other transient problems. You will read in the case and data file for the time of interest and display and report results as usual. For spatially-periodic problems, you may want to use periodic repeats (set in the Views Dialog Box (p. 2323), as described in Modifying the View (p. 1660)) to display the geometry. Figure 10.12: Contours of Static Pressure for the Rotor-Stator Example (p. 572) shows the flow field for the rotor-stator example in Figure 10.4: Initial Position of the Meshes (p. 562)) at one instant in time, using 1 periodic repeat.
When displaying velocity vectors, note that absolute velocities (that is, velocities in the inertial, or laboratory, reference frame) are displayed by default. You may also choose to display relative velocities by selecting **Relative Velocity** in the **Vectors of** drop-down list in the **Vectors Dialog Box** (p. 2286). In this case, velocities relative to the translational/rotational velocity of the “reference zone” (specified in the **Reference Values Task Page** (p. 2202)) will be displayed. (The velocity of the reference zone is the velocity defined in the **Fluid Dialog Box** (p. 2085) for that zone.)

Note that you cannot create zone surfaces for the intersection boundaries (that is, the interior/periodic/external zones created from the intersection of the interface zones). You may instead create zone surfaces for the interface zones. Data displayed on these surfaces will be “one-sided”. That is, nodes on the interface zones will “see” only the cells on one side of the mesh interface, and slight discontinuities may appear when you plot contour lines across the interface. Note also that, for non-planar interface shapes in 3D, you may see small gaps in your plots of filled contours. These discontinuities and gaps are only graphical in nature. The solution does not have these discontinuities or gaps. To eliminate these discontinuities for postprocessing purposes only, you can use the **define/mesh-interfaces/enforce-continuity-after-bc**? text command, which will ensure that continuity will take precedence over the boundary condition.

You can also generate a plot of circumferential averages in ANSYS Fluent. This allows you to find the average value of a quantity at several different radial or axial positions in your model. ANSYS Fluent computes the average of the quantity over a specified circumferential area, and then plots the average against the radial or axial coordinate. For more information on generating XY plots of circumferential averages, see **XY Plots of Circumferential Averages** (p. 1705).

Sliding mesh results can be analyzed by employing the time averaging (or RMS averaging) option (**Data Sampling for Time Statistics**) in the **Run Calculation** task page. This will compute time averages for velocity, pressure, temperature, and turbulence. You must plan ahead since you have to engage the time averaging after the solution has become time-periodic and run for at least one period of the oscillating flow field.

---

**Figure 10.12: Contours of Static Pressure for the Rotor-Stator Example**

Contours of Static Pressure (psig) (Time=1.041E-01)
10.6. Using Dynamic Meshes

The steps for setting up a dynamic mesh problem are listed below. (Note that this procedure includes only those steps necessary for the dynamic mesh model itself; you must set up other models, cell zone conditions, boundary conditions, etc. as usual.)

1. Enable the appropriate option for modeling transient or steady flow in the General Task Page (p. 1888).

   General

   If your problem involves a steady flow, see Steady-State Dynamic Mesh Applications (p. 669) for important considerations.

2. Set cell zone conditions and boundary conditions as required in the Cell Zone Conditions Task Page (p. 2083) and Boundary Conditions Task Page (p. 2102).

   Cell Zone Conditions

   Boundary Conditions

   See Cell Zone and Boundary Conditions (p. 201) for information about inputting conditions. The correct wall velocity is set up automatically when a dynamic zone is created for a wall zone and the motion attributes are specified, so you will not specify wall motion in the Wall dialog box. If you create a moving dynamic cell zone, then all wall boundaries adjacent to that cell zone will, by default, impose the correct (moving) boundary conditions, and it is not necessary to declare these wall zones as dynamic zones. Note that if a wall boundary mesh is moving because it belongs to an adjacent moving dynamic cell zone, but the physical boundary conditions are such that the wall is actually not moving, then you will have to declare this boundary as a dynamic zone and specify that the mesh motion is not included in the boundary conditions (see Specifying the Motion of Dynamic Zones (p. 650)).

3. Enable the dynamic mesh model, and specify related parameters in the Dynamic Mesh Task Page (p. 2175).

   Dynamic Mesh ➔ Dynamic Mesh

   See Setting Dynamic Mesh Modeling Parameters (p. 575) for details.

4. Create the dynamic zones for your model, using the Dynamic Mesh Zones Dialog Box (p. 2190).

   Dynamic Mesh ➔ Create/Edit...

   See Specifying the Motion of Dynamic Zones (p. 650) for details.

5. You can display the motion of the moving zones with prescribed motion to verify the simulation setup.

   Dynamic Mesh ➔ Display Zone Motion...

   See Previewing the Dynamic Mesh (p. 667) for details.

6. If it is a transient simulation, define the events that will occur during the calculation.
Dynamic Mesh → Events...

See Defining Dynamic Mesh Events (p. 641) for details.

7. Save the case and data.

File → Write → Case & Data...

8. Preview your dynamic mesh setup (when the motion is a prescribed motion). See Steady-State Dynamic Mesh Applications (p. 669) for previewing your steady-state dynamic mesh motion and refer to Previewing the Dynamic Mesh (p. 667) for details.

Dynamic Mesh → Preview Mesh Motion...

9. Specify the pressure-velocity coupling scheme. For transient flow calculations, the PISO algorithm is recommended, as it is the most efficient for such cases (see PISO (p. 1416) for details).

10. Use the automatic saving feature to specify the file name and frequency with which case and data files should be saved during the solution process.

Calculation Activities → Edit... (Autosave Every)

See Automatic Saving of Case and Data Files (p. 49) for details about the use of this feature. This provides a convenient way for you to save results at successive time steps for later postprocessing.

---

Important

You must save a case file each time you save a data file because the mesh position is stored in the case file. Since the mesh position changes with each time step, reading data for a given time step will require the case file at that time step so that the mesh will be in the proper position. You should also save your initial case file so that you can easily return to the mesh’s original position to restart the solution if desired.

---

11. (optional) If you want to create a graphical animation of the mesh over time during the solution procedure, you can use the Calculation Activities Task Page (p. 2254) to set up the graphical displays that you want to use in the animation. See Animating the Solution (p. 1510) for details.

For additional information, see the following sections:
10.6.1. Setting Dynamic Mesh Modeling Parameters
10.6.2. Dynamic Mesh Update Methods
10.6.3. In-Cylinder Settings
10.6.4. Six DOF Solver Settings
10.6.5. Implicit Update Settings
10.6.6. Contact Detection Settings
10.6.7. Defining Dynamic Mesh Events
10.6.8. Specifying the Motion of Dynamic Zones
10.6.9. Previewing the Dynamic Mesh
10.6.10. Steady-State Dynamic Mesh Applications
10.6.1. Setting Dynamic Mesh Modeling Parameters

To enable the dynamic mesh model, enable **Dynamic Mesh** in the Dynamic Mesh Task Page (p. 2175) (Figure 10.13: The Dynamic Mesh Task Page (p. 575)).

![Figure 10.13: The Dynamic Mesh Task Page](image)

Then, enable the appropriate options in the **Options** group box. If you are modeling in-cylinder motion, enable the **In-Cylinder** option. If you are going to use the six degrees of freedom solver, then enable the **Six DOF** option. If you want to have the dynamic mesh updated during a time step (as opposed to just at the beginning of a time step), then enable the **Implicit Update** option. More information about these options and the related settings can be found in In-Cylinder Settings (p. 621), Six DOF Solver Settings (p. 636), and Implicit Update Settings (p. 638), respectively.

Next, you must select the appropriate mesh update methods in the **Mesh Methods** group box, and set the associated parameters, if relevant. See Dynamic Mesh Update Methods (p. 576) for details.

**Figure 10.13: The Dynamic Mesh Task Page**
10.6.2. Dynamic Mesh Update Methods

Three groups of mesh motion methods are available in ANSYS Fluent to update the volume mesh in the deforming regions subject to the motion defined at the boundaries:

- Smoothing Methods (p. 576)
- Dynamic Layering (p. 592)
- Remeshing Methods (p. 596)

Note that you can use ANSYS Fluent’s dynamic mesh models in conjunction with hanging node adaptation, with the exception of dynamic layering and face remeshing. For more information on hanging node adaptation, see Hanging Node Adaption in the Theory Guide.

Details on how to set up the various dynamic mesh update methods are provided in the sections that follow.

10.6.2.1. Smoothing Methods

When smoothing is used to adjust the mesh of a zone with a moving and/or deforming boundary, the interior nodes of the mesh move, but the number of nodes and their connectivity does not change. In this way, the interior nodes “absorb” the movement of the boundary. To enable smoothing, perform the following steps:

1. Enable the Smoothing option in the Mesh Methods group box of the Dynamic Mesh Task Page (p. 2175).
2. Click the Settings... button to open the Mesh Method Settings dialog box.
3. If you want spring-based smoothing, select **Spring/Laplace/Boundary Layer** from the **Method** list and define the settings in the **Parameters** group box, which are described in **Spring-Based Smoothing** (p. 578).

4. If you want diffusion-based smoothing (described in **Diffusion-Based Smoothing** (p. 581)):
   a. Select **Diffusion** from the **Method** list.
   b. Make a selection from the **Diffusion Function** drop-down list, to indicate whether you want the diffusion coefficient to be a function of the **boundary-distance** or the **cell-volume**. These functions and suggested values for the **Diffusion Parameter** are described in **Diffusivity Based on Boundary Distance** (p. 585) and **Diffusivity Based on Cell Volume** (p. 586).

5. If you want smoothing using the linearly elastic solid method (described in **Linearly Elastic Solid Based Smoothing Method** (p. 587)):
   a. Select **Linearly Elastic Solid** from the **Method** list.
   b. Enter the **Poisson’s Ratio** in the **Parameters** group box.

6. If you plan to apply the 2.5D remeshing method (as described in **2.5D Surface Remeshing Method** (p. 616)), perform the following steps to set up Laplacian smoothing (as described in **Laplacian Smoothing Method** (p. 588)).
a. Select Spring/Laplace/Boundary Layer from the Method list.

b. Define only the Laplace Node Relaxation and the Number of Iterations in the Parameters group box (the other settings are not relevant).

7. If you plan to apply the boundary layer smoothing method (as described in Boundary Layer Smoothing Method (p. 589)), select Spring/Laplace/Boundary Layer from the Method list.

10.6.2.1.1. Spring-Based Smoothing

For spring-based smoothing, the edges between any two mesh nodes are idealized as a network of interconnected springs. The initial spacings of the edges before any boundary motion constitute the equilibrium state of the mesh. A displacement at a given boundary node will generate a force proportional to the displacement along all the springs connected to the node. Using Hooke’s Law, the force on a mesh node can be written as

\[
\mathbf{F}_i = \sum_j^n k_{ij} (\Delta \mathbf{x}_j - \Delta \mathbf{x}_i) \tag{10.2}
\]

where \( \Delta \mathbf{x}_i \) and \( \Delta \mathbf{x}_j \) are the displacements of node \( i \) and its neighbor \( j \), \( n_i \) is the number of neighboring nodes connected to node \( i \), and \( k_{ij} \) is the spring constant (or stiffness) between node \( i \) and its neighbor \( j \). The spring constant for the edge connecting nodes \( i \) and \( j \) is defined as

\[
k_{ij} = \frac{k_{fac}}{\sqrt{|\mathbf{x}_i - \mathbf{x}_j|}} \tag{10.3}
\]

where \( k_{fac} \) is the value you enter for Spring Constant Factor.

At equilibrium, the net force on a node due to all the springs connected to the node must be zero. This condition results in an iterative equation such that

\[
\Delta \mathbf{x}_i^{m+1} = \frac{\sum_j^n k_{ij} \Delta \mathbf{x}_j^m}{\sum_j^n k_{ij}} \tag{10.4}
\]

where \( m \) is the iteration number.

Since displacements are known at the boundaries (after boundary node positions have been updated), Equation 10.4 (p. 578) is solved using a Jacobi sweep on all interior nodes. At convergence, the positions are updated such that

\[
\mathbf{x}_i^{n+1} = \mathbf{x}_i^n + \Delta \mathbf{x}_i^{\text{converged}} \tag{10.5}
\]

where \( n+1 \) and \( n \) are used to denote the positions at the next time step and the current time step, respectively. The spring-based smoothing is shown in Figure 10.15: Spring-Based Smoothing on Interior Nodes: Start (p. 579) and Figure 10.16: Spring-Based Smoothing on Interior Nodes: End (p. 579) for a cylindrical cell zone where one end of the cylinder is moving.
You can control the spring stiffness by adjusting the value of the **Spring Constant Factor** between 0 and 1. A value of 0 indicates that there is no damping on the springs, and boundary node displacements have more influence on the motion of the interior nodes. A value of 1 imposes the default level of damping on the interior node displacements as determined by solving **Equation 10.4** (p. 578).

The effect of the **Spring Constant Factor** is illustrated in **Figure 10.17: Interior Nodes Extend Beyond Boundary (Spring Constant Factor = 1)** (p. 580) and **Figure 10.18: Interior Nodes Remain Within Boundary (Spring Constant Factor = 0)** (p. 580), which show the trailing edge of a NACA-0012 airfoil after a counter-clockwise rotation of 2.3° and the mesh is smoothed using the spring-based smoother but limited to...
20 iterations. Degenerate cells (Figure 10.17: Interior Nodes Extend Beyond Boundary (Spring Constant Factor = 1) (p. 580)) are created with the default value of 1 for the **Spring Constant Factor**, as the interior nodes extend beyond the moving boundary. However, the original mesh distribution (Figure 10.18: Interior Nodes Remain Within Boundary (Spring Constant Factor = 0) (p. 580)) is recovered if the **Spring Constant Factor** is set to 0 (that is, no damping on the displacement of interior nodes near the airfoil surface).

**Figure 10.17: Interior Nodes Extend Beyond Boundary (Spring Constant Factor = 1)**

**Figure 10.18: Interior Nodes Remain Within Boundary (Spring Constant Factor = 0)**
You can control the solution of Equation 10.4 (p. 578) using the values of Convergence Tolerance and Number of Iterations. ANSYS Fluent solves Equation 10.4 (p. 578) iteratively during each time step until one of the following criteria is met:

- The specified number of iterations has been performed.
- The solution is converged for that time step:
  \[
  \left( \frac{\Delta x^m_{rms}}{\Delta x^{i-1}_{rms}} \right) < \text{convergence tolerance} \tag{10.6}
  \]
  where \( \Delta x^m_{rms} \) is the interior and deforming nodes RMS displacement at the first iteration.

### 10.6.2.1.1. Applicability of the Spring-Based Smoothing Method

You can use the spring-based smoothing method to update any cell or face zone whose boundary is moving or deforming.

For non-tetrahedral cell zones (non-triangular in 2D), the spring-based method can be used when the following conditions are met:

- The boundary of the cell zone moves predominantly in one direction (that is, no excessive anisotropic stretching or compression of the cell zone).
- The motion is predominantly normal to the boundary zone.

If these conditions are not met, the resulting cells may have high skewness values, since not all possible combinations of node pairs in non-tetrahedral cells (or non-triangular in 2D) are idealized as springs. Polyhedral cells are particularly likely to become highly skewed with spring-based smoothing (regardless of whether the previous conditions are met), and so the diffusion-based smoothing method is generally recommended for polyhedra (see Diffusion-Based Smoothing (p. 581)).

By default, spring-based smoothing is disabled for cell zones that are not entirely comprised of either tetrahedral or triangular cells. This is reflected in the Elements options under Parameters in the Mesh Method Settings dialog box (Figure 10.14: The Smoothing Tab of the Mesh Method Settings Dialog Box (3D) (p. 577)). By default, the Elements are set to Tet in Tet Zones in 3D (or Tri in Tri Zones in 2D). If you want to use spring-based smoothing on all element types, you can do that by selecting the All option.

If you have mixed element zones and you do not want spring-based smoothing on all element types, you can enable spring-based smoothing on only the tetrahedral or triangular cells by selecting Tet in Mixed Zones in 3D (or Tri in Mixed Zones in 2D). Selection of smoothing elements in the Mesh Method Settings dialog box applies by default to all cell zones that undergo spring-based smoothing. In order to have more precise control, it is possible to overwrite this global selection on individual dynamic cell zones (see Deforming Motion (p. 657)). This gives, for example, the flexibility to suppress smoothing in zones where dynamic layering (see Dynamic Layering (p. 592)) is used and allows at the same time smoothing of non-simplex (that is not tetrahedral or triangular) elements in other zones.

### 10.6.2.1.2. Diffusion-Based Smoothing

For diffusion-based smoothing, the mesh motion is governed by the diffusion equation
\[
\nabla \cdot ( \gamma \nabla \vec{u} ) = 0 \tag{10.7}
\]
where \( \overline{u} \) is the mesh displacement velocity. The boundary conditions for Equation 10.7 (p. 581) are obtained from the user-prescribed or computed (Six DOF) boundary motion. On deforming boundaries, the boundary conditions are such that the mesh motion is tangent to the boundary (that is, the normal velocity component vanishes). The Laplace equation Equation 10.7 (p. 581) then describes how the prescribed boundary motion diffuses into the interior of the deforming mesh.

The diffusion coefficient \( \gamma \) in Equation 10.7 (p. 581) can be used to control how the boundary motion affects the interior mesh motion. A constant coefficient means that the boundary motion diffuses uniformly throughout the mesh. With a nonuniform diffusion coefficient, mesh nodes in regions with high diffusivity tend to move together (that is, with less relative motion).

In Fluent, two different formulations are available for the diffusion coefficient \( \gamma \). The first formulation allows you to have the diffusion coefficient be a function of the boundary distance, and is of the form

\[
\gamma = \frac{1}{d^\alpha} \tag{10.8}
\]

where \( d \) is a normalized boundary distance. The second formulation allows you to have the diffusion coefficient be a function of the cell volume, and is of the form

\[
\gamma = \frac{1}{V^\alpha} \tag{10.9}
\]

where \( V \) is the normalized cell volume. In both Equation 10.8 (p. 582) and Equation 10.9 (p. 582), \( \alpha \geq 0 \) is a user input parameter. See Diffusivity Based on Boundary Distance (p. 585) and Diffusivity Based on Cell Volume (p. 586) for information about defining the diffusion coefficient.

ANSYS Fluent uses different numerical methods to solve the vector Equation 10.7 (p. 581), depending on the element types present in the mesh. In the absence of polyhedral elements or elements with hanging nodes (that is, adapted and some hexcore or CutCell meshes) the equation is solved using a finite element discretization and the displacement velocity, \( \overline{u} \), is obtained directly at each mesh node. If the mesh contains polyhedral elements or hanging nodes, the equation is discretized using ANSYS Fluent’s standard finite volume method and the cell-centered solution for the displacement velocity, \( \overline{u} \), is interpolated onto the nodes using inverse-distance-weighted averaging. The node positions are then updated according to:

\[
\overline{x}_{\text{new}} = \overline{x}_{\text{old}} + \overline{u} \Delta t \tag{10.10}
\]

The finite element discretization is generally superior, as the solution is obtained directly at the nodes and no interpolation step is necessary. The finite volume method can be enforced for meshes of all element types by executing the TUI command:

```
/define/dynamic-mesh/controls/smoothing-parameters/diffusion-fvm? yes
```

Computationally, solving a PDE for mesh smoothing is generally more costly than spring-based smoothing. But it tends to produce better quality meshes than spring-based smoothing and often allows larger boundary deformations before breaking down. Figure 10.19: The Initial Mesh (p. 583) and Figure 10.20: Valid Mesh After 45 Degree Rotation Using Diffusion-Based Smoothing (p. 583) show a mesh before and after rotating the boundary by 45 degrees, using diffusion-based smoothing. With spring-based smoothing, the same mesh shows degenerated cells after a rotation of 40 degrees (Figure 10.21: Degenerated Mesh After 40 Degree Rotation Using Spring-Based Smoothing (p. 584)).
Figure 10.19: The Initial Mesh

Figure 10.20: Valid Mesh After 45 Degree Rotation Using Diffusion-Based Smoothing
It should be noted that with diffusion-based smoothing the interior mesh motion is governed by the solution to Equation 10.7 (p. 581) and the prescribed boundary motion, and not by mesh irregularities. Poor quality elements or mesh defects are not smoothed out by this method, but rather move together with the pre-computed (at the begin of each mesh update) displacement velocity \( \bar{\vec{u}} \).

It is also worth noting that the nature of the diffusion equation is such that the resulting solution (that is, the displacement velocity \( \bar{\vec{u}} \)) depends on the dimensionality of the problem and the type of boundary motion prescribed. To illustrate the impact of the type of boundary motion, consider the goal of boundary-distance-based diffusion (Equation 10.8 (p. 582)): to control which parts of the mesh absorb the boundary motion, so that you can preserve the mesh in the vicinity of the moving boundary (at the expense of the interior of the mesh). For more translational (piston-type) boundary motions, you can preserve a reasonably “thick” region of the mesh adjacent to the boundary (that is, multiple layers of cells); for rotational boundary motions, the rate of decay for the solution as you move away from the boundary is such that it can be difficult to preserve even a “thin” region. For this reason, mesh smoothing can handle translational boundary motions generally much better than rotational motions.

Although it should in most cases not be necessary, the accuracy of the solution to the diffusion equation governing the mesh motion can be controlled by selecting the maximum number of iterations, \( \text{max-iter} \), and the relative residual tolerance, \( \text{relative-convergence-tolerance} \), in the text interface:

```
define \rightarrow \text{dynamic-mesh} \rightarrow \text{controls} \rightarrow \text{smoothing-parameters} \rightarrow \text{max-iter}
```

```
define \rightarrow \text{dynamic-mesh} \rightarrow \text{controls} \rightarrow \text{smoothing-parameters} \rightarrow \text{relative-convergence-tolerance}
```

You can enable printing of smoothing residuals in the text interface with the command:

```
/define/dynamic-mesh/controls/smoothing-parameters/verbosity 1
```
10.6.2.1.2.1. Diffusivity Based on Boundary Distance

Using boundary-distance-based diffusion (Equation 10.8 (p. 582)) allows you to control how the boundary motion diffuses into the interior of the domain as a function of boundary distance. Decreasing the diffusivity away from the moving boundary causes those regions to absorb more of the mesh motion, and better preserves the mesh quality near the moving boundary. This is particularly helpful for a moving boundary that has pronounced geometrical features (such as sharp corners) along with a prescribed motion that is predominantly rotational.

You can manipulate the diffusion coefficient $\gamma$ (in Equation 10.8 (p. 582)) primarily by adjusting the Diffusion Parameter $\alpha$. A range of 0 to 2 has been shown to be of practical use. A value of 0 (the default value) specifies that $\gamma = 1$ and yields a uniform diffusion of the boundary motion throughout the mesh. Higher values of $\alpha$ preserve larger regions of the mesh near the moving boundary, and cause the regions away from the moving boundary to absorb more of the motion.

The following two figures illustrate the effect of the Diffusion Parameter $\alpha$ on the resulting mesh for a translational (piston-type) boundary motion, when the diffusivity is based on the boundary distance. In this example, an initially uniformly meshed square domain is deformed by moving the left boundary to the right.

Figure 10.22: Effect of Diffusion Parameter of 0 on Interior Node Motion
Figure 10.23: Effect of Diffusion Parameter of 1 on Interior Node Motion

For rotational boundary motions, a value of 1.5 for the Diffusion Parameter $\alpha$ is recommended as a good starting point.

Two different methods are available for the evaluation of the boundary distance $d$ if boundary-distance-based diffusion is used. By default, Fluent uses the “standard” boundary distance in Equation 10.8 (p. 582), which is the normalized distance to the nearest wall boundary; note that none of the other boundary types (for example, inlets, outlets, symmetry, and periodic boundaries) are considered. This method is the same as that which is used to evaluate the boundary distance for turbulence models. An example of this method is shown in Figure 10.23: Effect of Diffusion Parameter of 1 on Interior Node Motion (p. 586), where only the left and right boundaries are walls. You have the option of using a “generalized” boundary distance instead, which is the normalized distance to the nearest boundary that is not declared as deforming, regardless of type. Both methods use the largest distance found in all deforming cell zones to normalize the value.

You can specify that the generalized boundary distance is used via the following text command:

```
define → dynamic-mesh → controls → smoothing-parameters → boundary-distance-method
```

If the generalized boundary distance is used, an additional scalar equation for the boundary distance $d$ will be solved as part of the solution of Equation 10.7 (p. 581).

### 10.6.2.1.2.2. Diffusivity Based on Cell Volume

Using cell-volume-based diffusion (Equation 10.9 (p. 582)) allows you to control how the boundary motion diffuses into the interior of the domain as a function of cell size. Decreasing the diffusivity in larger cells...
causes those cells to absorb more of mesh motion and therefore better preserves the cell quality of smaller cells.

You can manipulate the diffusion coefficient \( \gamma \) (in Equation 10.8 (p. 582)) by adjusting the **Diffusion Parameter** \( \alpha \). A value of 0 (the default value) specifies that \( \gamma = 1 \) and yields a uniform diffusion of the boundary motion throughout the mesh. Higher values of \( \alpha \) result in larger cells absorbing more of the motion than smaller cells.

Note that the cell volume used in Equation 10.9 (p. 582) is the local cell volume, normalized by the average cell volume of all deforming cell zones.

### 10.6.2.1.2.3. Applicability of the Diffusion-Based Smoothing Method

Diffusion-based mesh smoothing is an alternative method to spring-based smoothing. It is available for all element types, and you can use it to update any cell zone whose boundaries are moving or deforming.

Diffusion-based smoothing is computationally more expensive than spring-based smoothing, but likely results in better mesh quality (especially for non-tetrahedral / non-triangular cell zones, and for polyhedral cells in particular) and generally allows for larger boundary deformations before breaking down.

Similar to spring-based smoothing, diffusion-based mesh smoothing can handle translational boundary deformations much better than rotational motions.

Diffusion-based smoothing is not compatible with the boundary layer smoothing method or the face region remeshing method. For more information about these methods, see [Boundary Layer Smoothing Method (p. 589)](BoundaryLayerSmoothingMethod) and [Face Region Remeshing Method (p. 608)](FaceRegionRemeshingMethod).

### 10.6.2.1.3. Linearly Elastic Solid Based Smoothing Method

With mesh smoothing based on the linearly elastic solid model, the mesh motion is governed by the following set of equations.

\[
\begin{align*}
\nabla \cdot \sigma(\vec{y}) &= 0 \\
\sigma(\vec{y}) &= \lambda \left( \text{tr}(\varepsilon(\vec{y})) \right) I + 2\mu \varepsilon(\vec{y}) \\
\varepsilon(\vec{y}) &= \frac{1}{2} \left( \nabla \vec{y} + (\nabla \vec{y})^T \right)
\end{align*}
\]

where \( \sigma \) is the stress tensor, \( \varepsilon \) is the strain tensor, and \( \vec{y} \) is the mesh displacement. For the solution of Equation 10.11 (p. 587) only the ratio between the shear modulus, \( \mu \), and Lamé's first parameter, \( \lambda \), matters. This ratio is parameterized through Poisson's ratio:

\[
\nu = \frac{1}{2 \left( 1 + \frac{\mu}{\lambda} \right)}
\]

which is made available as a user input.

The boundary conditions for Equation 10.11 (p. 587) are obtained from the user-prescribed or computed (in the case of 6 DOF motion) boundary deformations. These imposed deformations are transferred into the interior of the deforming mesh as if the mesh was a linearly elastic solid with the given material properties. On deforming boundaries you can either specify a geometry along which the mesh can slide, or leave the geometry unspecified. If a geometry is specified for the deforming boundary, then the boundary conditions are such that the deformation normal to the boundary vanishes and the stress tangential to the boundary is zero. If the geometry of the deforming boundary is unspecified, then the
deforming boundary can also deform in the normal direction and the boundary conditions are such that the traction is zero in all directions. See Deforming Motion (p. 657) for details of how to specify geometry on deforming zones.

The linear system in Equation 10.11 (p. 587) is solved using a finite element discretization and the mesh displacements for the interior and deforming boundary nodes are obtained directly at the nodes. The accuracy to which the linear system is solved can be controlled by the maximum number of iterations max-iter, and the relative residual tolerance relative-convergence-tolerance in the text interface:

```
define → dynamic-mesh → controls → smoothing-parameters → max-iter
```

```
define → dynamic-mesh → controls → smoothing-parameters → relative-convergence-tolerance
```

The linearly elastic solid mesh smoothing model supports constant material properties only. The permissible range for Poisson's ratio, \( \nu \), is between -1.0 and 0.5.

### 10.6.2.1.3.1. Applicability of the Linearly Elastic Solid Based Smoothing Method

Mesh smoothing based on the linearly elastic solid model is an alternative method to diffusion-based and spring-based smoothing. Most of the properties and limitations discussed for diffusion-based smoothing (Applicability of the Diffusion-Based Smoothing Method (p. 587)) also apply to the linearly elastic solid model, particularly the mesh quality degradation for rotational motions. The linearly elastic solid model is computationally more expensive than diffusion-based smoothing, but for some meshes and mesh motions preserves the mesh quality better.

The current implementation with constant material properties can be a limitation compared with diffusion-based smoothing with non-uniform diffusivity. In cases with rotational boundary motion and sharp corners it may be advantageous to use diffusion-based smoothing with boundary-distance-dependent diffusivity.

The option to leave the geometry of deforming face zones unspecified is only available with the linearly elastic solid smoothing method.

The linearly elastic solid smoothing method supports triangular and quadrilateral elements in 2D and tetrahedral, hexahedral, wedge, and pyramid cells in 3D. It cannot be applied if the deforming cell zone contains polyhedral cells or hanging nodes. In such cases diffusion-based smoothing is recommended.

Linearly elastic solid smoothing is not compatible with the boundary layer smoothing method or the face region remeshing method. For more information about these methods, see Boundary Layer Smoothing Method (p. 589) and Face Region Remeshing Method (p. 608).

### 10.6.2.1.4. Laplacian Smoothing Method

Laplacian smoothing is the most commonly used and the simplest mesh smoothing method. This method adjusts the location of each mesh vertex to the geometric center of its neighboring vertices. This method is computationally inexpensive but it does not guarantee an improvement on mesh quality, since repositioning a vertex by Laplacian smoothing can result in poor quality elements. To overcome this problem, ANSYS Fluent only relocates the vertex to the geometric center of its neighboring vertices if and only if there is an improvement in the mesh quality (that is, the skewness has been improved).
This improved Laplacian smoothing can be enabled on deforming boundaries only (that is, the zone with triangular elements in 3D and zones with linear elements in 2D). The computation of the node positions works as follows:

\[
\overline{x}_i^m = \sum_{j=1}^{n_i} \frac{x_j^m}{n_i}
\]  

(10.13)

where \(\overline{x}_i^m\) is the averaged node position of node \(i\) at iteration \(m\), \(x_j^m\) is the node position of neighbor node of \(\overline{x}_i^m\) at iteration \(m\), and \(n_i\) is the number nodes neighboring node \(i\). The new node position \(x_i^{m+1}\) is then computed as follows:

\[
x_i^{m+1} = x_i^m (1 - \beta) + \overline{x}_i^m \beta
\]  

(10.14)

where \(\beta\) is the Laplace node relaxation factor.

This update only happens if the maximum skewness of all faces adjacent to \(x_i^{m+1}\) is improved in comparison to \(x_i^m\).

For details on applying Laplacian smoothing to either a cell zone (with 2.5D remeshing) or a face zone, see Smoothing Methods (p. 576) or Deforming Motion (p. 657), respectively.

### 10.6.2.1.5. Boundary Layer Smoothing Method

The boundary layer smoothing method is used to deform the boundary layer mesh during a moving-deforming mesh simulation. For cases that apply mesh motion (either Rigid Body or User-Defined) to a face zone with adjacent boundary layers, the boundary layers can be made to deform accordingly by enabling Deform Adjacent Boundary Layer with Zone for the face zone in the Dynamic Mesh Zones Dialog Box (p. 2190). With boundary layer smoothing enabled, the nodal coordinates of each cell in the boundary layer zone are updated with the same displacement vector as the corresponding nodes on the underlying face zone. The boundary layer smoothing method can be applied to boundary layer zones of all mesh types (that is, wedges and hexahedra in 3D, quadrilaterals in 2D).

Consider the example below, where a UDF of the form DEFINE_GRID_MOTION provides the moving-deforming mesh model with the locations of the nodes located on the compliant strip on an idealized airfoil. The node motion varies sinusoidally in time and space (compare Figure 10.24: The Undeformed Mesh (p. 590) with Figure 10.25: The Deformed Mesh (p. 590)).
Figure 10.24: The Undeformed Mesh

Figure 10.25: The Deformed Mesh
As a result of the boundary layer smoothing, the cells adjacent to the deforming wall are also deformed in order to preserve the quality of boundary layer zone. If you compare Figure 10.26: Zooming into the Undeformed Compliant Strip (p. 591) with Figure 10.27: Zooming into the Deformed Compliant Strip with Boundary Layer Smoothing Applied (p. 592), you can see how the boundary layer cells have been deformed according to the motion of the nodes on the compliant strip.

**Figure 10.26: Zooming into the Undeformed Compliant Strip**
Typically, the boundary layer smoothing method preserves the height of the boundary layer cells adjacent to the deformed face zone. However, note that this approach is primarily intended for translational motion. If the faces undergo substantial rotation, the boundary layer cells may become skewed. See Smoothing Methods (p. 576) and Specifying Boundary Layer Deformation Smoothing (p. 662) for details about enabling smoothing and defining a moving and deforming boundary layer, respectively. Note that boundary layer smoothing is compatible with spring-based smoothing only. It cannot be used with diffusion-based smoothing or linearly elastic solid smoothing. Also note that the boundary layer smoothing method will work whether or not you have segregated the boundary layer elements into a separate cell zone.

### 10.6.2.2. Dynamic Layering

In prismatic (hexahedral and/or wedge) mesh zones, you can use dynamic layering to add or remove layers of cells adjacent to a moving boundary, based on the height of the layer adjacent to the moving surface. The dynamic mesh model in ANSYS Fluent allows you to specify an ideal layer height on each moving boundary. The layer of cells adjacent to the moving boundary (layer $j$ in Figure 10.28: Dynamic Layering (p. 593)) is split or merged with the layer of cells next to it (layer $i$ in Figure 10.28: Dynamic Layering (p. 593)) based on the height ($h$) of the cells in layer $j$. 

![Figure 10.27: Zooming into the Deformed Compliant Strip with Boundary Layer Smoothing Applied](image-url)
If the cells in layer \( j \) are expanding, the cell heights are allowed to increase until
\[
h_{\text{min}} > (1 + \alpha_s) h_{\text{ideal}}
\]
where \( h_{\text{min}} \) is the minimum cell height of cell layer \( j \), \( h_{\text{ideal}} \) is the ideal cell height, and \( \alpha_s \) is the layer split factor. Note that ANSYS Fluent allows you to define \( h_{\text{ideal}} \) as either a constant value or a value that varies as a function of time or crank angle. When the condition in Equation 10.15 (p. 593) is met, the cells are split based on the specified layering option. This option can be height based or ratio based.

With the height-based option, the cells are split to create a layer of cells with constant height \( h_{\text{ideal}} \) and a layer of cells of height \( h - h_{\text{ideal}} \). With the ratio-based option the cells are split such that, locally, the ratio of the new cell heights to old cell heights is exactly \( \alpha_s \) everywhere. Figure 10.29: Results of Splitting Layer with the Height-Based Option (p. 593) and Figure 10.30: Results of Splitting Layer with the Ratio-Based Option (p. 594) show the result of splitting a layer of cells above a valve geometry using the height-based and ratio-based option.
If the cells in layer $j$ are being compressed, they can be compressed until

$$h_{min} < \alpha_c h_{ideal}$$  \hspace{1cm} (10.16)

where $\alpha_c$ is the layer collapse factor. When this condition is met, the compressed layer of cells is merged into the layer of cells above the compressed layer in Figure 10.28: Dynamic Layering (p. 593); that is, the cells in layer $j$ are merged with those in layer $i$.

To enable dynamic layering, enable the **Layering** option under **Mesh Methods** in the Dynamic Mesh Task Page (p. 2175) (Figure 10.31: The Layering Tab in the Mesh Method Settings Dialog Box (p. 595)). The layering control is specified in the **Layering** tab, which can be displayed by clicking **Settings**.
You can control how a cell layer is split by specifying either **Height Based** or **Ratio Based** under **Options**. Note that for **Height Based**, the height of the cells in a particular new layer will be constant, but you can choose to have this height vary from layer to layer as a function of time or crank angle when you specify the **Cell Height** in the **Dynamic Mesh Zones** dialog box (see [Specifying the Motion of Dynamic Zones](p. 650) for further details).

The **Split Factor** and **Collapse Factor** (\(\alpha_s\) in [Equation 10.15](p. 593) and \(\alpha_c\) in [Equation 10.16](p. 594), respectively) are the factors that determine when a layer of cells (hexahedra or wedges in 3D, or quadrilaterals in 2D) that is next to a moving boundary is split or merged with the adjacent cell layer, respectively.

### 10.6.2.2.1. Applicability of the Dynamic Layering Method

You can use the dynamic layering method to split or merge cells adjacent to any moving boundary provided the following conditions are met:

- All cells adjacent to the moving face zone are either wedges or hexahedra (quadrilaterals in 2D) even though the cell zone may contain mixed cell shapes.

- The cell layers must be completely bounded by one-sided face zones, except when sliding interfaces are used (see [Applicability of the Face Region Remeshing Method](p. 611)).
• If the bounding face zones are two-sided walls, you must split the wall and wall-shadow pair and use the coupled sliding interface option to couple the two adjacent cell zones.

• Note that you cannot use the dynamic layering method in conjunction with hanging node adaption. For more information on hanging node adaption, see **Hanging Node Adaption** in the Theory Guide.

If the moving boundary is an internal zone, cells on both sides (possibly with different ideal cell layer heights) of the internal zone are considered for dynamic layering.

If you want to use dynamic layering on cells adjacent to a moving wall that do not span from boundary to boundary, you must separate those cells that are involved in the dynamic layering and use the sliding interfaces capability in ANSYS Fluent to transition from the deforming cells to the adjacent non-deforming cells (see **Figure 10.32: Use of Sliding Interfaces to Transition Between Adjacent Cell Zones and the Dynamic Layering Cell Zone** (p. 596)). For a moving interior face, the zones must be separated such that they are either expanding or collapsing on the same side. No one zone can consist of both expanding and collapsing layers.

**Figure 10.32: Use of Sliding Interfaces to Transition Between Adjacent Cell Zones and the Dynamic Layering Cell Zone**

10.6.2.3. Remeshing Methods

On zones with a triangular or tetrahedral mesh, the spring-based smoothing method (described in **Spring-Based Smoothing** (p. 578)) is normally used. When the boundary displacement is large compared to the local cell sizes, the cell quality can deteriorate or the cells can become degenerate. This will invalidate the mesh (for example, result in negative cell volumes) and consequently, will lead to convergence problems when the solution is updated to the next time step.

To circumvent this problem, ANSYS Fluent agglomerates cells that violate the skewness or size criteria and locally remeshes the agglomerated cells or faces. If the new cells or faces satisfy the skewness criterion, the mesh is locally updated with the new cells (with the solution interpolated from the old cells). Otherwise, the new cells are discarded and the old cells are retained.
ANSYS Fluent includes several remeshing methods that include local cell remeshing, zone remeshing, local face remeshing (for 3D flows only), face region remeshing, CutCell zone remeshing (for 3D flows only), and 2.5D surface remeshing (for 3D flows only). The remeshing methods are suitable for particular kinds of cell types:

- The local cell remeshing method only affects triangular and tetrahedral cell types in the mesh (that is, in mixed cell zones the non-triangular/tetrahedral cells are skipped).

- The local face remeshing method is available in 3D only and can remesh tetrahedral cells and wedge cells in boundary layer meshes.

- The zone remeshing method replaces all cell types with triangular tetrahedral cells (in 2D and 3D domains, respectively), and can remesh and produce wedge cells in 3D boundary layer meshes.

- The face region remeshing method is applied to triangular cells in 2D, and tetrahedral cells in 3D. In 3D domains, the face region remeshing method can also remesh and produce wedge cells in 3D boundary layer meshes.

- The CutCell zone remeshing method works for all cell types.

- The 2.5D remeshing method only works on hexagonal meshes or wedge cells extruded from triangular surface elements.

To enable remeshing methods, enable the **Remeshing** option under **Mesh Methods** in the Dynamic Mesh Task Page (p. 2175) (Figure 10.13: The Dynamic Mesh Task Page(p. 575)). Click the **Settings...** button to open the **Mesh Method Settings** dialog box, where you can specify the remeshing method and parameters in the **Remeshing** tab (Figure 10.33: The Remeshing Tab in the Mesh Method Settings Dialog Box (p. 598)).

You can view the vital statistics of your mesh by clicking the **Mesh Scale Info...** button at the bottom of the **Mesh Method Settings Dialog Box** (p. 2177). This dialog box displays the **Mesh Scale Info Dialog Box** (p. 2180) where you can view the minimum and maximum length scale values as well as the maximum cell and face skewness values.
Figure 10.33: The Remeshing Tab in the Mesh Method Settings Dialog Box
10.6.2.3.1. Local Remeshing Method

Using the local remeshing method (that is, local cell remeshing, with or without local face remeshing), ANSYS Fluent marks cells based on cell skewness and minimum and maximum length scales as well as an optional sizing function.

ANSYS Fluent evaluates each cell and marks it for remeshing if it meets one or more of the following criteria:

- It has a skewness that is greater than a specified maximum skewness.
- It is smaller than a specified minimum length scale.
- It is larger than a specified maximum length scale.
- Its height does not meet the specified length scale (at moving face zones, for example, above a moving piston).

If local remeshing is not able to reduce the maximum cell skewness sufficiently, then the cell zone remeshing method is used to automatically remesh all of the cells in the cell zone, as well as the faces of all adjacent deforming dynamic face zones (see Cell Zone Remeshing Method (p. 607) for details).
maximum allowable cell skewness is set to be 0.98 by default. The cell zone remeshing method gives
the meshers more flexibility to create a new mesh of better quality than the local cell remeshing method.
The automatic remeshing of cell zones can be disabled using the following text command:

`define → dynamic-mesh → controls → remeshing-parameter → zone-remeshing`

### 10.6.2.3.1.1. Local Cell Remeshing Method

As previously mentioned, in local cell remeshing, ANSYS Fluent agglomerates cells based on skewness,
size, and height (adjacent moving face zones) prior to the movement of the boundary. The size criteria
are specified with `Minimum Length Scale` and `Maximum Length Scale`. Cells with length scales below
the minimum length scale and above the maximum length scale are marked for remeshing. The value
of `Maximum Cell Skewness` indicates the desired skewness of the mesh. By default, the `Maximum
Cell Skewness` is set to 0.9 for 3D simulations and 0.7 for 2D simulations. Cells with skewness above
the maximum skewness are marked for remeshing.

The marking of cells based on skewness is done at every time step when the local remeshing method
is enabled. However, marking based on size and height is performed between the specified `Size
Remeshing Interval` since the change in cell size distribution is typically small over one time step.

By default, ANSYS Fluent replaces the agglomerated cells only if the quality of the remeshed cells has
improved.

### 10.6.2.3.1.2. Local Face Remeshing Method

The local face remeshing method only applies to 3D geometries. Using this method, ANSYS Fluent marks
the faces (and the adjacent cells) on the deforming boundaries based on the face skewness. This
method allows you to remesh locally at deforming boundaries.

Local face remeshing also allows the remeshing of wedge cells in boundary layers at deforming
boundaries. The detection of boundary layers (as well as the wedge element height distribution and
number of layers) is automatic and does not require your input.

Enable the `Local Face` remeshing option and set the `Maximum Face Skewness` to a specific value. In
addition, you should enable the `Remeshing` option in the `Meshing Options` tab of the `Dynamic Mesh
Zones Dialog Box` (p. 2190) for a deforming zone type (see `Deforming Motion` (p. 657)).

### 10.6.2.3.1.2.1. Applicability of the Local Face Remeshing Method

If you define deforming face zones in your model and enable local face remeshing, then the faces of
the deforming face zone can be remeshed only if the following conditions are met:

- The faces are triangular.
- The agglomerated faces do not span multiple zones or feature edges.
- Note that you cannot use the local face remeshing method in conjunction with hanging node adaption.
  For more information on hanging node adaption, see `Hanging Node Adaption` in the `Theory Guide`.

### 10.6.2.3.1.3. Local Remeshing Based on Size Functions

Instead of marking cells based on minimum and maximum length scales, ANSYS Fluent also marks cells
based on the size distribution generated by the sizing function if the `Sizing Function` option is enabled.

Cells can be marked using size functions only with the following remeshing methods:
• local cell remeshing

• 2.5D surface remeshing (as described in 2.5D Surface Remeshing Method (p. 616))

Figure 10.36: Mesh at the End of a Dynamic Mesh Simulation With Size Functions (p. 602) demonstrates the advantages of using size functions for local remeshing.

Figure 10.35: Mesh at the End of a Dynamic Mesh Simulation Without Size Functions
In determining the sizing function, ANSYS Fluent draws a bounding box around the zone that is approximately twice the size of the zone, and locates the shortest feature length within each fluid zone. ANSYS Fluent then subdivides the bounding box based on the shortest feature length and the **Size Function Resolution** that you specify. This allows ANSYS Fluent to create a background mesh.

You control the resolution of the background mesh and a background mesh is created for each fluid zone. The shortest feature length is determined by shrinking a second box around the object, and then selecting the shortest edge on that box. The size function is evaluated at the vertex of each individual background mesh.
As seen in Figure 10.37: Size Function Determination at Background Mesh Vertex I (p. 603), the local value of the size function $SF_1$ is defined by

$$SF_1 = \left( \frac{\Sigma \frac{1}{D_j} \Delta s_j}{\Sigma \frac{1}{D_j}} \right)$$

(10.17)

where $D_j$ is the distance from vertex $j$ on the background mesh to the centroid of boundary cell $J$ and $\Delta s_j$ is the mesh size (length) of boundary cell $J$.

The size function is then smoothed using Laplacian smoothing. ANSYS Fluent then interpolates the value of the size function by calculating the distance $L_I$ from a given cell centroid $P$ to the background mesh vertices that surround the cell (see Figure 10.38: Interpolating the Value of the Size Function (p. 604)). The intermediate value of the size function $size_b$ at the centroid is computed from

$$size_b = \left( \frac{\Sigma SF_I \frac{1}{L_I}}{\Sigma \frac{1}{L_I}} \right)$$

(10.18)
Next, a single point $Q$ is located within the domain (see Figure 10.39: Determining the Normalized Distance (p. 605)) that has the largest distance $d_{max}$ to the nearest boundary to it. The normalized distance $d_b$ for the given centroid $P$ is given by

$$d_b = \frac{d_{min}}{d_{max}}$$

(10.19)
Using the parameters $\alpha$ and $\beta$ (the **Size Function Variation** and the **Size Function Rate**, respectively), you can write the final value $size_P$ of the size function at point $P$ as

$$size_P = size_b \times \left(1 + \alpha \times \frac{1 + 2\beta}{d_b^1}\right) = size_b \times \gamma$$  \hspace{1cm} (10.20)

where $size_b$ is the intermediate value of the size function at the cell centroid.

Note that $\alpha$ is the size function variation. Positive values mean that the cell size increases as you move away from the boundary. Since the maximum value of $d_b$ is one, the maximum cell size becomes

$$size_{P, \text{max}} = size_b \times (1 + \alpha) = size_b \times \gamma_{\text{max}}$$  \hspace{1cm} (10.21)

therefore, $\alpha$ is really a measure of the maximum cell size.

The factor $\gamma$ is computed from

$$\gamma = 1 + \alpha d_b^{1 + 2\beta} \quad \text{if} \quad \alpha > 0$$  \hspace{1cm} (10.22)

$$\gamma = 1 + \alpha d_b^{1 - \beta} \quad \text{if} \quad \alpha < 0$$  \hspace{1cm} (10.23)

You can use **Size Function Variation** (or $\alpha$) to control how large or small an interior cell can be with respect to its closest boundary cell. $\alpha$ ranges from $-1$ to $\infty$; an $\alpha$ value of 0.5 indicates that the interior cell size can be, at most, 1.5 the size of the closest boundary cell. Conversely, an $\alpha$ value of $-0.5$ indicates that the cell size interior of the boundary can be half of that at the closest boundary cell. A value of 0 indicates a constant size distribution away from the boundary.

You can use **Size Function Rate** (or $\beta$) to control how rapidly the cell size varies from the boundary. The value of $\beta$ should be specified such that $-0.99 < \beta < +0.99$. A positive value indicates a slower
transition from the boundary to the specified Size Function Variation value. Conversely, a negative value indicates a faster transition from the boundary to the Size Function Variation value. A value of 0 indicates a linear variation of cell size away from the boundary.

You can also control the resolution of the sizing function with Size Function Resolution. The resolution determines the size of the background bins used to evaluate the size distribution with respect to the shortest feature length of the current mesh. By default, the Size Function Resolution is 3 in 2D problems, and 1 in 3D problems.

A set of default values (based on the current mesh) is automatically generated if you click Use Defaults.

In summary, the sizing function is a distance-weighted average of all mesh sizes on all boundary faces (both stationary and moving boundaries). The sizing function is based on the sizes of the boundary cells, with the size computed from the cell volume by assuming a perfect (equilateral) triangle in 2D and a perfect tetrahedron in 3D. You can control the size distribution by specifying the Size Function Variation and the Size Function Rate. If you have enabled the Sizing Function option, ANSYS Fluent will agglomerate a cell if

\[
\text{size} \notin \left[\frac{4}{5}\gamma size_b, \frac{5}{4}\gamma size_b\right]
\]  \hspace{1cm} (10.24)

where \( \gamma \) is a factor defined by Equation 10.22 (p. 605) and Equation 10.23 (p. 605).

Note that the size function is only used for marking cells before remeshing. The size function is not used to govern the size of the cell during remeshing.

For steady-state applications (see Steady-State Dynamic Mesh Applications (p. 669)), you can instruct ANSYS Fluent to perform a second round of cell marking and agglomeration after the boundary has moved, based on skewness criteria. The intent is to further improve the mesh quality through additional local remeshing. This optional feature works in conjunction with the Dynamic Mesh Task Page (p. 2175) (Figure 10.33: The Remeshing Tab in the Mesh Method Settings Dialog Box (p. 598)), and operates according to the skewness parameters you set in this dialog box. The size function parameters are not considered during this additional remeshing. Note that enabling this option will increase the time required to update the mesh during the solution.

**Important**

Additional local remeshing after the boundary has moved is not available for transient dynamic mesh applications, as the resulting numerical method would no longer be conservative.

When you use the Sizing Function remeshing option (see Figure 10.34: The Remeshing Tab in the Mesh Method Settings Dialog Box Using the Sizing Function Option (p. 599)), you can control three parameters that govern the size function. You can specify the Size Function Resolution, the Size Function Variation, and the Size Function Rate or you can return to ANSYS Fluent's default values by using the Use Defaults button.

The size function Resolution controls the density of the background mesh (see Local Remeshing Based on Size Functions (p. 600)). By default, it is equivalent to 3 in 2D simulations and 1 in 3D simulations.

The size function Variation corresponds to \( \alpha \) in Equation 10.20 (p. 605). It is the measure of the maximum permissible cell size and it ranges from \(-1 < \alpha < +\infty\).
The size function **Rate** corresponds to $\beta$ in Equation 10.20 (p. 605). It is the measure of the rate of growth of the cell size, and it ranges from $-0.99 < \beta < 0.99$. A value of 0 implies linear growth, whereas higher values imply a slower growth near the boundary with faster growth as one moves toward the interior.

**Note**

To employ additional local remeshing, first make sure that you have enabled the **Remeshing** option in the Dynamic Mesh Task Page (p. 2175).

You can also use the following text command:

```define ➔ dynamic-mesh ➔ controls ➔ remeshing-parameter ➔ remeshing-after-moving?```

Finally, type **yes** to the question, **optional remeshing after moving the mesh?**

### 10.6.2.3.2. Cell Zone Remeshing Method

The cell zone remeshing method allows for the remeshing of the complete cell zone, and provides the option to also remesh the faces of all adjacent deforming dynamic face zones. This remeshing method is enabled by default when local cell remeshing is enabled, and is performed automatically if the local cell remeshing does not produce an acceptable mesh (see **Local Remeshing Method** (p. 599) for the acceptability criteria). Cell zone remeshing can also be manually invoked, using the following text command:

```define ➔ dynamic-mesh ➔ actions ➔ remesh-cell-zone```

The cell zone remeshing method is available for triangular cells in 2D meshes and tetrahedral cells in 3D meshes. For 3D meshes, the method also allows the remeshing of wedge cells in boundary layers. The detection of the boundary layers (as well as the wedge element height distribution and number of layers) is automatically performed by default, and allows for different layer parameters on each boundary zone. You can manually specify the parameters by entering non-zero values for first height, growth rate, and number of layers via the text commands available in the `define/dynamic-mesh/controls/remeshing-parameters/prism-layer-parameters` menu, although generally it is not necessary to do this. When you enter them manually, the boundary layer parameters are global: they apply to every prism layer detected in the remeshing zone.

Note that it is necessary to enable the dynamic mesh model and the remeshing method in order to attain access to the prism layer controls, even if the cell zone is remeshed manually and not as part of a dynamic mesh update.

### 10.6.2.3.2.1. Limitations of the Cell Zone Remeshing Method

Zone remeshing has the following limitations:

- Only triangular, tetrahedral, and wedge cell types (when the wedge cells are part of a 3D boundary layer mesh) are remeshed.
- Zones with hanging nodes cannot be remeshed.
- In parallel, the zone remeshing will automatically migrate all elements to be remeshed to a single CPU. Consequently, the machine memory will limit the size of the zone that can be remeshed.
10.6.2.3.3. Face Region Remeshing Method

The face region remeshing method allows for the remeshing of those triangular faces (in 3D meshes) and linear faces (in 2D meshes) that are on a deforming face zone and adjacent to a moving face zone (see layer j in Figure 10.40: Expanding Cylinder Before Region Face Remeshing (p. 608)). ANSYS Fluent marks the faces based on minimum and maximum length scales, and then remeshes the faces and the associated cells to produce a very regular mesh on the deforming boundary. Although primarily designed for in-cylinder type configurations, where the remeshing region is located where cylinder walls meet the moving piston, face region remeshing can be used for all applications where a moving dynamic zone abuts deforming dynamic face zones.

For 3D simulations, ANSYS Fluent allows face region remeshing with symmetric boundary conditions and across multiple face zones. The remeshing can preserve features not only between the different deforming face zones, but also within a face zone. For more information on feature preservation, see Feature Detection (p. 619). ANSYS Fluent also allows face region remeshing of tetrahedral cell zones that contain wedge cells in boundary layers, as described in the section that follows.

To begin marking the faces for face region remeshing, ANSYS Fluent identifies the nodes at the intersection of a moving dynamic zone and the adjacent deforming zones. ANSYS Fluent then analyzes the height of the faces on the deforming zones that are in the range of the identified nodes, and then remeshes the faces depending on the specified maximum or minimum length scale.

Consider the simple tetrahedral mesh of a cylinder that has a moving end wall (see Figure 10.40: Expanding Cylinder Before Region Face Remeshing (p. 608)). The faces that are subject to remeshing are in layer j of the side wall. If the faces in layer j are expanding, the expansion continues until the height \( h \) reaches the maximum length scale, and then the layer is remeshed to form 2 layers of elements (see Figure 10.41: Expanding Cylinder After Region Face Remeshing (p. 609)). Conversely, if the faces of layer j are contracting, the contraction continues until \( h \) reaches the minimum length scale, and then layer j and the neighboring layer of faces (layer i) on the deforming zone are remeshed to form a single layer.

**Figure 10.40: Expanding Cylinder Before Region Face Remeshing**

![Figure 10.40: Expanding Cylinder Before Region Face Remeshing](image-url)
10.6.2.3.3.1. Face Region Remeshing with Wedge Cells in Prism Layers

In 3D simulations, the face region remeshing method can be applied on meshes that have wedge cells along the deforming face zones. When remeshing the faces on the deforming face zones, the associated wedge cells are remeshed as well. The layer parameters are based on the existing mesh by default; you have the option of manually setting these parameters, as described later in this section.

If the motion of the face zone is large compared to the height of the adjacent deforming face zones, it is recommended that you decompose the mesh volume in such a way as to create a dynamic cell zone that moves as a rigid body in between the moving face zone and the deforming dynamic cell zone on which face region remeshing is applied. Consider Figure 10.42: Volume Decomposition for Prism Layers (p. 610), which displays only half of an in-cylinder mesh. The rigidly moving cell zone encapsulates the prism layers on the moving piston so that the layers are not remeshed, and therefore the risk of generating degenerate cells during the mesh motion update is reduced.

Figure 10.41: Expanding Cylinder After Region Face Remeshing
It is preferable (and even mandatory, if the mesh is a half model with a symmetry plane) to decompose the volume such that the “corner” region of the prism layers (shown in the previous figure) exists entirely within the rigidly moving zone. This allows for the largest deformations without risking degenerate elements, because the prism normals of the remeshed cells are uniformly perpendicular to the faces undergoing remeshing.

If the range of motion does not allow you to encapsulate the entire corner region of the prism layers in a rigidly moving zone, it is recommended that you encapsulate the “base” of the prism layers (shown in Figure 10.43: Volume Decomposition for the Base of the Prism Layers (p. 611)) and move these cells with a rigid body motion. Although this is less ideal than encapsulating the corner region, it does reduce the risk of degenerate mesh elements.
For piston-type applications that contain prism layers, a reasonable rule of thumb is that you should decompose the mesh volume if the piston motion is more than half the cylinder height. If you decide not to decompose the volume at all, you must at the very least enable the **Deform Adjacent Boundary Layer with Zone** option in the **Meshing Options** tab of the **Dynamic Mesh Zone** dialog box when setting up the moving face zone (see **Rigid Body Motion (p. 654)** for details). In any case, it is recommended that you always preview the mesh motion over the complete simulation time, to make sure that you will have a valid mesh at each time step.

The prism layer parameters (that is, element height, growth rate, and number of layers) are extracted automatically from the mesh and do not generally require your input. To prevent the prism parameters from drifting due to repeated remeshing, the prism parameters for first height, growth rate, and number of layers can be entered manually, using the text commands available in the **define/dynamic-mesh/controls/remeshing-parameters/prism-layer-parameters** menu.

### 10.6.2.3.3.2. Applicability of the Face Region Remeshing Method

Note the following limitations associated with face region remeshing:
• You can use the face region remeshing method only in cell zones that contain triangular cells (in 2D) or tetrahedral cells, with or without prism layers (in 3D). For 3D meshes, the faces on the deforming boundaries that border the moving face must all be triangular.

• The face region remeshing method is not compatible with diffusion-based smoothing or linearly elastic solid smoothing.

• You cannot use the face region remeshing method in conjunction with hanging node adaption. For more information on hanging node adaption, see Hanging Node Adaption in the Theory Guide.

10.6.2.3.4. CutCell Zone Remeshing Method

The CutCell zone remeshing method is available to remesh a complete cell zone (including all boundary zones of the remeshed cell zone). This method is available for 3D simulations only. The existing volume mesh is replaced by a predominantly Cartesian mesh. Inflation layers can be added as an option. When used as part of a transient simulation, the remeshing occurs at predefined intervals and whenever the mesh quality in the cell zone is deemed poor. Examples of meshes before and after CutCell zone remeshing are shown in Figure 10.44: Unstructured Tetrahedral Mesh Before CutCell Zone Remeshing (p. 612) and Figure 10.45: Mesh After CutCell Zone Remeshing (p. 613), respectively. Figure 10.46: CutCell Zone Remeshing With Inflation Layers (p. 613) shows a cut through a CutCell mesh with inflation layers.

Figure 10.44: Unstructured Tetrahedral Mesh Before CutCell Zone Remeshing
During CutCell zone remeshing, a uniform Cartesian grid is locally refined using size functions, in order to resolve the initial mesh with sufficient accuracy. The resulting mesh consists mostly of hexahedral elements, which reduces the cell count compared to unstructured tetrahedral meshing. Additional element types are used near the boundaries to closely resolve complex shapes. The remeshing takes place at regular intervals, or whenever the mesh quality deteriorates due to mesh motion.

The CutCell zone remeshing method not only replaces the volume mesh, it also replaces the complete surface mesh of the remeshed cell zone. Consequently, this method can only be used to remesh cell zones that are either stand-alone zones or are only connected to other cell zones through non-conformal
interfaces. If inflation layers are added to a CutCell mesh, the inflation layers are grown from the remeshed surface mesh, and the CutCell mesh is morphed such that it smoothly matches the cap surfaces of the inflation layers.

The CutCell Zone remeshing method option is available in the Remeshing Methods group box. Note that the CutCell Zone remeshing method does not use any of the parameters specified in the Mesh Method Settings dialog box. The parameters used to control CutCell Zone remeshing are specified in the Dynamic Mesh Zones dialog box when setting up the zone and boundaries.

For more information about CutCell meshes, see the Fluent Meshing User’s Guide.

10.6.2.3.4.1. Applicability of the CutCell Zone Remeshing Method

The CutCell zone remeshing method can be applied to cell zones, with the following limitations:

- The case must be 3D.
- The cell zone cannot be conformally connected to other cell zones; that is, a CutCell zone must be a stand-alone cell zone, or can only be connected to another zone through a non-conformal interface. In the latter case, the non-conformal interface is cleared before the remeshing and automatically recreated after the remeshing.

Note that the CutCell zone remeshing method can be applied to cell zones that contain adapted cells.

In parallel, all cells of the remeshed zone will be automatically migrated to and remeshed on a single CPU. Consequently, the machine memory will limit the size of the zone that can be remeshed. The mesh is automatically repartitioned after the remeshing.

In addition to the limitations listed previously, you should also note the following with regard to CutCell zone remeshing:

- Internal coupled walls, such as baffles, are discarded during the remeshing. The method is designed to primarily remesh cell zones with a single interior zone.
- Interior jump boundary condition zones (for example, fans, porous jumps), are discarded during the remeshing.
- Conformal periodic boundary conditions are not maintained after the remeshing. Any existing conformal periodic boundaries on the zone being remeshed should slit and replaced with non-conformal periodic boundaries.
- If the zone being remeshed contains multiple interior zones prior to the remeshing, all interior zones will be collected into a single interior zone during the CutCell zone remeshing.

10.6.2.3.4.2. Using the CutCell Zone Remeshing Method

In order to apply CutCell zone remeshing to a cell zone, begin by enabling the CutCell Zone option in the Remeshing Methods group box in the Remeshing tab of the Mesh Method Settings dialog box (see Figure 10.33: The Remeshing Tab in the Mesh Method Settings Dialog Box (p. 598)). Next, use the Dynamic Mesh Zones dialog box to create a deforming dynamic zone for the cell zone (see Deforming Motion (p. 657)). Then enable CutCell in the Remeshing Options group box and enter the relevant remeshing parameters, including: the maximum mesh size for the Cartesian cells; the global size function growth rate; the minimum orthogonal quality and remeshing interval to control the remeshing frequency; and the optional global inflation layer settings.
ANSYS Fluent allows you to specify either a soft or a mesh-based size function to control how the Cartesian mesh increases in size from the boundary toward the interior of the cell zone. For the soft size function, you specify a maximum mesh size for each boundary zone of the CutCell cell zone. When you use the mesh-based size function, ANSYS Fluent analyzes the existing mesh to evaluate the necessary mesh refinement at the boundary. See step 4 of Stationary Zones (p. 651) for more information about these size functions. You have control over the size function types and parameters by defining the boundary zones as dynamic zones. If no boundary zone adjacent to the CutCell zone is defined as a dynamic zone, ANSYS Fluent will automatically apply mesh-based size functions to each CutCell boundary zone and use the global growth rate entered for the cell zone to control the remeshing.

Note that the size functions used by the CutCell zone remeshing method are unrelated to the size function used for local cell remeshing (as described in Local Remeshing Based on Size Functions (p. 600)).

ANSYS Fluent allows you to add inflation layers to a CutCell mesh in order to better resolve wall-bounded flow features. After enabling Inflation Layers under the CutCell Zone Parameters for the CutCell cell zone, you can specify the global inflation parameters in the Inflation Settings dialog box. There are two types of inflation layers available: a constant type, where you can specify the constant height of the first layer; and an aspect-ratio type, where the first layer height is locally evaluated based on the specified aspect ratio. The latter is recommended and used by default since it is more robust and generally produces higher quality CutCell meshes. By default, the inflation settings specified apply to every boundary of the cell zone. If you would like to specify different inflation settings for different boundaries, you can define these boundaries as dynamic zones and enable Zonal Inflation Layer Control. Note that the Number of Layers, other than 0, has to be the same on all boundary zones. If different numbers of layers are specified on different boundaries, ANSYS Fluent will only inflate up to the largest common number specified. By setting the number of layers on a boundary zone to 0, you can locally suppress the growth of inflation layers, however, note that the transition is handled by stair stepping and adding wedge elements, which tends to generate skewed elements for small layer element heights.

The cells that contain hanging nodes / edges as a result of the CutCell zone remeshing are automatically converted to polyhedral cells. See Limitations (p. 142) for details about limitations associated with polyhedral cells.

It is recommended that you first manually apply the CutCell zone remeshing method (as described in the section that follows) and inspect the mesh before using the method as part of a transient simulation, as this allows you to evaluate if your remeshing parameters are suitable before running a calculation that is computationally expensive.

10.6.2.3.4.3. Applying the CutCell Zone Remeshing Method Manually

Although the CutCell zone remeshing method is primarily intended as an automatic remeshing method during dynamic mesh updates, you can also manually create a CutCell mesh (that is, you can remesh without running a calculation) by using the following text command:

```
define → dynamic-mesh → actions → remesh-cell-zone-cutcell
```

You will be prompted to enter the global parameters for the CutCell zone remeshing. If no dynamic zones are set up in your case, ANSYS Fluent will use the global parameters you enter and apply mesh-based size functions to each boundary of the CutCell zone. If the case is set up as a dynamic mesh case, manual remeshing will use the information specified on each CutCell boundary zone, including the zonal inflation layer settings. During manual CutCell zone remeshing, the global parameters are taken from the text interface input, and the global parameters specified on the CutCell cell zone are ignored.

When executing manual remeshing through the `remesh-cell-zone-cutcell` text command, you will be prompted to specify whether topology warnings should be ignored. If you do not ignore the
topology warnings, ANSYS Fluent will analyze the zone being remeshed and report any interior face zones that will get discarded during the remeshing. If the zone being remeshed has periodic boundary zones, you will also be prompted to either abort the remeshing process or slit the periodics in order to proceed.

You will also be prompted to specify whether the cells that contain hanging nodes / edges as a result of the CutCell zone remeshing should be converted to polyhedral cells. See Limitations (p. 142) for details about limitations associated with polyhedral cells. By default, all hanging node cells are converted to polyhedral cells.

### 10.6.2.3.5. 2.5D Surface Remeshing Method

The 2.5D surface remeshing method only applies to extruded 3D geometries and is similar to local remeshing in two dimensions on a triangular surface mesh (not a mixed zone). Faces on a deforming boundary are marked for remeshing based on face skewness, minimum and maximum length scale; the 2.5D remeshing method also gives you the option of marking cells using size functions, as described in Local Remeshing Based on Size Functions (p. 600).

**Figure 10.47: Close-Up of 2.5D Extruded Flow Meter Pump Geometry Before Remeshing and Laplacian Smoothing**

![2.5D Extruded Flow Meter Pump Geometry Before Remeshing and Laplacian Smoothing](image-url)
**Figure 10.48: Close-Up of 2.5D Extruded Flow Meter Pump Geometry After Remeshing and Laplacian Smoothing**

### 10.6.2.3.5.1. Applicability of the 2.5D Surface Remeshing Method

The following applies to the 2.5D surface remeshing method:

- Triangular faces get remeshed based on marking.
- Extruded wedges get remeshed based on the remeshing of the triangular face. Only extruded regions get remeshed, not mixed regions.
- The 2.5D remeshing method does not support remeshing or moving nodes on the perimeter of the extruded zone(s).
- Note that you cannot use the 2.5D surface remeshing method in conjunction with hanging node adaption. For more information on hanging node adaption, see [Hanging Node Adaption](#) in the Theory Guide.
- The extrusion must be along a straight line normal to the deforming zone and the cross-section of the extruded/coopered mesh must be constant along the extrusion direction. For more information about the 2.5D model, see [Using the 2.5D Model](#).
- Periodics are not supported at the extruded zones.

### 10.6.2.3.5.2. Using the 2.5D Model

For 3D simulations only, you can select the 2.5D model under the Remeshing tab in the Mesh Method Settings Dialog Box (p. 2177). This model allows for a specific subset of remeshing techniques.
The 2.5D mesh essentially is a 2D triangular mesh which is expanded, or extruded, along the normal axis of the specific dynamic zone that you are interested in modeling. The triangular surface mesh is remeshed and smoothed on one side, and the changes are then extruded to the opposite side. Rigid body motion is applied to the moving face zones, while the triangular extrusion surface is assigned to a deforming zone with remeshing and smoothing enabled. The opposite side of the triangular mesh is assigned to be a deforming zone as well, with only smoothing enabled, as in Figure 10.50: 2.5D Extruded Gear Pump Geometry (p. 619).

**Figure 10.49: The Remeshing Tab for the 2.5D Model**

For more information on setting smoothing and remeshing parameters, see Dynamic Mesh Update Methods (p. 576).

The 2.5D model only applies to mappable (that is, extrudable) mesh geometries such as pumps, as in Figure 10.50: 2.5D Extruded Gear Pump Geometry (p. 619). Only the aspects of the geometry that represent the “moving parts” must be extruded in the mesh.
**Important**

You must only apply smoothing to the opposite side of the extruded mesh, since ANSYS Fluent requires the geometry information for the dynamic zone. ANSYS Fluent projects the nodes back to its geometry after the extrusion. Without this geometry information, the dynamic zones tends to lose its integrity.

**Important**

In parallel, a partition method that partitions perpendicular to the extrusion surface should be used. For example, if the normal of the extrusion surface points in the x-direction then Cartesian-Y or Cartesian-Z would be the perfect partition methods.

The 2.5D model is used in combination with a `DEFINE_GRID_MOTION` UDF. (See Hooking `DEFINE_GRID_MOTION` UDFs in the UDF Manual for information about hooking this UDF.)

This UDF is associated with the extrusion surface that is adjacent to the cell zone, in turn applying the same deformation to the entire cell zone. This approach is particularly useful when modeling gear pumps that are predominantly extruded hexahedral meshes. For more information about this UDF, contact your support engineer.

**10.6.2.3.6. Feature Detection**

For 3D simulations, ANSYS Fluent allows you to preserve features on deforming zones not only between the different face zones, but also within a face zone.
In the **Geometry Definition** tab of the **Dynamic Mesh Zones Dialog Box** (p. 2190), for any geometry definition, you can indicate whether you want to include features of a specific angle by selecting **Include Features** under **Feature Detection** and setting the **Feature Angle** (the zonal feature angle $\alpha$) in degrees. If the angle $\beta$ between adjacent faces is bigger than the specified angle, then the feature is recognized (that is, $\cos(\beta) < \cos(\alpha)$).

### 10.6.2.3.6.1. Applicability of Feature Detection

The following items are applicable for use with feature detection:

- Feature remeshing is only possible with face region remeshing.

- Features are preserved by local face remeshing, that is, there is no local face remeshing across features.

- Smoothing methods preserve features, that is, nodes at feature edges are not allowed to be smoothed.

### 10.6.2.4. Volume Mesh Update Procedure

The volume mesh is updated automatically based on the methods described in **Dynamic Mesh Update Methods** (p. 576). ANSYS Fluent decides which method to use for a particular zone based on which model is enabled and the shape of the cells in the zone. For example, if the boundaries of a tetrahedral cell zone are moving, and unless the zone has been set up for CutCell zone remeshing, the mesh smoothing and local remeshing methods will be used to update the volume mesh in this zone. If the zone consists of prismatic (hexahedral and/or wedge) cells, then the dynamic layer method will be used to determine where and when to insert and remove cell layers. On extruded prism zones, the 2.5D surface meshing method will be used.

Depending on which model is enabled, ANSYS Fluent automatically determines which method to use by visiting the adjacent cell zones and setting appropriate flags for the volume mesh update methods to be used. If you specify the motion for a cell zone, ANSYS Fluent will visit all of the neighboring cell zones and set the flags appropriately. If you specify the motion of a boundary zone, ANSYS Fluent will analyze only the adjacent cell zones. If a cell zone does not have any moving boundaries, then no volume mesh update method will be applied to the zone.

**Important**

Note that as a result of the remeshing procedures, updated meshes may be slightly different when dynamic meshes are used in parallel ANSYS Fluent, and therefore very small differences may arise in the solutions.

**Important**

Note that if your dynamic mesh model consists of numerous shell conduction zones, the mesh update may be very time consuming because all shells are deleted and recreated during the mesh update.

### 10.6.2.5. Transient Considerations for Remeshing and Layering

The second order in time transient formulation can be used with remeshing, layering, and smoothing cases. In such cases, second order in time accuracy is preserved during layering events and/or mesh smoothing. However, during remeshing events, the time advancement accuracy reverts to first order.
Therefore, it is recommended that you only use second order in time for cases with very low remeshing frequency, that is, for cases where remeshing occurs every several timesteps or more. If remeshing occurs every timestep, the method reduces to a first order formulation. For cases that need very frequent remeshing, it is recommended that you retain the first order in time formulation. For details, see Dynamic Mesh Theory in the Fluent Theory Guide.

The switch to first order happens automatically when the solver detects a topology change as a result of remeshing within a timestep. You will not see a change in the user interface, however you can monitor the switch between first and second order in time by using the following text command to activate the verbosity with dynamic meshes:

```
define → dynamic-mesh → transient-settings → verbosity
```

A message showing the active time formulation will print to the console when verbosity is set to 1.

---

**Note**

For cases with second order in time with dynamic mesh enabled, any mesh swapping and manual mesh manipulation will trigger a switch to first order in time.

---

### 10.6.3. In-Cylinder Settings

You can enable the **In-Cylinder** option in the Dynamic Mesh Task Page (p. 2175) (Figure 10.13: The Dynamic Mesh Task Page (p. 575)) for transient problems. Then click the **Settings**... button in the **Options** group box to open the Options Dialog Box (p. 2181). Click the **In-Cylinder** tab and specify the **Crank Shaft Speed**, the **Starting Crank Angle**, and the **Crank Period**, which are used to convert between flow time and crank angle. You must also specify the time step to use for advancing the solution in terms of crank angle in **Crank Angle Step Size**. By default, ANSYS Fluent assumes a **Crank Angle Step Size** of 0.5 degrees.
Figure 10.51: The In-Cylinder Tab of the Options Dialog Box

ANSYS Fluent provides a built-in function that can define the location of the piston as a function of crank angle. This function is named **piston-full**, and is selected from the Motion/UDF Profile drop-down list in the Dynamic Mesh Zones dialog box as part of rigid body motion (see Rigid Body Motion (p. 654) for details). If you plan to specify the piston motion using this function, you must specify the Crank Radius (that is, the distance between the crank center and the center of the crank pin) and the Connecting Rod Length. You also have the option of entering a value for the Piston Pin Offset for cases when the piston pin is offset perpendicularly from the plane defined by the crank shaft axis and the direction of motion of the piston. The sign of this offset can be positive or negative, and is determined based on the geometry and the direction of rotation of the crank shaft (as shown in Figure 10.52: Determining the Sign of the Piston Pin Offset (p. 623)).
Figure 10.52: Determining the Sign of the Piston Pin Offset

When the **piston-full** function is used, the piston location is calculated according to the following equation:

\[ p_s = \sqrt{(r_c + L)^2 - x_{\text{offset}}^2} - r_c \cos(\theta_c) - \sqrt{L^2 - (r_c \sin(\theta_c) + x_{\text{offset}})^2} \]  

(10.25)

where \( p_s \) is the piston location, \( r_c \) the crank radius, \( L \) is the connecting rod length, \( x_{\text{offset}} \) is the piston pin offset, and \( \theta_c \) is the current crank angle.

The piston location \( p_s \) is always 0 at top-dead-center (TDC), that is, when the crank pin is perfectly aligned between the piston pin and the center of rotation of the crank shaft. TDC occurs when the crank angle is 0° when there is no piston pin offset, and prior to the crank angle reaching 0° when there is a positive piston pin offset. The piston location is a positive value at bottom-dead-center (BDC), that is, when the crank shaft is perfectly aligned between the piston pin and the crank pin. The value of \( p_s \) at BDC is equal to \( 2r_c \) when there is no piston pin offset, and greater than \( 2r_c \) when there is a non-zero piston pin offset (positive or negative).

The current crank angle \( \theta_c \) is calculated from

\[ \theta_c = \theta_s + t \Omega_{\text{shaft}} \]  

(10.26)

where \( \theta_s \) is the Starting Crank Angle and \( \Omega_{\text{shaft}} \) is the Crank Shaft Speed.

The Piston Stroke Cutoff and Minimum Valve Lift values are used to control the actual values of the valve lift and piston stroke such that

\[ v_{\text{lift}} = \max\left(v^c_{\text{lift}}, v_{\text{lift}}^{\text{min}}\right) \]

\[ p_s = \min\left(p^c_s, p_s^{\text{min}}\right) \]  

(10.27)

where \( v^c_{\text{lift}} \) is the valve lift computed from the appropriate valve profiles, \( v_{\text{lift}}^{\text{min}} \) is the Minimum Valve Lift, \( p^c_s \) is the stroke calculated from Equation 10.25 (p. 623), and \( p_s^{\text{min}} \) is the Piston Stroke Cutoff. (See Defining Motion/Geometry Attributes of Mesh Zones (p. 630) on how the Piston Stroke Cutoff is used to control the onset of layering in the cylinder chamber.)
Enable the **Write In-Cylinder Output** option then click the **Output Controls...** button if you want to specify specific output parameters. The **In-Cylinder Output Controls Dialog Box (p. 2184)** will open, where you can specify various quantities needed for the calculation of swirl and tumble along with the frequency of writing the output to the chosen file. Swirl is used to describe circulation about the cylinder axis. Tumble flow circulates around an axis perpendicular to the cylinder axis, orthogonal to swirl flow.

**Figure 10.53: The In-Cylinder Output Controls Dialog Box**

The following list describes the **In-Cylinder Output Controls Dialog Box (p. 2184)**.

**In-Cylinder Data Write Frequency**
- is an integer entry specifying the interval in number of time-steps. Make sure that a value other than 0 is used for the frequency, in order to allow you to complete your setup.

**Swirl Center Method**
- is a drop-down list that allows you to select the method to calculate the swirl center. The list contains **center of gravity** and **fixed**, with **center of gravity** being the default value.
  - **center of gravity** option calculates the swirl center inside the code and is used as the center of gravity of the chosen cell zones.
  - **fixed** option enables you to specify a swirl center in the entries below the drop-down list.

In addition to these two options, you can chose to use your own compiled UDF to calculate the swirl center.
For details on using a dynamic mesh UDF, see the UDF Manual for information on user-defined functions.

Cell Zones
is a list that displays the names of all existing cell zones in the case files. You can select only the zones relevant for the swirl and tumble calculations.

Swirl Axis
specifies the swirl axis with three entries for the directional components. By default, $X, Y, Z = 0, 1, 0$.

Tumble Axis
specifies the directional components of Tumble Axis in $X, Y, Z$ directions. By default, $X, Y, Z = 0, 0, 1$. This applies only in 3D.

Cross Tumble Axis
specifies the directional components of Cross Tumble Axis in $X, Y, Z$ directions. By default, $X, Y, Z = 0, 0, 1$. This applies only in 3D.

File Name
specifies the name of the In-Cylinder output file. By default, the file name contains the name of the case file appended with a .txt extension.

The In-Cylinder specific output controls can also be controlled using the TUI as follows:

Go to
define/dynamic-mesh/controls/in-cylinder-output?
Enable in-cylinder output?[no] yes
Output Write Frequency[0] 10
Cell zone name/id(1)[()] 2
Cell zone name/id(1)[()]
File Name["/nfs/devvault/data9/ic-sp-output.txt"]
Swirl Center Method: (fixed cg user-defined)
  Option[cc]
  Swirl Axis x[0]
  Swirl Axis y[1]
  Swirl Axis z[0]
  Tumble Axis x[0]
  Tumble Axis y[0]
  Tumble Axis z[1]
  Cross Tumble Axis x[1]
  Cross Tumble Axis y[0]
  Cross Tumble Axis z[0]

If you select fixed as the choice at Swirl Center Method then you will be prompted to enter the swirl center as follows:

  Swirl Center(x) (mm) [0]
  Swirl Center(y) (mm) [0]
  Swirl Center(z) (mm) [0]

If a swirl center method UDF has been compiled already and loaded into UDF then you can choose user-defined as the swirl center method option, in such a case the following is the sequence of prompts.

  Swirl Center UDF[] swirl_udf::libudf

If the name of the UDF library is libudf then you can omit this and enter in the swirl center UDF[]swirl_udf, otherwise the name of the UDF followed by the UDF library name with symbol:: in between, should be entered.
By filling up the various entries that are needed in the **In-Cylinder Output Controls Dialog Box (p. 2184)** and pressing the **OK** button, the swirl and tumble calculations will be written at the chosen frequency to the chosen file while doing the solution run. Details of the quantities written to the file are as follows:

**CA** = Crank Angle

**m** = Mass of the entire fluid contained in the selected cell zones

**L** = Angular momentum vector of fluid mass contained in selected cell zones with respect to the swirl center

\[ \vec{L} \] = Magnitude of angular momentum of fluid

\[ \vec{s}a \] = Swirl Axis

\[ \vec{t}a \] = Tumble Axis

\[ \vec{c}ta \] = Cross Tumble Axis

\[ I_{sa} \] = Moment of inertia of the fluid mass about Swirl axis

\[ I_{ta} \] = Moment of inertia of the fluid mass about Tumble Axis

\[ I_{cta} \] = Moment of inertia of the fluid mass about Cross Tumble Axis

\[ \cdot \] = Dot product between two vectors

Altogether, the previous quantities are combined to yield eight columns of data in the output file, as shown in the figure that follows:

**Figure 10.54: Sample Output File Showing Various Quantities**

| CA  | (L . sa) | (L . ta) | (L . cta) | |L| | I_{sa} | I_{ta} | I_{cta} |

**10.6.3.1. Using the In-Cylinder Option**

This section describes the problem setup procedure for an in-cylinder dynamic mesh simulation.

**10.6.3.1.1. Overview**

Consider the 2D in-cylinder example shown in **Figure 10.55: A 2D In-Cylinder Geometry (p. 627)** for a typical pent-roof engine.
In setting up the dynamic mesh model for an in-cylinder problem, you must consider the following issues:

- how to provide the proper mesh topology for the volume mesh update methods (smoothing, dynamic layering, and local or zonal remeshing)
- how to define the motion attributes and geometry for the valve and piston surfaces
- how to address the opening and closing of the intake and exhaust valves
- how to specify the sequence of events that controls the in-cylinder simulation

### 10.6.3.1.2. Defining the Mesh Topology

ANSYS Fluent requires that you provide an initial volume mesh with the appropriate mesh topology such that the various mesh update methods described in Dynamic Mesh Update Methods (p. 576) can be used to automatically update the dynamic mesh. However, ANSYS Fluent does not require you to set up all in-cylinder problems using the same mesh topology. When you generate the mesh for your in-cylinder problem, you must consider the various mesh regions that you can identify as moving, deforming, or stationary, and generate these mesh regions with the appropriate cell shape.

The mesh topology for the example problem in Figure 10.55: A 2D In-Cylinder Geometry (p. 627) is shown in Figure 10.56: Mesh Topology Showing the Various Mesh Regions (p. 628), and the corresponding volume mesh is shown in Figure 10.57: Mesh Associated With the Chosen Topology (p. 628).
Because of the rectilinear motion of the moving surfaces, you can use dynamic layering zones to represent the mesh regions swept out by the moving surfaces. These regions are the regions above the top surfaces of the intake and exhaust valves and above the piston head surface, and must be meshed with quadrilateral or hexahedral cells (as required by the dynamic layering method).
For the chamber region, you must define a remeshing zone (triangular cells) to accommodate the various positions of the valves in the course of the simulation. In this region, the motion of the boundaries (valves and piston surfaces) is propagated to the interior nodes through smoothing. If the cell quality violates any of the remeshing criteria that you have specified, ANSYS Fluent will automatically agglomerate these cells and remesh them. Furthermore, ANSYS Fluent will also remesh the deforming faces (based on the minimum and maximum length scale that you have specified) on the cylinder walls as well as those on the sliding interfaces used to connect the chamber cell zone to the layering zones above the valve surfaces.

For the intake and exhaust port regions, you can use either triangular or quadrilateral cell zones because these zones are not moving or deforming. ANSYS Fluent will automatically mark these regions as stationary zones and will not apply any mesh motion method on these cell zones.

The dynamic layering regions above the piston and valves are conformal with the adjacent cell zone in the chamber and ports, respectively, so you do not have to use sliding interfaces to connect these cell zones together. However, you must use sliding interfaces to connect the dynamic layering regions above the valves and the remeshing region in the chamber. This is shown in Figure 10.58: The Use of Sliding Interfaces to Connect the Exhaust Valve Layering Zone to the Remeshing Zone (p. 629) with the exhaust valve almost at full extension. Notice that cells on the chamber side of the interface zone are remeshed (that is, split or merged) as the interface zone opens and closes because of the motion of the exhaust valve.

**Figure 10.58: The Use of Sliding Interfaces to Connect the Exhaust Valve Layering Zone to the Remeshing Zone**
10.6.3.1.3. Defining Motion/Geometry Attributes of Mesh Zones

As the piston moves down from the TDC to the BDC position, you must expand the remeshing region such that it can accommodate the valves when they are fully extended. To accomplish this, you must specify the dynamic layering zone adjacent to the piston surface to move with the piston until some specified distance from the TDC position. Beyond this cutoff distance, the motion of the layering zone is stopped and the piston wall is allowed to continue to the BDC position. Because there is relative motion between the piston head surface and the now non-moving dynamic layering zone, cell layers will be added when the ideal layer height criteria is violated. Figure 10.59: Mesh Sequence 1 (p. 630) to Figure 10.64: Mesh Sequence 6 (p. 633) show the sequence of meshes before and after the onset of cell layering when the motion in the layering zone above the piston surface is stopped (shown with $\Delta \theta = 5^\circ$).

**Figure 10.59: Mesh Sequence 1**

![Mesh Sequence 1](image-url)
Figure 10.60: Mesh Sequence 2

Figure 10.61: Mesh Sequence 3
Figure 10.62: Mesh Sequence 4

Figure 10.63: Mesh Sequence 5
ANSYS Fluent provides built-in functions to handle the full piston motion and the limited piston motion for the dynamic layering zone above the piston surface. When you define the motion attribute of the dynamic layering zone above the piston surface, you must use the limited piston motion function (**piston-limit** in the Motion UDF/Profile field in the Dynamic Mesh Zones Dialog Box (p. 2190)). Note that you must define the parameters used by these functions before you can use them. In the current example, the crank radius is 40 mm and the connecting rod length is 140 mm. The piston stroke cutoff is assumed to happen at 25 mm from TDC position. The lift as a function of crank angle between $344^\circ$ and $1064^\circ$ is shown in Figure 10.65: Piston Position (m) as a Function of Crank Angle (deg) (p. 634) for both limited and full piston motion.
To define the motion of the valves, you must use profiles that describe the variation of valve lift with crank angle. ANSYS Fluent expects certain profile fields to be used to define the lift and the crank angle. For example, consider the following simplified profile definition:

```
((ex-valve 5 point)
 (angle 0 180 270 360 720)
 (lift 0.05 0.05 1.8 0.05 0.05))

((in-valve 5 point)
 (angle 0 355 440 540 720)
 (lift 0.05 0.05 2.0 0.05 0.05))
```

ANSYS Fluent expects the `angle` and `lift` fields to define the crank angle and lift variations, respectively. The angle must be specified in degrees and the lift values must be in meters. The actual valve lift profiles that you will use for the current example are shown in Figure 10.66: Intake and Exhaust Valve Lift (m) as a Function of Crank Angle (deg) (p. 635). Notice that there is an overlapped period where both the intake and exhaust valves are open.
The valve lift profiles and the built-in functions will describe how each surface moves as a function of crank angle with respect to some reference point. For example, the valve lift is zero when the valve is fully closed and the valve lift is maximum when it is fully open. In order to move the surfaces, ANSYS Fluent requires that you specify the direction of motion for each surface. ANSYS Fluent will then update the “center of gravity” of each surface such that

\[ \bar{x} = \bar{x}_{\text{ref}} - l \bar{e}_{\text{axis}} \]  \hspace{1cm} (10.28)

where \( \bar{x}_{\text{ref}} \) is some reference position, \( \bar{e}_{\text{axis}} \) is the unit vector in the direction of motion, and \( l \) is either the valve or the piston distance with respect to the reference position \( \bar{x}_{\text{ref}} \). Note that the unit vector of the direction of motion is specified to point in the negative direction. For example, the correct intake valve axis for this example is \( (-0.3421, 0.9397) \), as shown in Figure 10.67: Definition of Valve Zone Attributes (Intake Valve) (p. 636).
10.6.3.1.4. Defining Valve Opening and Closure

ANSYS Fluent assumes that once you have set up the mesh topology, the mesh topology is unchanged throughout the entire simulation. Therefore, ANSYS Fluent does not allow you to completely close the valves such that the cells between the valve and the valve seat become degenerate (flat cells) when these surfaces come in contact (removing these flat cells would require the creation of new boundary face zones). To prevent the collapse, you must define a minimum valve lift and ANSYS Fluent will automatically stop the motion of the valve when the valve lift is smaller than the minimum valve lift value. The minimum valve lift value can be specified in the In-Cylinder tab of the Options Dialog Box (p. 2181). For the current example, a minimum valve lift value of 0.1 mm is assumed.

When the valve position is smaller than the minimum valve lift value, it is normal practice to assume that the valve is closed. The actual closing of the valves is accomplished by deleting the sliding interfaces that connect the chamber cell zone to the dynamic layering zones on the valves. The interface zones are then converted to walls to close off the “gaps” between the valves and the valve seats.

The valve opening is achieved by the reverse process. When the valve lift has reached beyond the minimum valve lift value, the valve is assumed to be open and you can redefine the sliding interfaces such that the chamber zone is now connected to the dynamic layering zones above the valves.

10.6.4. Six DOF Solver Settings

To use the six degree of freedom solver for your transient dynamic mesh simulation, select Six DOF under Options in the Dynamic Mesh Task Page (p. 2175) (Figure 10.13: The Dynamic Mesh Task Page (p. 575)) and click the Settings... button. The Options dialog box will open, where you can click the Six DOF tab (Figure 10.68: The Six DOF Tab of the Options Dialog Box (p. 637)).
You can specify the gravitational acceleration in the $x$, $y$, and $z$ directions either in this dialog box, or in the **Operating Conditions** dialog box. Note that you can also keep track of an object’s motion history by selecting the check box next to **Write Motion History**. A single motion history file will be generated for each moving object, which can be used to display zone motion for postprocessing your results. Enter the file name in the **File Name** text entry box and click OK (Figure 10.68: The Six DOF Tab of the Options Dialog Box (p. 637)).

### 10.6.4.1. Using the Six DOF Solver

ANSYS Fluent’s six degree of freedom (six DOF) solver computes external forces and moments such as aerodynamic and gravitational forces and moments on an object. These forces are computed by numerical integration of pressure and shear stress over the object’s surfaces. Additional load forces can be added (for example, injector forces, thrust (propulsive) forces, moments produced by a coil spring, etc.). This technique, along with the ANSYS Fluent solver and the use of dynamic meshes, can be readily applied to many useful applications, such as store separation [89] (p. 2561), [96] (p. 2562). Note that if the mesh motion of your six DOF simulation depends on the fluid flow, it is beneficial to also enable implicit mesh updating (as described in Implicit Update Settings (p. 638)).

### 10.6.4.1.1. Setting Rigid Body Motion Attributes for the Six DOF Solver

When the **Six DOF** solver is enabled, you must provide additional information for rigid body dynamic zones. For instance, you must use a user-defined function to define the six degrees of freedom parameters, and you must set the velocity and angular velocity for the center of gravity. Also, you must indicate whether the moving object is modeled as a half model with a symmetry plane. For each moving object, exactly one user-defined function has to be defined, no matter how many zones there are for each
object. For more information about specifying six DOF properties in the user-defined function, see `DEFINE_SDOF_PROPERTIES` in the Fluent UDF Manual. For more information about the Six DOF solver settings in the Dynamic Mesh Zones Dialog Box (p. 2190) or rigid body motion, see Rigid Body Motion (p. 654).

### 10.6.5. Implicit Update Settings

For transient problems, you can enable implicit mesh updating when you want to have the dynamic mesh updated during a time step (as opposed to just at the beginning of a time step). This capability is beneficial only for applications in which the mesh motion depends on the flow field (for example, cases that use the six DOF solver or involve fluid-structure interaction). For such applications, having the mesh motion updated within the time step based on the converging flow solution results in a stronger coupling between the flow solution and the mesh motion, and leads to a more robust solver run. Implicit mesh updating allows you to run simulations that otherwise could not be solved or would require an unreasonably small time step.

Note that implicit mesh updating cannot be used with the following:

- the density-based solver when Explicit is selected from the Transient Formulation drop-down menu in the Solution Methods task page
- steady state solutions
- in-cylinder applications

To enable implicit mesh updating, perform the following steps:

1. Enable Implicit Update in the Options group box of the Dynamic Mesh Task Page (p. 2175) (Figure 10.13: The Dynamic Mesh Task Page (p. 575)).

2. Click the Settings... button to open the Options Dialog Box (p. 2181).
Click the **Implicit Update** tab and enter values for the settings.

a. Enter a value for **Update Interval**, in order to specify the frequency in iterations at which the mesh will be updated within a time step.

b. Enter a value (within the range of 0 to 1) for **Motion Relaxation**, in order to define the relaxation of the motion (that is, displacement of the nodes) during the mesh update. The relaxation of the displacements is defined by the following equation:

\[
x_k = \omega (x_{computed,k}) + (1 - \omega)x_{k-1}
\]  

(10.29)

where \( x_k \) is the node position at iteration \( k \) (within a time step), \( x_{computed,k} \) is the computed node position (based on the flow field), and \( \omega \) is the motion relaxation.

c. Enter a value for **Residual Criteria**, in order to set the relative residual threshold that is used to check the motion convergence. The residual criteria is applied to a relative residual. ANSYS Fluent scales the difference between the motion in iteration \( k \) and iteration \( k - 1 \) by the motion computed at the beginning of the time step. If this relative motion difference is smaller than the residual criteria, the mesh motion is considered converged.

3. If you are using a UDF to compute the motion, make sure that the UDF uses the current flow field during each call to compute the motion (that is, no previously stored information should be used). This is necessary, as the UDF will be called each time the mesh is updated — which can be several times within a time step, depending on what you entered for the **Update Interval**.
4. After you run the simulation, make sure that the motion (and consequently, the solution) is properly converged. If the motion requires more iterations to converge than the flow field, a warning will be displayed in the console during the iteration process. Note that the maximum number of iterations per time step (defined in the Run Calculation task page) is respected by the mesh motion convergence check.

10.6.6. Contact Detection Settings

Contact detection is used to detect if the computed mesh motion will result in contact of a moving surface with other surrounding surfaces. If there is contact within specified tolerances, then the mesh motion of the moving zone can be constrained using nodal contact information within user-defined functions (See Example 2 under DEFINE_CONTACT in the Fluent UDF Manual).

To enable contact detection in your dynamic mesh simulation, select the Contact Detection check box in the Options group of the Dynamic Mesh task page. Click the Settings... button to open the Options dialog box and select the Contact Detection tab (see Figure 10.70: The Contact Detection Tab of the Options Dialog Box (p. 640)).

Figure 10.70: The Contact Detection Tab of the Options Dialog Box

You can select the face zones that will be involved in the contact detection process from the Face Zones list. While all eligible face zones in the Face Zones list are selected by default, you can choose to exclude certain zones for efficiency. Only walls and dynamic zones of type Rigid Body or User-Defined can be selected for contact detection. Dynamic zones of the type System Coupling cannot be used with contact detection.
From the UDF drop-down list, you can specify a user-defined function that will be invoked when contact has been detected. For more information about contact UDFs, see DEFINE_CONTACT in the UDF Manual.

You must specify a Proximity Threshold value in order to activate the contact detection process. When the distance between face zones falls below this threshold value, the UDF specified in the UDF drop-down list is invoked.

Cells adjacent to face zones that fall below the Proximity Threshold distance can also be tagged and separated into new cell zones during the contact detection process. This is useful for specifying different flow conditions in contact regions during the simulation.

To enable flow control options, select the Flow Control check box in the Contact Detection tab. Additional settings for flow control can then be specified by clicking the Controls... button to display the Flow Controls dialog box (see Figure 10.71: The Flow Controls Dialog Box (p. 641)).

**Figure 10.71: The Flow Controls Dialog Box**

In the Flow Controls dialog box, you can specify a flow control zone (for example, restrictions, etc.) for any cell zone in the mesh. To create a flow control zone, select a zone from the Cell Zones list, specify a new name in the Flow Control Zone text box, and click the Create Zone button. Once the flow control zone has been created, it becomes available in the Cell Zone Conditions task page, where additional physical properties (for example, inertial and/or viscous porous resistance) can be specified. During the simulation, once cells in the contact region have been separated into new zones, the physical properties specified in the respective flow control zone are copied to the newly separated cell zone.

**10.6.7. Defining Dynamic Mesh Events**

If you are simulating a transient flow, you can use the events in ANSYS Fluent to control the timing of specific events during the course of the simulation. With in-cylinder flows for example, you may want to open the exhaust valve (represented by a pair of deforming sliding interfaces) by creating an event to create the sliding interfaces at some crank angle. You can also use dynamic mesh events to control when to suspend the motion of a face or cell zone by creating the appropriate events based on the
crank angle or time. Note that in-cylinder flows are crank angle-based, whereas all other flows are time-based.

**10.6.7.1. Procedure for Defining Events**

You can define the events using the Dynamic Mesh Events Dialog Box (p. 2186) (Figure 10.72: The Dynamic Mesh Events Dialog Box (p. 642)).

![Dynamic Mesh → Events...](image)

**Figure 10.72: The Dynamic Mesh Events Dialog Box**

The procedure for defining events is as follows:

1. Increase the **Number of Events** value to the number of events you want to specify. As this value is increased, additional event entries in the dialog box will become editable.

2. Enable the check box next to the first event and enter a name for the event under the **Name** heading.

3. Specify either the time or the crank angle at which you want the event to occur.

   For in-cylinder flows, specify the crank angle at which you want the event to occur under **At Crank Angle**.

   For non-in-cylinder flows, specify the time (in seconds) at which you want the event to occur under **At Time**.

   It is not necessary to specify the events in order of increasing time or crank angle, but it may be easier to keep track of events if you specify them in the order of increasing time or angle.
4. Click the Define... button to open the Define Event Dialog Box (p. 2188) (Figure 10.73: The Define Event Dialog Box (p. 643)).

**Figure 10.73: The Define Event Dialog Box**

![Define Event Dialog Box](image)

5. In the Define Event Dialog Box (p. 2188), choose the type of event by selecting Change Zone Type, Copy Zone BC, Activate Cell Zone, Deactivate Cell Zone, Create Sliding Interface, Delete Sliding Interface, Change Motion Attribute, Change Time Step Size, Change Under-Relaxation Factors, Insert Boundary Zone Layer, Remove Boundary Zone Layer, Insert Interior Zone Layer, Remove Interior Zone Layer, Insert Cell Layer, Remove Cell Layer, Execute Command, Replace Mesh, Inert EGR Reset, or Diesel Unsteady Flamelet Reset in the Type drop-down list. These event types and their definitions are described later in this section.

6. Repeat steps 2–5 for the other events, if relevant.

7. Click Apply in the Dynamic Mesh Events Dialog Box (p. 2186) after you finish defining all events.

8. To play the events to check that they are defined correctly, click the Preview... button in the Dynamic Mesh Events Dialog Box (p. 2186). This displays the Events Preview Dialog Box (p. 2190).

   For in-cylinder flows, you use the Events Preview Dialog Box (p. 2190) (Figure 10.74: The Events Preview Dialog Box for In-Cylinder Flows (p. 644)), to enter the crank angles at which you want to start and end the playback in the Start Crank Angle and End Crank Angle fields, respectively.

   For non-in-cylinder flows, you use the Events Preview Dialog Box (p. 2190) to enter the time at which you want to start and end the playback in the Start Time and End Time fields, respectively.

   Specify the size of the step to take during the playback in the Increment field. Click Preview to play back the events. ANSYS Fluent will play the events at the time (or crank angle in the case of in-cylinder flows) specified for each event and report when each event occurs in the text (console) window.
For in-cylinder simulations, you must specify the events for one complete engine cycle. In the subsequent cycles, the events are executed whenever
\[ \theta_{\text{event}} = \theta_c \pm n \theta_{\text{period}} \]  \hspace{1cm} (10.30)

where \( \theta_{\text{event}} \) is the event crank angle, \( \theta_c \) is the current crank angle calculated from Equation 10.26 (p. 623), \( \theta_{\text{period}} \) is the crank angle period for one cycle, and \( n \) is some integer.

As an example, for in-cylinder simulations, you are not required to specify the event crank angle to correspond exactly to the current crank angle calculated from Equation 10.26 (p. 623). ANSYS Fluent will execute an event if the current crank angle is between \( \pm 0.5 \Delta \theta \) where \( \Delta \theta \) is the equivalent change in crank angle for the time step. For example, if the event preview is executed between crank angle of 340° and 1060° (crank period is 720°) using an increment of 1°, ANSYS Fluent will report the following in the text window.

Execute Event: open-in-valve-left (defined at: 353.10, current angle: 353.00)
Execute Event: open-in-valve-right (defined at: 353.00, current angle: 353.00)
Execute Event: close-ex-valve-right (defined at: 355.60, current angle: 356.00)
Execute Event: close-ex-valve-left (defined at: 357.80, current angle: 358.00)
Execute Event: close-in-valve-left (defined at: 571.60, current angle: 572.00)
Execute Event: close-in-valve-right (defined at: 571.80, current angle: 572.00)
Execute Event: open-ex-valve-right (defined at: 137.10, current angle: 857.00)
Execute Event: open-ex-valve-left (defined at: 139.00, current angle: 859.00)

Notice that events defined at 137.10° and 139° are executed at 857° and 859°, respectively, because they satisfy the condition of Equation 10.30 (p. 644).

10.6.7.2. Defining Events for In-Cylinder Applications

ANSYS Fluent will automatically limit the valve lift values depending on the specified minimum valve lift value. However, the conversion of the sliding interface zones to walls (and vice versa) is accomplished via the in-cylinder events (see Defining Dynamic Mesh Events (p. 641)). For example, if the exhaust valve closes at −5° before TDC position, you must define a Delete Sliding Interface event at the crank angle of −5°. You must define similar events for the intake valve opening (using the Create Sliding Interface event), the intake valve closing (Delete Sliding Interface event), and the exhaust valve opening (Create Sliding Interface event) at the respective crank angles.

For the current example, the exhaust valve is assumed to be open between 131° and 371° and the intake valve is open between at 345° and 584°.
10.6.7.2.1. Events

Each of the available events is described below.

10.6.7.2.2. Changing the Zone Type

You can change the type of a zone to be a wall, or an interface, interior, fluid, or solid zone during your simulation. To change the type of a zone, select Change Zone Type in the Type drop-down list in the Define Event Dialog Box (p. 2188) (Figure 10.73: The Define Event Dialog Box (p. 643)). Select the zone(s) that you want to change in the Zone list, and then select the new zone type in the New Zone Type drop-down list.

10.6.7.2.3. Copying Zone Boundary Conditions

You can copy boundary conditions from one zone to other zones during your simulation. If, for example, you have changed an inlet zone to type wall with the Change Zone Type event, you can set the boundary conditions of the new zone type by simply copying the boundary conditions from a known zone with the corresponding zone type.

To copy boundary conditions from one zone to another, select Copy Zone BC in the Type drop-down list in the Define Event Dialog Box (p. 2188) (Figure 10.73: The Define Event Dialog Box (p. 643)). In the From Zone drop-down list, select the zone that has the conditions you want to copy. In the To Zone(s) list, select the zone or zones to which you want to copy the conditions.

ANSYS Fluent will set all of the boundary conditions for the zones selected in the To Zone(s) list to be the same as the conditions for the zone selected in the From Zone list. (You cannot copy a subset of the conditions, such as only the thermal conditions.)

Note that you cannot copy conditions from external walls to internal (that is, two-sided) walls, or vice versa, if the energy equation is being solved, since the thermal conditions for external and internal walls are different.

10.6.7.2.4. Activating a Cell Zone

To activate a cell zone, select Activate Cell Zone in the Type drop-down list in the Define Event Dialog Box (p. 2188) (Figure 10.73: The Define Event Dialog Box (p. 643)), then select the zone that you want to activate in the Zone(s) list. For more information, see Replacing, Deleting, Deactivating, and Activating Zones (p. 187).

10.6.7.2.5. Deactivating a Cell Zone

To deactivate a cell zone, select Deactivate Cell Zone in the Type drop-down list in the Define Event Dialog Box (p. 2188) (Figure 10.73: The Define Event Dialog Box (p. 643)), then select the zone that you want to deactivate in the Zone(s) list.

Only deactivated zones can be activated. When a zone is deactivated, ANSYS Fluent skips the zone during the calculations. For more information, see Replacing, Deleting, Deactivating, and Activating Zones (p. 187).

10.6.7.2.6. Creating a Sliding Interface

To create a sliding interface during your simulation, select Create Sliding Interface in the Type drop-down list in the Define Event Dialog Box (p. 2188) (Figure 10.75: The Define Event Dialog Box for the Creating Sliding Interface Option (p. 646)). Enter a name for the sliding interface in the Interface Name
field. Select the zones on either side of the interface in the **Interface Zone 1** and **Interface Zone 2** drop-down lists.

You have the option to select any number of zones listed under each of the interface zones. ANSYS Fluent calculates intersections between all possible combinations of the left and right side of the interfaces, allowing you more flexibility in terms of creating zones and defining the interfaces.

**Figure 10.75: The Define Event Dialog Box for the Creating Sliding Interface Option**

![Define Event Dialog Box](image)

**Important**

If ANSYS Fluent finds another interface with the same name as defined in the event, then the old interface will be deleted and a new one created as defined in the dynamic mesh event.

If the interface zones that you selected above do not overlap each other completely, the non-overlapped regions on each interface zones are put into separate wall zones by ANSYS Fluent. If these wall zones (that is, non-overlapped regions) have motion attributes associated with them, their motion can only be specified by copying the motion from another dynamic zone by selecting the appropriate dynamic zones in the **Wall 1 Motion** and **Wall 2 Motion** drop-down lists, respectively.

Note that you do not have to change the boundary type from wall to interface. When the **Create Sliding Interface** event is executed, ANSYS Fluent will automatically change the boundary type of the face zones selected in **Interface Zone 1** and **Interface Zone 2** to type interface before the sliding interface is created.
10.6.7.2.7. Deleting a Sliding Interface

To delete a sliding interface that has been created earlier in your simulation, select **Delete Sliding Interface** in the **Type** drop-down list in the Define Event Dialog Box (p. 2188) (Figure 10.73: The Define Event Dialog Box (p. 643)). Enter the name of the sliding interface to be deleted in the **Interface Name** field.

As with the **Create Sliding Interface** event, ANSYS Fluent will automatically change the corresponding interface zones to wall. However, you may want to use the **Copy Zone BC** event to set any boundary conditions that are not the default conditions that ANSYS Fluent assumes.

10.6.7.2.8. Changing the Motion Attribute of a Dynamic Zone

To change the motion attribute of a dynamic zone during your in-cylinder calculation, select **Change Motion Attribute** in the **Type** drop-down list in the Define Event Dialog Box (p. 2188) (Figure 10.73: The Define Event Dialog Box (p. 643)). Select the **Attribute** (smoothing or remeshing) and set the appropriate **Status** (enable or disable). Select the corresponding dynamic zones for which you want to change the motion attributes in the **Dynamic Zones** list.

The **smoothing** attribute is used to enable or disable smoothing of nodes on selected deforming face zones and the **remeshing** attribute is used to enable and disable face remeshing on selected deforming face zones.

10.6.7.2.9. Changing the Time Step

To change the time step at some point during the simulation, select **Change Time Step Size** in the **Type** drop-down list in the Define Event Dialog Box (p. 2188). Specify the new physical time step size by entering the new **Time Step Size** in seconds.

For in-cylinder simulations, specify the new physical time step by entering the new **Crank Angle Step Size** value in degrees. The physical time step is calculated from

\[ \Delta t = \frac{\Delta \theta_c}{\Omega_{shaft}} \]  

(10.31)

10.6.7.2.10. Changing the Under-Relaxation Factor

To change one or more under-relaxation factors, select **Change Under-Relaxation Factor** in the **Type** drop-down list in the Define Event Dialog Box (p. 2188) (Figure 10.73: The Define Event Dialog Box (p. 643)). Select the under-relaxation factor that you want to change, and assign a new value to it in the **Under-Relaxation Factors** list. For more information on setting under-relaxation factors, see Setting Under-Relaxation Factors (p. 1418).

10.6.7.2.11. Inserting a Boundary Zone Layer

To insert a new cell zone layer as a separate cell zone adjacent to a boundary, select **Insert Boundary Zone Layer** in the **Type** drop-down list in the Define Event Dialog Box (p. 2188). Specify the **Base Dynamic Zone**, from which the layer of cells is to be created, and the **Side Dynamic Zone**, which represents the deforming face zone adjacent to the **Base Dynamic Zone** before the layer is inserted. The new cell zone will inherit the boundary conditions of the cell zone adjacent to the **Base Dynamic Zone** before the layer is inserted.

Note that a new cell layer can be inserted only from a one-sided **Base Dynamic Zone**. You cannot insert a new cell layer from an interior face zone.
Figure 10.76: Boundary Zone Before Insertion (p. 648) and Figure 10.77: Boundary Zone After Insertion (p. 648) illustrate the insertion of a boundary zone layer. In both figures, the circular face at the top of the cylinder is the base dynamic zone.

**Figure 10.76: Boundary Zone Before Insertion**

![Boundary Zone Before Insertion](image1)

**Figure 10.77: Boundary Zone After Insertion**

![Boundary Zone After Insertion](image2)

### 10.6.7.2.12. Removing a Boundary Zone Layer

To remove the cell zone layer inserted using the Insert Boundary Zone Layer event, select Remove Boundary Zone Layer in the Type drop-down list in the Define Event Dialog Box (p. 2188). Specify the same Base Dynamic Zone that you used when you defined the insert boundary layer event.

Note that a cell layer can be removed only from a one-sided Base Dynamic Zone.

### 10.6.7.2.13. Inserting an Interior Zone Layer

To insert a new zone layer as a separate cell zone adjacent to the internal side of a boundary, select Insert Interior Zone Layer in the Type drop-down list in the Define Event Dialog Box (p. 2188). Specify the Base Dynamic Zone and the Side Dynamic Zone as described in the Insert Boundary Zone Layer event. You also must specify the names of the new interior face zones (Internal Zone 1 Name and Internal Zone 2 Name) that will be created after the cell zone layer is created by ANSYS Fluent.

ANSYS Fluent inserts the interior cell layer by splitting the cell zone adjacent to the Base Dynamic Zone with a plane. The position of the plane and the normal direction of the plane are implicitly defined by the cylinder origin and cylinder axis of the Side Dynamic Zone.

Figure 10.78: Interior Zone Before Insertion (p. 649) and Figure 10.79: Interior Zone After Insertion (p. 649) illustrate the insertion of an interior zone layer.
10.6.7.2.14. Removing an Interior Zone Layer

To remove the zone layer inserted using the Insert Interior Zone Layer event, select Remove Interior Zone Layer in the Type drop-down list in the Define Event Dialog Box (p. 2188). Specify the same Internal Zone 1 Name and Internal Zone 2 Name that you used to define the Insert Interior Zone Layer event.

10.6.7.2.15. Inserting a Cell Layer

To manually insert a new cell layer to the existing cell zone, select Insert Cell Layer in the Type drop-down list in the Define Event Dialog Box (p. 2188). Specify the Adjacent Dynamic Face Zone and the Direction Parameter. This can only work on zones that are suited for layering (see Applicability of the Dynamic Layering Method (p. 595)).

10.6.7.2.16. Removing a Cell Layer

To manually remove a cell layer from an existing cell zone, select Remove Cell Layer in the Type drop-down list in the Define Event Dialog Box (p. 2188). Specify the Adjacent Dynamic Face Zone and the
**Direction Parameter.** This can only work on zones that are suited for layering (see Applicability of the Dynamic Layering Method (p. 595)).

### 10.6.7.2.17. Executing a Command

To execute a command, select **Execute Command** in the **Type** drop-down list in the **Define Event Dialog Box** (p. 2188) (Figure 10.73: The Define Event Dialog Box (p. 643)). A command can be a series of text or Scheme commands, or a macro you have defined (or will define) using the **Define Macro Dialog Box** (p. 2265) (see Defining Macros (p. 1503)). Enter the series of commands or the name of the macro in the **Command** text-entry box.

**Important**

If the command to be executed involves saving a file, see Saving Files During the Calculation (p. 1504) for important information.

### 10.6.7.2.18. Replacing the Mesh

To replace the mesh and interpolate existing data onto the new mesh during your simulation, select **Replace Mesh** from the **Type** drop-down list in the **Define Event** dialog box (Figure 10.73: The Define Event Dialog Box (p. 643)). Then, specify the replacement mesh under **Mesh File**. Enable **Interpolate Data Across Zones** if necessary (see Replacing the Mesh (p. 191) for details).

### 10.6.7.2.19. Resetting Inert EGR

To convert burnt gases at the end of the cycle to inert for the next cycle, select **Inert EGR Reset** from the **Type** drop-down list in the **Define Event** dialog box (Figure 10.73: The Define Event Dialog Box (p. 643)). Specify the **Zone(s)**. For further details, see Resetting Inert EGR (p. 992).

### 10.6.7.2.20. Diesel Unsteady Flamelet Reset

To simulate multiple-cycle internal combustion engines using diesel unsteady flamelets, select **Diesel Unsteady Flamelet Reset** from the **Type** drop-down list in the **Define Event** dialog box (Figure 10.73: The Define Event Dialog Box (p. 643)). Specify the **Zone(s)**. This event is only applicable to and available with diesel unsteady flamelets with two or more flamelets. For further details, see Resetting Diesel Unsteady Flamelets (p. 958). Note that **Diesel Unsteady Flamelet Reset** is generally preferable to **Inert EGR Reset** since an additional transport equation is avoided.

### 10.6.7.3. Exporting and Importing Events

If you want to save the events you have defined to a file, click **Write...** in the **Dynamic Mesh Events Dialog Box** (p. 2186) and specify the **Event File** in **The Select File Dialog Box** (p. 15).

To read the events back into ANSYS Fluent, click **Read...** in the **Dynamic Mesh Events Dialog Box** (p. 2186) and specify the **Event File** in **The Select File Dialog Box** (p. 15).

### 10.6.8. Specifying the Motion of Dynamic Zones

You must define the motion of the dynamic zones in your model. If the zone is a rigid body, you can use a profile or user-defined function (UDF) to define the motion of the rigid body or use the six DOF solver. If the zone is a deforming zone, you can define the geometry and the parameters that control the face or zone remeshing, if applicable. For a zone that is deforming and moving at the same time,
you can use a user-defined function to define the geometry and motion of the zone as they change with time.

10.6.8.1. General Procedure

You will specify the motion of the dynamic zones in your model using the **Dynamic Mesh Zones** dialog box

![Dynamic Mesh → Create/Edit...](Dynamic Mesh Zones dialog box)

Details about specifying different types of motion are provided in this section.

10.6.8.1.1. Creating a Dynamic Zone

When you have completed the specification of a dynamic zone, click **Create** in the **Dynamic Mesh Zones** Dialog Box (p. 2190) to complete the specification and add the zone to the **Dynamic Mesh Zones** list.

10.6.8.1.2. Modifying a Dynamic Zone

If you want to make a change to the specification of a dynamic zone, select the zone in the **Dynamic Mesh Zones** list, change the specification, and then click **Create** in the **Dynamic Mesh Zones** Dialog Box (p. 2190) to update the specification.

10.6.8.1.3. Checking the Center of Gravity

If a dynamic zone has solid body motion, you can view its current position and orientation of the center of gravity (with respect to initial data) by selecting the zone in the **Dynamic Mesh Zones** list and viewing the values under **Center of Gravity Location** and **Center of Gravity Orientation**.

10.6.8.1.4. Deleting a Dynamic Zone

To delete a dynamic zone that you have specified, select the zone in the **Dynamic Mesh Zones** list, and click **Delete** or **Delete All**. The zone or zones will be removed from the **Dynamic Mesh Zones** list.

10.6.8.2. Stationary Zones

By default, if no motion (moving or deforming) attributes are assigned to a face or cell zone, then the zone is not considered when updating the mesh to the next time step. However, there are cases where an explicit declaration of a stationary zone is required. For example, if a cell zone is assigned some solid body motion, the positions of all nodes belonging to the cell zone will be updated even though some of the nodes may also be part of a non-moving boundary zone. An explicit declaration of a stationary zone excludes the nodes on these zones when updating the node positions.
To define a stationary zone in your model, follow the steps below.

1. Select the stationary zone in the Zone Names drop-down list.

2. Select Stationary under Type.

3. If the stationary zone is a face zone that is not a boundary of a CutCell dynamic cell zone, then define the Cell Height in the Meshing Options tab for any Adjacent Zone that is involved in local remeshing or dynamic layering. The Cell Height specifies the ideal height \( h_{\text{ideal}} \) in Equation 10.15 (p. 593) and Equation 10.16 (p. 594) of the adjacent cells. Make a selection in the Cell Height drop-down menu to specify this value as either a constant or a compiled user-defined function.

   If you select the constant option, enter a value in the Cell Height text-entry box.

   If you choose to use a compiled user-defined function to define an ideal cell height that varies as a function of time or crank angle, you must first define a `DEFINE_DYNAMIC_ZONE_PROPERTY` UDF. After you have compiled the UDF source file, built a shared library, and loaded it into ANSYS Fluent, the name of the UDF library will be available for selection in the Cell Height drop-down list.

   Refer to the UDF Manual for information about UDFs.

4. If the stationary zone is a boundary of a CutCell dynamic cell zone (this is automatically detected if the CutCell dynamic cell zone is created first), then enter values for the Maximum Mesh Size and Growth Rate in the Meshing Options tab. If you have enabled Inflation Layers for the cell zone, then you will also have the option to enable Zonal Inflation Layer Control on the boundary zone and specify local
inflation settings in the **Inflation Settings** dialog box (using the **Settings...** button). See Figure 10.81: The Dynamic Mesh Zones Dialog Box for a CutCell Boundary Zone (p. 654) for an example of the **Dynamic Mesh Zones** dialog box with the **Meshing Options** tab as it appears for CutCell boundary zones. (The same meshing input is required at all CutCell boundary zones, whether the motion type is **Stationary**, **Rigid Body**, **Deforming**, or **User-Defined**.)

Two different size functions are available to control the local mesh refinement:

- **soft size function**

  For this size function, the Cartesian mesh is locally refined such that the resulting mesh size is smaller or equal to the **Maximum Mesh Size** specified.

- **mesh-based size function**

  For this size function, the Cartesian mesh is locally refined such that the resulting mesh size is locally of the same size as the input mesh provided.

The switch between using the soft or the mesh-based size function depends on the value entered for the **Maximum Mesh Size**. A value of 0 specifies that the mesh-based size function is used. If a positive value is entered, then the soft size-function is used and the value entered locally limits the mesh size. The **Growth Rate** controls the rate at which the Cartesian mesh grows away from the boundary. The maximum Cartesian mesh size obtained in the cell zone is always controlled by the specified **Maximum Mesh Size** for the CutCell cell zone.
You can view the vital statistics of your zone by clicking on the Zone Scale Info... button. This opens the Zone Scale Info Dialog Box (p. 2198), where you can view the minimum, maximum, and average length scale values, as well as the maximum skewness value.

5. Click Create.

Note that if you specify inflation layer parameters in the Inflation Settings dialog box, these settings are not saved until you create or update the dynamic zone.

### 10.6.8.3. Rigid Body Motion

To define a rigid-body zone in your model, follow the steps below.
1. Select the rigid body zone in the **Zone Names** drop-down list.

2. Select the **Rigid Body** option under **Type**.

3. If you want to specify the motion of the rigid body zone using a profile or user-defined function, then select a profile or user-defined function from the **Motion UDF/Profile** drop-down list in the **Motion Attributes** tab. See **Profiles** (p. 377) and **Solid-Body Kinematics** (p. 664) for information on profiles, and see the **UDF Manual** for information on user-defined functions.

4. If you selected the **In-Cylinder** option in the **Dynamic Mesh Task Page** (p. 2175), ANSYS Fluent provides built-in functions in the **Motion UDF/Profile** drop-down list that can be useful for defining the rigid body motion of a piston. If you would like the motion of the piston to be a function of crank angle (that is, governed by **Equation 10.25** (p. 623)), then you should select **piston-full**. For further information, see **In-Cylinder Settings** (p. 621).

5. If you want to use the **Six DOF** solver option, then select the appropriate UDF from the **Six DOF UDF** drop-down list in the **Motion Attributes** tab (see **Figure 10.83: The Dynamic Mesh Zones Dialog Box for a Rigid Body Motion Using the Six DOF Solver** (p. 656)). Note that you should make sure that **On** is enabled under **Six DOF Options** to ensure that the Six DOF solver is being used. See the **UDF Manual** for information on user-defined functions. For more information about the six DOF solver, see **Using the Six DOF Solver** (p. 637).

   Note that the **Passive** option under **Six DOF Options** is used when you do not want the forces and moments on the zone to be taken into consideration.
6. Specify the initial location of the center of gravity for the rigid body by entering the coordinates of the center of gravity in **Center of Gravity Location**.

7. Specify the orientation of the object with respect to the center of gravity (in the inertia coordinate system) by entering the orientations of the center of gravity in **Center of Gravity Orientation**.

For most cases, this is an initial reference orientation that ANSYS Fluent later updates, letting you keep track of the object's current orientation. The center of gravity orientation is most useful when using the Six DOF solver, where it is used to compute the transformation matrices (*Six DOF (6DOF) Solver Theory* in the Theory Guide).

8. When using the Six DOF solver, specify the velocity of the center of gravity with respect to the inertia coordinate system by entering the velocity of the center of gravity in **Center of Gravity Velocity**. Also, specify the angular velocity of the center of gravity with respect to the inertia coordinate system by entering the angular velocity of the center of gravity in **Center of Gravity Angular Velocity**.

**Figure 10.83: The Dynamic Mesh Zones Dialog Box for a Rigid Body Motion Using the Six DOF Solver**
9. If you are solving an in-cylinder problem, specify the direction of the reference axis of the valves or piston in **Valve/Piston Axis**.

The current valve lift or piston stroke is automatically updated in **Lift/Stroke** when you click **Create** based on the parameters you have specified earlier when you first invoke the in-cylinder option.

10. By default, the boundary mesh motion is taken into consideration when imposing the physical boundary conditions, even if the boundary moves because of a moving adjacent cell zone and no dynamic zone has been created for the boundary. If this is not the desired behavior, and if you would like to exclude the mesh motion from contributing to the boundary conditions, then you need to enable the **Exclude Mesh Motion in Boundary Conditions** option for that zone.

11. If the rigid body zone is a face zone that is not a boundary of a CutCell dynamic cell zone, specify the **Cell Height** for each **Adjacent Zone** in the **Meshing Options** tab. The **Cell Height** is the ideal cell height \( h_{\text{ideal}} \) in Equation 10.15 (p. 593) and Equation 10.16 (p. 594) that is used by ANSYS Fluent to determine when the prismatic layer next to the rigid body should be split or merged with the layer next to it. If the adjacent zone is tetrahedral or triangular, the ideal height is used by ANSYS Fluent to determine if adjacent cells must be agglomerated for local remeshing. Make a selection in the **Cell Height** drop-down menu to specify this value as either a **constant** or a compiled user-defined function.

If you select the **constant** option, enter a value in the **Cell Height** text-entry box.

If you choose to use a compiled user-defined function to define an ideal cell height that varies as a function of time or crank angle, you must first define a **DEFINE_DYNAMIC_ZONEPROPERTY** UDF. After you have compiled the UDF source file, built a shared library, and loaded it into ANSYS Fluent, the name of the UDF library will be available for selection in the **Cell Height** drop-down list.

Refer to the **UDF Manual** for information about UDFs.

12. If the rigid body zone is a boundary of a CutCell dynamic cell zone (this is automatically detected if the CutCell dynamic cell zone is created first), then enter values for the **Maximum Mesh Size** and **Growth Rate** in the **Meshing Options** tab, as described in step 4 of **Stationary Zones** (p. 651). If you have enabled **Inflation Layers** for the cell zone, then you will also have the option to enable **Zonal Inflation Layer Control** on the boundary zone and specify local inflation settings in the **Inflation Settings** dialog box (using the **Settings...** button).

13. If the dynamic zone is a face zone with an adjacent boundary layer mesh, you must apply boundary layer smoothing using the **Deform Adjacent Boundary Layer with Zone** option in the **Meshing Options** tab if you want the boundary layer to move with the moving face zone. For example, this option is necessary if you are applying face region remeshing with prism layers and you have not decomposed the mesh volume (see **Face Region Remeshing with Wedge Cells in Prism Layers** (p. 609)). In such circumstances, the **Deform Adjacent Boundary Layer with Zone** option ensures that the base prism elements shown in **Figure 10.43: Volume Decomposition for the Base of the Prism Layers** (p. 611) will move rigidly with the piston.

Note that the boundary layer smoothing method is primarily intended for translational motion of the face zone. If significant rotation is applied to the face zone, the boundary layer cells may become skewed. For more information refer to **Boundary Layer Smoothing Method** (p. 589).

14. Click **Create**.

**10.6.8.4. Deforming Motion**

To define a deforming zone in your model, follow the steps below.
1. Select the deforming zone in the **Zone Names** drop-down list.

2. Select the **Deforming** option under **Type**.

3. Specify the geometry of the deforming zone in the **Geometry Definition** tab.
   - If no geometry is available, select **faceted** in the **Definition** drop-down list.
   - If the geometry is a plane, select **plane** in the **Definition** drop-down list. To define the plane, enter the position of a point on the plane in **Point on Plane** and the plane normal in **Plane Normal**.
   - If the geometry is a cylinder, select **cylinder** in the **Definition** drop-down list. To define the cylinder, enter the **Cylinder Radius**, the **Cylinder Origin** and the **Cylinder Axis**.
   - If the geometry is unspecified and mesh motion normal to the boundary is permissible, select **unspecified** in the **Definition** drop-down list. This option is only available if the linearly elastic solid mesh smoothing method is enabled (Linearly Elastic Solid Based Smoothing Method (p. 587)).
• If the geometry is described by a user-defined function, select user-defined in the Definition drop-down list and the appropriate user-defined functions in the Geometry UDF drop-down list. See the UDF Manual for information on user-defined functions.

For 3D simulations, ANSYS Fluent allows you to preserve features not only between the different face zones, but also within a face zone. For any geometry definition (faceted, plane, cylinder, or user-defined), you can indicate whether you want to include features of a specific angle by selecting Include Features under Feature Detection and setting the Feature Angle in degrees. For more information, see Feature Detection (p. 619).

When available, the geometry information is used to project nodes on the deforming zone after remeshing the face zone, or if nodes are moved through smoothing.

4. For deforming face and cell zones that are not CutCell zones, specify the appropriate remeshing parameters in the Meshing Options tab.

You can locally disable or enable Smoothing and or Remeshing and use any Smoothing and or Remeshing method.

You can view the vital statistics of your zone by clicking the Zone Scale Info... button. This opens the Zone Scale Info Dialog Box (p. 2198), where you can view the minimum and maximum length scale values, as well as the maximum skewness values.

If you selected a cell or face zone, you must enter Minimum Length Scale, Maximum Length Scale and Maximum Skewness if you want impose a different set of remeshing criteria, other than those you specified globally in the Dynamic Mesh Task Page (p. 2175). This is not required for cell zones since the global settings for the dynamic mesh parameters are used if ANSYS Fluent determines that the local settings are unreasonable. You should use the information found in the Zone Scale Info Dialog Box (p. 2198) in order to set your values.

If spring-based smoothing is used and you selected a cell zone, then you have the option to overwrite the element type selection made in the Mesh Method Settings dialog box (see Figure 10.14: The Smoothing Tab of the Mesh Method Settings Dialog Box (3D) (p. 577)). Select Global Settings if no zone specific smoothing element type is desired.

5. To specify that a deforming cell zone is remeshed using the CutCell zone method, enable the CutCell option in the Remeshing Options group box of the Meshing Options tab (see Figure 10.85: The Dynamic Mesh Zones Dialog Box for a Deforming CutCell Cell Zone (p. 660)). Note that this option is only available if you have previously enabled the CutCell Zone option in the Remeshing tab of the Mesh Method Settings dialog box (see Figure 10.33: The Remeshing Tab in the Mesh Method Settings Dialog Box (p. 598)).
After the **CutCell** option has been enabled, you must enter values for the global CutCell parameters **Maximum Mesh Size** and **Growth Rate**, as well as the controls for the remeshing frequency, **Minimum Orthogonal Quality** and **Remeshing Interval**. You also have the option to enable **Inflation Layers** for the cell zone and specify the global inflation parameters in the **Inflation Settings** dialog box. See **Using the CutCell Zone Remeshing Method** (p. 614) for more information about adding inflation layers to a CutCell mesh.

The **Maximum Mesh Size** specified for the CutCell cell zone controls the global maximum size of the Cartesian cells. The global **Growth Rate** is used for all mesh-based size functions applied to CutCell boundary zones that are not defined as dynamic zones. When selecting values for these controls, it may be helpful to view the statistics of your cell zone by clicking on the **Zone Scale Info...** button. This opens the **Zone Scale Info Dialog Box** (p. 2198), where you can view the minimum and maximum length scale values, as well as the maximum skewness values.

The CutCell remeshing is performed automatically whenever cells exhibit an orthogonal quality (as defined in **Mesh Quality** (p. 129)) that is less than the specified **Minimum Orthogonal Quality**.
remeshing is also performed periodically after the calculation has undergone the number of time steps you specified for the Remeshing Interval.

Click the Boundary Zones Info... button to open the CutCell Boundary Zones Info dialog box (Figure 10.86: The CutCell Boundary Zones Info Dialog Box (p. 661)). This dialog box lists all the boundary zones associated with the CutCell cell zone, along with the associated size functions and zonal meshing parameters. The inflation layer settings used on all boundaries are also shown. It is recommended that you revisit this dialog box after you have created all of the dynamic zones, in order to review all of the parameters you have set.

**Figure 10.86: The CutCell Boundary Zones Info Dialog Box**

6. If the deforming zone is a boundary of a CutCell dynamic cell zone (this is automatically detected if the CutCell dynamic cell zone is created first), then enter values for the Maximum Mesh Size and Growth Rate in the Meshing Options tab, as described in step 4 of Stationary Zones (p. 651). If you have enabled Inflation Layers for the cell zone, then you will also have the option to enable Zonal Inflation Layer Control on the boundary zone and specify local inflation settings in the Inflation Settings dialog box (using the Settings... button).

7. Click Create.

**10.6.8.5. User-Defined Motion**

For a zone that is deforming and moving, you can define the position of each node on the general deforming/moving zone using a user-defined function (UDF). To define a moving and deforming zone, follow the steps below.

1. Select the moving and deforming zone in the Zone Names drop-down list.

2. Select the User-Defined option under Type.

3. In the Motion Attributes tab, select the user-defined function that defines the geometry and motion of the zone from the Mesh Motion UDF drop-down list. See the UDF Manual for information on user-defined functions used to specify user-defined motion.

4. By default, the boundary mesh motion is taken into consideration when imposing the physical boundary conditions, even if the boundary moves because of a moving adjacent cell zone and no dynamic zone
has been created for the boundary. If this is not the desired behavior, and if you would like to exclude the mesh motion from contributing to the boundary conditions, then you need to enable the **Exclude Mesh Motion in Boundary Conditions** option for that zone.

5. For a face zone that is not a boundary of a CutCell dynamic cell zone, you can specify the **Cell Height** in the **Meshing Options** tab for any **Adjacent Zone** that is involved in local remeshing or dynamic layering. The **Cell Height** specifies the ideal height \( h_{\text{ideal}} \) in **Equation 10.15** (p. 593) and **Equation 10.16** (p. 594) of the adjacent cells. Make a selection in the **Cell Height** drop-down menu to specify this value as either a **constant** or a compiled user-defined function.

If you select the **constant** option, enter a value in the **Cell Height** text-entry box.

If you choose to use a compiled user-defined function to define an ideal cell height that varies as a function of time or crank angle, you must first define a **DEFINE_DYNAMIC_ZONE_PROPERTY** UDF. After you have compiled the UDF source file, built a shared library, and loaded it into ANSYS Fluent, the name of the UDF library will be available for selection in the **Cell Height** drop-down list.

Refer to the separate **UDF Manual** for information about UDFs.

6. If the face zone is a boundary of a CutCell dynamic cell zone (this is automatically detected if the CutCell dynamic cell zone is created first), then enter values for the **Maximum Mesh Size** and **Growth Rate** in the **Meshing Options** tab, as described in step 4 of **Stationary Zones** (p. 651). If you have enabled **Inflation Layers** for the cell zone, then you will also have the option to enable **Zonal Inflation Layer Control** on the boundary zone and specify local inflation settings in the **Inflation Settings** dialog box (using the **Settings...** button).

7. If the dynamic zone is a face zone with an adjacent boundary layer mesh, and you want to use the boundary layer smoothing method (as described in **Boundary Layer Smoothing Method** (p. 589)), enable the **Deform Adjacent Boundary Layer with Zone** option in the **Meshing Options** tab.

8. Click **Create**.

### 10.6.8.5.1. Specifying Boundary Layer Deformation Smoothing

For a boundary layer that deforms according to the adjacent face zone, the zone that is deforming and moving is usually defined using a user-defined function (UDF), as described in **User-Defined Motion** (p. 661). To define a moving and deforming boundary layer, perform the steps that follow.

If the boundary layer borders a face zone that is only moving and is not deforming, you should consider applying rigid body motion to the face zone (see **Rigid Body Motion** (p. 654)) rather than user-defined motion, as rigid body motion usually involves a simpler UDF.

1. Set up the moving and deforming zone.
   a. Select the moving and deforming zone in the **Zone Names** drop-down list.
   b. Select the **User-Defined** option under **Type**.
   c. In the **Motion Attributes** tab, select the user-defined function that defines the geometry and motion of the zone from the **Mesh Motion UDF** drop-down list.
   d. In the **Meshing Options** tab, enable the **Deform Adjacent Boundary Layer with Zone** option.
   e. Click **Create**.
2. Set up a deforming dynamic zone for the fluid zone that contains the boundary layer.
   a. Select the fluid zone that contains the boundary layer from the Zone Names drop-down list.
   b. Select Deforming from Type list.
   c. In the Meshing Options tab, enable Smoothing and Remeshing in the Methods group box.
   d. Click Create.

3. If the fluid zone set up in the step 2 consists entirely of the boundary layer elements, set up a deforming dynamic zone for the neighboring fluid zone. This step is necessary because the deforming boundary layer will deform the adjacent cells.
   a. Select the fluid zone that neighbors the boundary layer zone from the Zone Names drop-down list.
   b. Select Deforming from Type list.
   c. In the Meshing Options tab, enable Smoothing and Remeshing in the Methods group box.
   d. Click Create.

10.6.8.6. System Coupling Motion

For a zone that is involved in a system coupling, the motion is defined by the application that ANSYS Fluent is coupled with on this zone. For more details about setting up a simulation with system coupling see the Fluent in Workbench User’s Guide and the System Coupling Guide. To define a system coupling region, follow the steps below.

1. Select the moving and deforming zone in the Zone Names drop-down list.

2. Select the System Coupling option under Type.

3. The system coupling region cannot be a boundary of a CutCell dynamic cell zone, so you can specify the Cell Height in the Meshing Options tab for any Adjacent Zone that is involved in local remeshing or dynamic layering. The Cell Height specifies the ideal height \( h_{\text{ideal}} \) in Equation 10.15 (p. 593) and Equation 10.16 (p. 594) of the adjacent cells. Make a selection in the Cell Height drop-down menu to specify this value as either a constant or a compiled user-defined function.

   If you select the constant option, enter a value in the Cell Height text-entry box.

   If you choose to use a compiled user-defined function to define an ideal cell height that varies as a function of time or crank angle, you must first define a DEFINE_DYNAMIC_ZONE_PROPERTY UDF. After you have compiled the UDF source file, built a shared library, and loaded it into ANSYS Fluent, the name of the UDF library will be available for selection in the Cell Height drop-down list.

   Refer to the separate UDF Manual for information about UDFs.

4. Solution stabilization may be necessary to achieve convergence for system coupling cases where there is a strong coupling. Stabilization is achieved through a boundary source coefficient introduced in the continuity equation, designed to improve the diagonal dominance of the matrix system in the cells adjacent to system coupling boundaries. Two methods for this boundary source coefficient are available:
• volume-based

This method uses the cell volume $V$ to re-scale the diagonal entry of the linear matrix system corresponding to the discretized continuity equation ($a_{ij}$) as $a_{ij,s}$:

$$a_{ij,s} = a_{ij} + KV \quad \text{if } i = j \forall i,j \in \{1,2,\ldots,n\}$$  \hspace{1cm} (10.32)

• coefficient-based

This method directly re-scales the diagonal entry of the linear matrix system corresponding to the discretized continuity equation ($a_{ij}$) as $a_{ij,s}$:

$$a_{ij,s} = a_{ij} + K a_{ij} \quad \text{if } i = j \forall i,j \in \{1,2,\ldots,n\}$$  \hspace{1cm} (10.33)

where $K$ is the scale factor and $n$ is the number of cells. Note that the value you choose for $K$ will only affect the rate of convergence, and will not affect the converged solution.

Solution stabilization options for the system coupling region can be set by opening the Solver Options tab, selecting the Solution Stabilization check box, and then specifying the appropriate options under Stabilization Parameters. Available options include the Scale Factor (0 is the default) and the Method, which can be either volume-based (default) or coefficient-based.

These options can also be set using the text user interface commands for the system coupling region type, and solver option settings for each dynamic zone are visible when you use the list command.

5. Click Create.

**Note**

If the System Coupling option is enabled, and ANSYS Fluent is not involved with a system coupling simulation, then this zone type behaves in the same way as a stationary zone.

### 10.6.8.7. Solid-Body Kinematics

ANSYS Fluent uses solid-body kinematics if the motion is prescribed based on the position and orientation of the center of gravity of a moving object. This is applicable to both cell and face zones.

The motion of the solid-body can be specified either as a profile or as a user-defined function (UDF). A profile may be defined by the following profile fields:

• time (time)
• crank angle (angle) (in-cylinder flows only)
• position ($x$, $y$, $z$)
• linear velocity ($v_x$, $v_y$, $v_z$)
• angular velocity ($\omega_x$, $\omega_y$, $\omega_z$)
• orientation ($\theta_x$, $\theta_y$, $\theta_z$)
For in-cylinder simulations, the velocity profiles for valves can be expressed as a function of crank angle instead of time. In addition, transient boundary condition profiles can also be expressed as a function of crank angle instead of time. For more information about transient profiles, see Defining Transient Cell Zone and Boundary Conditions (p. 388).

Below are two examples of a profile format:

((movement_linear 3 point)
 (time
  0  1  2 )
 (x
  2  3  4 )
 (v_y
  0  -5  0 )
 )

((movement_angular 3 point)
 (time
  0  1  2 )
 (omega_x
  2  3  4 )
 )

For in-cylinder flows, crank angles can be included in transient tables as well as transient profiles, in a similar fashion to time. An example of a transient table using (crank) angle is as follows:

example 2 3 1
angle temperature
0  300
180 500
360 300

An example of a transient profile using (crank) angle is as follows:

((example transient 3 l)
 (angle
  0.000000e+00 1.800000e+02 3.600000e+02
  3.000000e+02 5.000000e+02 3.000000e+02
 )

In addition to the motion description, you must also specify the starting location of the center of gravity and orientation of the solid body. In 2D cases (and 3D cases that do not use the six DOF solver), ANSYS Fluent automatically updates the center of gravity position and orientation at every time step such that

\[
\begin{align*}
\bar{x}_{c.g.}^{n+1} &= \bar{x}_{c.g.}^n + \bar{v}_{c.g.} \Delta t \\
\bar{\theta}_{c.g.}^{n+1} &= \bar{\theta}_{c.g.}^n + \bar{Q}_{c.g.} \Delta t
\end{align*}
\]  (10.34)

where \( \bar{x}_{c.g.} \) and \( \bar{\theta}_{c.g.} \) are the position and orientation of the center of gravity, \( \bar{v}_{c.g.} \) and \( \bar{Q}_{c.g.} \) are the linear and angular velocities of the center of gravity. 3D, six DOF cases use a more complex form of Equation 10.34 (p. 665) when updating \( \bar{\theta} \).

Typically, \( \bar{\theta} \) is chosen to be an appropriate set of Euler angles. In this case, the solid-body motion must be specified using a user-defined function \( \text{DEFINE}_\text{CG}_\text{MOOTION} \).
The position vectors on the solid body are updated based on rotation about the instantaneous angular velocity vector $\vec{\Omega}_{c.g.}$. For a finite rotation angle $\Delta \theta = |\vec{\Omega}_{c.g.}| \Delta t$, the final position of a vector $\vec{x}_r$ on the solid body with respect to $\vec{x}_{c.g.}$ can be expressed as (See Figure 10.87: Solid Body Rotation Coordinates (p. 666))

$$\vec{x}^{n+1}_r = \vec{x}^n_r + \Delta \vec{x}$$  \hspace{1cm} (10.35)

where $\Delta \vec{x}$ can be shown to be

$$\Delta \vec{x} = \vec{x}^n_r - \vec{x}_{c.g.} - [\sin(\Delta \theta) \hat{e}_\theta + (\cos(\Delta \theta) - 1) \hat{e}_r]$$  \hspace{1cm} (10.36)

The unit vectors $\hat{e}_\theta$ and $\hat{e}_r$ are defined as

$$\hat{e}_\theta = \frac{\vec{\Omega}_{c.g.} \times \vec{x}_r}{|\vec{\Omega}_{c.g.} \times \vec{x}_r|}$$  \hspace{1cm} (10.37)

$$\hat{e}_r = \frac{\hat{e}_\theta \times \vec{\Omega}_{c.g.}}{|\hat{e}_\theta \times \vec{\Omega}_{c.g.}|}$$  \hspace{1cm} (10.38)

If the solid body is also translating with $\vec{V}_{c.g.}$, the $n+1$ position vector on the solid body can be expressed as

$$\vec{x}^{n+1} = \vec{x}^n_{c.g.} + \vec{V}_{c.g.} \Delta t + \vec{x}^{n+1}_r$$  \hspace{1cm} (10.39)
where \( \tilde{x}_{r}^{n} \) is given by Equation 10.35 (p. 666).

### 10.6.9. Previewing the Dynamic Mesh

When you have specified the mesh update methods and their associated parameters, and you have defined the motion of dynamic zones, as described in Specifying the Motion of Dynamic Zones (p. 650), you can preview the motion of the mesh or the zone as it changes with time before you start your simulation. The same dynamic zone or mesh motion will be executed when you start your simulation.

#### 10.6.9.1. Previewing Zone Motion

You can preview the motion of zones with Rigid Body or User-Defined motion using the Zone Motion Dialog Box (p. 2199) (Figure 10.88: The Zone Motion Dialog Box (p. 667)).

![Dynamic Mesh ➔ Display Zone Motion...](image)

**Figure 10.88: The Zone Motion Dialog Box**

The zone motion preview only updates the graphical representation (in the graphics window) of the zones that you have selected in the Dynamic Face Zones list. Only zones that have been specified with either User-Defined or Rigid Body motion type are available for zone motion preview. To use the Zone Motion preview:

1. In the Zone Motion Dialog Box (p. 2199), select the face zones for which you want to preview the motion from the Dynamic Face Zones list. The Dynamic Face Zones list displays zones that have either User-Defined or Rigid Body motion specified. By default, all such zones are selected.

2. Enter the Start Time, Time Step, and Number of Steps under Time Control.

3. Click the Preview button to preview the zone motion. This positions the mesh according to the specified Start Time, and then integrates the position of the selected surfaces in time. The zone positions at the specified Start Time can be previewed without any subsequent motion by entering 0 for the Number of Steps.

4. Click Reset to restore the mesh to its initial state.
Previewing the zone motion can also be used as a postprocessor for six DOF simulations (see Using the Six DOF Solver (p. 637)).

### 10.6.9.2. Previewing Mesh Motion

The mesh motion preview is different from the zone motion described above in that the mesh connectivity is changed in mesh motion.

To preview the dynamic mesh of a transient case, you can use the Mesh Motion Dialog Box (p. 2200) (Figure 10.89: The Mesh Motion Dialog Box (p. 668))

![Dynamic Mesh → Preview Mesh Motion...](image)

**Figure 10.89: The Mesh Motion Dialog Box**

The procedure is as follows:

1. Save the case file.
   
   File → Write → **Case**...

   **Important**

   Note that the mesh motion will actually update the node locations as well as the connectivity of the mesh, so you must be sure to save your case file before doing the dynamic mesh motion. Once you have advanced the mesh by a certain number of time steps, you will not be able to recover the previous status of the mesh, other than by reloading the appropriate ANSYS Fluent case file.

2. Specify the **Number of Time Steps** and the size of each time step (**Time Step Size**). The current time will be displayed in the **Current Mesh Time** field after the dynamic mesh has been advanced the specified number of steps.

   Note that if you turned on the in-cylinder option, the **Time Step Size** is automatically calculated from the **Crank Angle Step Size** and the **Crank Shaft Speed** that you have specified in the **In-Cylinder** tab of the Options Dialog Box (p. 2181).

3. To view the dynamic mesh in the graphics window, enable the **Display Mesh** option. In addition, you can control the frequency at which ANSYS Fluent should display an updated mesh in the **Display Fre-
4. Turn on **Enable Autosave** to use the automatic saving feature to specify the file name and frequency with which case and data files should be saved during the solution process. This opens the **Autosave Case During Mesh Motion Preview Dialog Box** (p. 2201).

See **Automatic Saving of Case and Data Files** (p. 49) for details about the use of this feature. This provides a convenient way for you to save results at successive time steps for later postprocessing.

5. Enable the **Update Mesh Interfaces** option to update the interface at every time step.

6. Use the **Update Monitors** option to disable the processing of monitors and computation activities during mesh motion preview. This allows you to set up monitors and computational activities before running mesh motion preview without creating monitor files during the mesh motion preview.

7. Click **Preview** to start the preview. ANSYS Fluent will update the dynamic mesh by moving and deforming the face and cell zones that you have specified as dynamic zones. Click **Apply** to save your settings for mesh motion.

During the preview, information about the dynamic mesh will be displayed in the console window for each time step. Note that for the in-cylinder option, the reported **Maximum Cell Skew** is calculated only from zones undergoing remeshing. This ensures that you can always ascertain whether the skewness is increasing in the deforming zones. To report the maximum skewness of a cell from any zone, you can click the **Report Quality** button in the **General Task Page** (p. 1888).

**General → Report Quality**

### 10.6.10. Steady-State Dynamic Mesh Applications

While many dynamic mesh problems are transient, you can use dynamic meshes for steady-state applications as well. Some examples of steady-state applications include: checking the valve application after reaching a steady-state valve position; or after a fluid-structure interface application has reached a steady-state solution.

There are no differences in the meshing aspect between steady-state cases and transient cases. Furthermore, setting up a steady-state simulation is similar to setting up a transient case, described in **Using Dynamic Meshes** (p. 573). However, there are a few differences that you should note:

- A **CG_MOTION** UDF is needed to specify the motion of the boundary: a transient profile used in transient cases cannot be used in steady-state cases.

- The **dt** passed to the **CG_MOTION** UDF is 1 by default: if a displacement of 1 mm is needed to move the boundary, you can specify the velocity to be 1e-3 m/s.

- Dynamic mesh parameters can be different since an interpolation error is no longer a concern.

- If you have enabled local remeshing for your steady-state application, you can instruct ANSYS Fluent to perform additional remeshing after the boundary has moved. This additional remeshing is based on skewness criteria, and can further increase the quality of your mesh. See **Dynamic Mesh Update Methods** (p. 576) for further details.
The mesh must be manually updated through journal files or execute commands. To update the mesh, you can use the Mesh Motion Dialog Box (p. 2200).

Run Calculation ➔ Preview Mesh Motion...

Alternatively, you can use the following text command:

```
solve ➔ mesh-motion
```

which can also be used as an execute command in the Execute Commands Dialog Box (p. 2264):

Calculation Activities ➔ Create/Edit... (Execute Commands)

You can display dynamic mesh statistics (such as minimum and maximum volumes and maximum cell and face skewness) by clicking the Update button in the Mesh Motion Dialog Box (p. 2200) (Figure 10.90: The Mesh Motion Dialog Box for Steady-State Dynamic Meshes (p. 670)).

**Figure 10.90: The Mesh Motion Dialog Box for Steady-State Dynamic Meshes**

![Mesh Motion Dialog Box](image)

---

Important

The following options are not available for steady-state applications:

- In-Cylinder
- Six DOF
- Implicit Update

Also, the Dynamic Mesh Events dialog box is not available for steady-state applications.

---

10.6.10.1. An Example of Steady-State Dynamic Mesh Usage

Consider a rescue drop case shown in Figure 10.91: Initial Object Position (p. 671). The object can be moved in any position in the steady-state solver, after which steady-state analyses can be performed at different object positions.
The dynamic mesh parameters setup is identical for the steady-state and transient cases, which is described in Setting Dynamic Mesh Modeling Parameters (p. 575). When setting up the dynamic zones, the procedures are similar to those described in Specifying the Motion of Dynamic Zones (p. 650), except that the UDF selected from the Motion UDF/Profile drop-down list is different. In steady-state cases the dtime passed to the UDF is by default 1. So, in this example, the object will move 50 mm each time the following UDF is executed:

```c
#include "udf.h"

DEFINE_CG_MOTION(pod,dt,vel,omega,time,dtime)
{
  NV_S(vel,=,0);
  NV_S(omega,=,0);
  vel[1] = -50e-3;
}
```

The resulting mesh is shown in Figure 10.93: Final Object Position After 40 Executions (p. 672).
Figure 10.93: Final Object Position After 40 Executions
Chapter 11: Modeling Flows Using the Mesh Morpher/Optimizer

This chapter describes the setup and use of the mesh morpher/optimizer in ANSYS Fluent.

Details about the mesh morpher/optimizer are presented in the following sections:

11.1. Introduction
11.2. The Optimization Process
11.3. Optimizers
11.4. Setting Up the Mesh Morpher/Optimizer

11.1. Introduction

Shape optimization has increasingly become a critical field in the area of CFD. ANSYS Fluent provides a mesh morphing capability that allows you to solve shape optimization problems [40] (p. 2559). This capability is suitable for problems that require minimal design changes in the geometry in order to satisfy certain criteria. The target criteria can be specified in the form of an objective function to be minimized through optimization routines. For example, you could optimize the shape of a car for reduced drag. As another example, you could specify a more complex objective function to minimize the drag/lift ratio of an airfoil.

The mesh morpher/optimizer in ANSYS Fluent has the following advantages:

• The optimization problem can be solved inside ANSYS Fluent. You can maintain the topology of the initial design, while generating solutions for desired configurations without having to go back and change the geometry and mesh it again.

• The mesh morpher can handle multiple deformation regions.

For additional information, see the following section:

11.1.1. Limitations

11.1.1. Limitations

Note the following limitations of the ANSYS Fluent mesh morpher/optimizer:

• Arbitrarily shaped deformation regions are not supported.

• If the surface to surface (S2S) radiation model is enabled, the view factors will need to be recomputed at the very least when the optimization is complete. If the objective function is a function of temperature, the view factors will need to be recomputed after each design change.

• The mesh morpher/optimizer should not be used with dynamic or sliding mesh problems.

11.2. The Optimization Process

All optimization problems require that you identify parameters that can be modified in order to reach the optimized solution. In the case of the mesh morpher/optimizer, it is the geometry that must be parameterized. Geometric parameterization for general shapes used in CFD can be very complicated,
due to the large variety of shapes available in engineering applications. In order to minimize such complications in your ANSYS Fluent simulation, the problem of shape parameterization is reduced to a problem of the parameterization of changes in the geometry.

The next essential requirement for mesh morphing is a tool that can smoothly alter the shape, irrespective of the underlying mesh topology. In ANSYS Fluent, this is accomplished using a free form deformation technique. This technique manipulates designated deformation regions via displacements applied to a set of control points. The mesh region that is to be deformed is overlaid with a "box" (that is, a rectangle for 2D cases and a rectangular hexahedron for 3D) comprised of a specified number of uniformly-distributed control points in global coordinates. Each parametric change to the geometry is defined by a set of user-specified scaling factors. These scaling factors specify the displacement of each control point for a unit change in the parameter value. The resulting displacements are applied to the mesh as a smooth deformation by using the tensor product of Bernstein polynomials.

The next requirement is to have an optimizer that is robust enough to handle a wide range of problems. By coupling such optimizers with your CFD analysis, you can greatly improve your design with minimal intervention. You can use built-in optimizers to vary the parameter values along the directions of the defined scaling factors and within defined bounds, in order to satisfy a condition specified by an objective function. The mesh morpher/optimizer provides you with access to six optimizers that are not based on gradients. Otherwise, you can manually specify the deformation (that is, define both the parameter values and the scaling factors) and analyze the results; you also have the option of using Design Exploration in ANSYS Workbench to easily explore the impact of a variety of parameter values.

11.3. Optimizers

The built-in optimizers used as part of the mesh morpher/optimizer capability in ANSYS Fluent use direct search methods for optimization. Direct search methods are zeroth order, as they only use the objective function values for optimization. The direct search methods do not use the derivatives.

The following is a list of advantages of direct search methods:

- Direct search methods do not require derivatives for optimization.
- Direct search methods are robust for problems with discontinuities and in situations where the derivative computation is not possible or unreliable.

The following is a list of disadvantages of direct search methods:

- Convergence proof is not clearly defined.
- The rate of convergence can be very slow.

General explanations of the six different built-in optimizers are provided in the following sections:

11.3.1. The Compass Optimizer
11.3.2. The NEWUOA Optimizer
11.3.3. The Simplex Optimizer
11.3.4. The Torczon Optimizer
11.3.5. The Powell Optimizer
11.3.6. The Rosenbrock Optimizer

11.3.1. The Compass Optimizer

In the Compass optimizer [45 (p. 2559)], the parameters are adjusted one by one until the objective function is minimized. This optimizer starts with a given value and then evaluates the function value
in all the basic directions. The direction here refers to the positive and negative increments to the initial parameter values. If there is a reduction in the function value, then that point becomes an improved point. If there is no improvement in the function values, then the step length is reduced by half and the search is repeated in all directions. The algorithm terminates when the step size falls below a certain tolerance.

The Compass optimizer initially makes rapid progress towards the solution. While this method might quickly approach the minimum value of an objective function, it may be slow to detect this fact. It may also converge very slowly if the level sets of the objective function are extremely elongated.

### 11.3.2. The NEWUOA Optimizer

The NEW Unconstrained Optimization Algorithm (NEWUOA) optimizer [77 (p. 2561)] attempts to find the least value of a function \( F^*(x) \), where \( x \) is a parameter vector of \( n \) dimensions. At the start of every iterative step, a quadratic model approximation \( \tilde{Q} - F \) is constructed and the minimization is performed on a trust region (that is, a region around the parameter that is limited by an initial parameter variation). The perturbation to the parameter value needed to obtain the lowest value of \( \tilde{Q} \) is evaluated during the iteration, and correspondingly, the new least value of \( F^*(x) \) is obtained. The iterative process continues until the trust region is reduced to the optimizer convergence criterion, and the optimizer exits with the least value of the objective function. This optimization algorithm can be applied to any setup case of the mesh morpher/optimizer.

The NEWUOA optimizer provides the least value of the objective function in a manner that is highly accurate and robust. The main advantage of this optimizer is that it is very fast; hence, this optimizer is recommended for problems that have a large number of parameters.

### 11.3.3. The Simplex Optimizer

The Simplex optimizer is also referred to as the Downhill Simplex optimizer [58 (p. 2560)], [40 (p. 2559)] and the Nelder-Mead method [63 (p. 2560)]. It is based on the idea of geometric simplexes; for example, a 2D simplex is a triangle, and a 3D simplex is a tetrahedron.

For optimization purposes, ANSYS Fluent requires that simplexes are regular polyhedra (that is, not degenerate polyhedra with collapsed sides). Each vertex of the geometric simplex represents one function evaluation (which in this case is one CFD run), and the number of vertices corresponds to the number of parameters. For the free form deformation method that is used by ANSYS Fluent to parameterize changes in shapes, the number of active control points will determine the number of vertices of the geometric simplex.

Minimization of the objective function is performed based on a set of the rules about the "quality" of each vertex. The vertex quality is the value of the function evaluated for each position of the control point. A set of geometric operations such as reflection, expansion, contraction, and shrinking are performed in order to find the region in which to look for the minimum of the function. Because optimization here is formulated as a minimization problem, the simplex optimizer algorithm seeks the "worst" vertex, that is, the vertex that has the largest value when the corresponding parameter is evaluated. By performing the reflection around the center of the gravity, the new value of the function is obtained after performing the CFD run. Similarly, the operations of expansion, contraction, and shrinking are used to obtain the minimum of the function.

The Simplex optimizer is known to work well, but it suffers from the large number of function evaluations. It also requires smooth objective functions for convergence.
11.3.4. The Torczon Optimizer

The Torczon optimizer [111 (p. 2563)] is a slightly modified version of the simplex optimizer described previously. Given an initial vertex, this optimizer tries to find a better vertex that has a function value that is strictly less than the function value at the previous best vertex. There are three possible trial steps: the rotation step, the expansion step, and the contraction step. The algorithm always computes the rotation step and then tests to see if a new best vertex has been identified. If it has, then the expansion step is computed. Otherwise, the algorithm computes and automatically accepts the contraction step.

11.3.5. The Powell Optimizer

For the Powell optimizer, the method used is based on the number of dimensions of the problem. For optimization problems of single dimension (that is, problems with a single parameter), the golden section search algorithm [78 (p. 2561)] is used to find the optimal value for the objective function. In this algorithm, the optimal value is found by reducing the size of the bracketing triplet, until the size of the bracket (that is, the distance between the outer points of the triplet) reaches a certain tolerance level. In all the cases, the middle point of the new triplet is determined to be the best value obtained so far.

For multidimensional problems (that is, problems with multiple parameters), the minimum value and the largest decrease is found using the golden search algorithm for each dimension, in order to find the conjugate directions. A conjugate direction is a direction that when searched will not alter the minimum value attained by the previous movement in another direction; in other words, a direction in which the gradient is perpendicular to the first direction. After finding the N linearly independent, mutually conjugate directions, one pass will find the exact minimum value. For functions that are not quadratic, repeated cycles of N line minimizations will converge to minimum.

11.3.6. The Rosenbrock Optimizer

In the Rosenbrock optimizer [83 (p. 2561)], after the initial direction is found, multiple steps are taken in that direction until the least value is attained. The process starts with an arbitrary length $e$. If this initial step succeeds (that is, the new value of the function is less than or equal to the old value), the length $e$ is multiplied by $\alpha$, where $\alpha$ is more than 1. If the steps fails, the length $e$ is multiplied by $\beta$, where $\beta$ is between -1 and 0. The direction or the parameter that must be modified is determined by advancing all the parameters by the step length $e$ and then selecting the best among those that yield a function value that is less than the previous value. After that point is accepted as the best point, the process is repeated. These steps continue to repeat until $e$ becomes so small so that any further change in the value of $e$ does not significantly reduce the value of the function.

11.4. Setting Up the Mesh Morpher/Optimizer

The procedure for setting up and using the mesh morpher/optimizer for shape optimization is as follows:

1. Read the case into ANSYS Fluent.
   
   File → Read → Case...

2. If you want to use one of the built-in optimizers rather than specifying the deformation manually or using Design Exploration in ANSYS Workbench to explore multiple deformation scenarios, you will need to provide an objective function in one of three ways: either as a user-defined function (UDF), a Scheme source file, or a customized function that is based on output parameters (that is, values from flux, force, surface integral, or volume integral reports). The goal of the optimizer is to deform the mesh in such a
way that this objective function is minimized. ANSYS Fluent will run the solution for a given design stage until convergence is reached, and then check to see if the objective function is satisfied. If the objective function is not satisfied, ANSYS Fluent will proceed to the next design, and so on, until convergence is achieved from the point of view of the optimizer. You can specify the optimizer convergence criteria in step 8.d.iii.

Note that if you plan to use the `newuoa` optimizer, you must define the objective function as a UDF.

a. If you want to provide the objective function as a user-defined function (UDF), perform the steps that follow. For more information about UDFs, see the separate UDF Manual.

i. Write a UDF using the `DEFINE_ON_DEMAND` macro to define the objective function. The function name must be `objective_function`. At the end of the objective function, the `rpvar Morph::objective_function` must be set to the `(current − target)` value. It is this value that the optimizer will attempt to minimize.

ii. Compile the UDF using the Compiled UDFs dialog box. Make sure `libudf` appears as the Library Name.

   Define → User-Defined → Functions → Compiled...

b. If you want to provide the objective function as a Scheme source file, perform the following steps:

i. Write a Scheme source file to define the objective function. The procedure name must be `objective-function`. At the end of the objective function, the `rpvar morph::objective-function` must be set to the `(current − target)` value. It is this value that the optimizer will attempt to minimize.

ii. Load the Scheme source file (see Reading Scheme Source Files (p. 57) for details).

3. Open the Mesh Morpher/Optimizer dialog box by clicking the Define/Mesh Morpher/Optimizer... menu item.

   Define → Mesh Morpher/Optimizer...

The first time you select the Define/Mesh Morpher/Optimizer... menu item in a session, a question dialog box will ask you whether you want to enable the mesh morpher/optimizer. Click Yes to load the libraries and open the Mesh Morpher/Optimizer dialog box (Figure 11.1: The Regions Tab of the Mesh Morpher/Optimizer Dialog Box (p. 678)).
4. Define the region(s) of the domain where the mesh will be deformed in order to optimize the shape, by performing the following steps in the **Mesh Morpher/Optimizer** dialog box. Each deformation region will be defined as a “box”; that is, a rectangle for 2D cases and a rectangular hexahedron for 3D cases.

**Important**

It is recommended that you define each deformation region to be bigger than the area of interest, in order to maintain proper continuity between deforming and non-deforming regions.

a. Click the **Regions** tab (**Figure 11.1: The Regions Tab of the Mesh Morpher/Optimizer Dialog Box** (p. 678)).
b. Enter a name for a deformation region in the text-entry box at the top of the Name group box.

c. You have the option of using the boundary zones to create a bounding box for the deformation region; this box can represent the final scope of the region, or it can act as a starting point that is further refined by manually editing the origin, direction vectors, and size of the region (as described in the steps that follow). Perform the following steps in the Update from Zones group box:

i. Select the zones from the Boundary Zones list that best represent the extents of the deformation region you would like to create.

ii. Click the Define button in the Bounding Box group box to update the values in the Origin, Direction-1 Vector, Direction-2 Vector (for 3D cases), and Size of Region group boxes.

iii. You can increase or decrease the size of the bounding box by clicking the Enlarge and Reduce buttons, respectively. Note that you have the option of setting the scaling factors associated with these buttons via the following text commands:

\[
\text{define} \rightarrow \text{mesh-morpher-optimizer} \rightarrow \text{region} \rightarrow \text{scaling-enlarge}
\]

\[
\text{define} \rightarrow \text{mesh-morpher-optimizer} \rightarrow \text{region} \rightarrow \text{scaling-reduce}
\]

d. You have the option of using the line tool (for 2D cases) or the plane tool (for 3D cases) to define the direction vectors of the deformation region; the values defined can represent the final components of the vectors, or they can act as a starting point that is further refined by manually editing the direction vectors (as described in the steps that follow). Set up the line tool or the plane tool (as described in Using the Line Tool (p. 1587) and Using the Plane Tool (p. 1591), respectively), and then click the Update from Line Tool or Update from Plane Tool button to update the values in the Direction-1 Vector and (for 3D cases) Direction-2 Vector group boxes.

e. Define an origin for the deformation region by entering the Cartesian coordinates of a point in the X, Y, and (for 3D) Z number-entry boxes in the Origin group box.

f. Define the first direction vector of the deformation region relative to the Origin coordinates, by entering values in the X, Y, and (for 3D) Z number-entry boxes in the Direction-1 Vector group box.

For 2D cases, ANSYS Fluent will automatically define the second direction vector of the deformation region to be perpendicular to the Direction-1 Vector, and will display the components in the uneditable Direction-2 Vector group box.

g. For 3D cases, define the second direction vector of the deformation region relative to the Origin coordinates, by entering values in the X, Y, and Z number-entry boxes in the Direction-2 Vector group box. If the vector you define is not perpendicular to the Direction-1 Vector, ANSYS Fluent will automatically redefine the second vector to be the projection of the Direction-2 Vector you entered onto a plane that is perpendicular to the Direction-1 Vector. Based on this definition, the Direction-2 Vector you define cannot be colinear with the Direction-1 Vector.

The third direction vector of the deformation region will be automatically defined as the cross product of the first and second direction vectors.

h. Define the overall dimensions of the deformation region by entering length values for Direction-1, Direction-2, and (for 3D cases) Direction-3 in the Size of Region group box.

i. Define the number of control points you want along each direction vector of the deformation region by entering values for Direction-1, Direction-2, and (for 3D cases) Direction-3 in the Control Points group box.
group box. The total number of control points for the region will be the product of the numbers you enter. Increasing the number of control points allows you greater control of the deformation, but also increases the computational expense.

**Important**

When you define multiple deformation regions, you must ensure that all the deformation regions have the same total number of control points.

j. Save the settings you have created for the deformation region by clicking the **Create** button. The name of the deformation region will be added (and selected) in the selection list at the bottom of the **Name** group box. A new default name will be automatically entered in the text-entry box at the top of the **Name** group box, in preparation for any deformation regions you want to create in the future.

Note that the control points and bounding box of the deformation region selected in the **Name** selection list will be automatically displayed in the graphics window (see **Figure 11.2: Displaying the Control Points of a Deformation Region** (p. 680)). If you do not want the control points and bounding box displayed in the graphics window, you can deselect the item by clicking the button located above the right side of the **Name** selection list.

**Figure 11.2: Displaying the Control Points of a Deformation Region**
k. If you need to modify the deformation region at any point, select it in the Name selection list, revise the appropriate settings, and click the Modify button. The updated control points and bounding box will be displayed in the graphics window.

**Important**

When modifying an existing deformation region, be sure to click **Modify** rather than **Create**. If you click **Create**, you will not modify the deformation region, but will instead create a new one with the modified settings.

l. If you need to delete the deformation region at any point, select it in the Name selection list and click the **Delete** button.

m. Create any additional deformation regions as necessary by repeating steps 4.b.–l.

**Important**

Overlapping deformation regions are not supported.

5. You have the option of defining constraints on the boundary zones, in order to limit the freedom of particular zones that fall within the deformation region(s) during the morphing of the mesh. The following options are available:

- **unconstrained**

  This option specifies that the boundary zone is completely free to be deformed according to the assigned parameters. By default, all wall zones are unconstrained.

- **fixed**

  This option specifies that the boundary zone is fixed and will not be deformed. None of the zones are fixed by default.

  **Important**

  If you specify one or more fixed boundary zones in a deformation region, you must ensure that there is at least one unconstrained boundary zone in the region as well.

- **passive**

  This option specifies that the nodes of the boundary zone are partially constrained to varying degrees, based on their proximity to adjacent boundary zones that are fixed. The nodes in a passive boundary zone behave in a similar manner to the interior mesh nodes, in order to ensure that there is a smooth transition between fixed and unconstrained boundary zones. By default, all boundary zones that are not walls (for example, inlets, outlets, symmetry, and periodic boundaries) are passive.

To define the constraints on the boundary zones, perform the following steps.
a. Click the **Constraints** tab (Figure 11.3: The Constraints Tab of the Mesh Morpher/Optimizer Dialog Box (p. 682)).

**Figure 11.3: The Constraints Tab of the Mesh Morpher/Optimizer Dialog Box**

b. To revise the default constraint on a boundary zone, select the zone name from the **Zones** selection list in the **Constraints** group box, and then select either **Unconstrained**, **Passive**, or **Fixed** from the **Options** list.

c. Click **Display** if you want view the boundary zone selected from the **Zones** selection list, in order to verify the zone for which you are defining constraints.

d. Click **Summary** if you would like to print a list in the console that summarizes the constraint definitions for all of the boundary zones.
6. Assign the deformation parameters to the control points.
   
a. Click the **Regions** tab and select a region from the **Name** selection list, so that it is displayed in the graphics window.

b. Click the **Deformation** tab (Figure 11.4: The Deformation Tab of the Mesh Morpher/Optimizer Dialog Box (p. 683)).

**Figure 11.4: The Deformation Tab of the Mesh Morpher/Optimizer Dialog Box**

![Image of the deformation tab](image)

   c. Enter the **Number of Parameters** that will be used to define the deformation. This number may be as low as the maximum number of parameters you will define on a single control point, or as high as the total number of parameters you will set on all of the control points combined.
d. If you want to manually specify the deformation or use Design Exploration in ANSYS Workbench to explore multiple deformation scenarios (rather than using the built-in optimizers), define the parameter fields in the Parameter Values group box. Note that these fields are only available when none or workbench is selected from the Optimizer drop-down list in the Optimizer tab. The value of the parameter defines a magnitude that will then be multiplied with the directional components you specify in the Scaling Factors group box to produce an overall displacement for a given control point. You have the following options:

- If you plan to manually specify the deformation, enter a numeric value for each field in the Parameter Values group box.

- If you plan to use Design Exploration in ANSYS Workbench, click the icon next to each parameter field and use the Select Input Parameter dialog box that opens to create or assign an input parameter with an initial value; see Select Input Parameter Dialog Box (p. 2097) for details.

When you have finished defining the parameter fields, click the Apply button in the Parameter Values group box to save the definitions.

e. You have the option of limiting how much each parameter is allowed to deform by defining strict minimum and maximum values. This can be useful when you need to keep the parameters within a certain tolerance of the initial design, or when you know in advance that certain designs are impractical. While this option is typically used with the built-in optimizers, it is available for manual deformation, so that you can visualize the effects of the bounds and set them interactively. Note that this option is not available when workbench is selected from the Optimizer drop-down list in the Optimizer tab.

Click the Set Bounds... button in the Parameter Values group box to open the Parameter Bounds dialog box (Figure 11.5: The Parameter Bounds Dialog Box (p. 684)).

**Figure 11.5: The Parameter Bounds Dialog Box**

![Parameter Bounds Dialog Box](Figure URL)

Select the parameters you want to limit from the Parameters selection list, disable the Unbounded option in the Range group box, and then enter appropriate values for Min and Max.

At any point you can click the Apply button to save your bounds, and you can click the Summary button to display a summary of the saved bounds in the console. When all of the parameter bounds are defined to your satisfaction, click the OK button to close the Parameter Bounds dialog box.
f. Click the **Scaling Factor Settings...** button to open the **Scaling Factor Settings** dialog box (Figure 11.6: The Scaling Factor Settings Dialog Box (p. 685)).

**Figure 11.6: The Scaling Factor Settings Dialog Box**

![Scaling Factor Settings Dialog Box](image)

---

g. (optional) If you have previously generated an ASCII text file that contains scaling factor settings, you can read it by clicking **Read from File...** at the bottom of the **Scaling Factor Settings** dialog box and using the dialog box that opens; otherwise, you should proceed to steps 6.h–6.p and define the settings using the other controls in the **Scaling Factor Settings** dialog box.

Using a text file can be helpful when you have a large number of scaling factor settings. It is not necessary to create the text file from scratch, as you can create a simplified text file with sample values using the **Write to File...** button (as described in step 6.p.), and then add the bulk of the scaling factor settings using a spreadsheet program. See Mesh Morpher/Optimizer File Format (p. 2550) for details about the format of the text file.

---

**Important**

Immediately after you read a text file, the **Scaling Factor Settings** dialog box will not display the applied settings. To begin viewing the applied settings, make a selection in either the **Region**, **Control Points**, or **Parameters** field.
You can then edit the scaling factor settings as necessary (in a manner similar to steps 6.h.–p.) and/or proceed to step 6.q.

h. Select the same region you selected in step 6.a. (that is, the displayed region) from the **Region** drop-down list in the **Scaling Factor Settings** dialog box.

i. Specify the control points in the current **Region** to which you want to assign the same combinations of parameters and scaling factors. You can specify these control points using one or more of the following methods:

- Select the ID numbers from the **Control Points** selection list. The selected control points will be highlighted in the graphics window.

- Click the **Multi-Probe** button in the **Selection Tools** group box and then select the control points in the graphics window with the **mouse-probe** button of the mouse (see *Controlling the Mouse Button Functions* (p. 1654) for details). To deselect, select a highlighted control point with the **mouse-probe** button. As you select the control points, they will also be selected in the **Control Points** selection list.

- Use the **Indexed Grouping** group box to select the control points based on their assigned indices. Each control point has \( I, J, \) and (for 3D cases) \( K \) index numbers, each of which denote its place in the sequence (starting at the origin of the region) of control points along the direction-1, direction-2, and direction-3 vectors, respectively (as defined in the **Regions** tab of the **Mesh Morpher/Optimizer** dialog box). You can make selections from the index drop-down lists, and then click the **Select** button. In a similar way you can deselect control points using the **Deselect** button. As you select the control points, they will also be selected in the **Control Points** selection list and highlighted in the graphics window.

For example, consider the case of a 3D region: if you select 2 from the \( k \) drop-down list, the control points in the second plane perpendicular to the direction-3 vector (that is, the direction-1–direction-2 plane) will be selected. If you select 1 from both the \( I \) and \( J \) drop-down lists, the line of control points at the intersection of the first planes perpendicular to the direction-1 and direction-2 vectors will be selected. Making selections from all three drop-down lists will select a single control point.

j. Make selections from the **Parameters** selection list, in order to specify those you want to assign (along with a particular set of scaling factors) to the selected **Control Points**. Note that the values associated with these parameters (as displayed in the **Parameter Values** group box in the **Deformation** tab of the **Mesh Morpher/Optimizer** dialog box) are irrelevant if you plan to use the built-in optimizers.

k. Define the scaling factors that will be associated with the selected **Parameters** by entering values for the **X**, **Y**, and (for 3D cases) **Z** directions in the **Scaling Factors** group box. If you use a built-in optimizer, these scaling factors provide the direction of the displacement of the control point and the optimizer determines the overall magnitude of displacement. Alternatively, if you specify the deformation manually or using Design Exploration, the values you enter in the **Scaling Factors** group box are multiplied with the values of the **Parameters** to define the displacement applied to the control points.

l. Click the **Apply** button to save the scaling factor settings.

m. If you want to apply a different combination of parameters and scaling factors for the selected **Control Points**, repeat steps 6.j–6.l for each additional combination.
n. Repeat steps 6.i–6.m for each additional set of control points in the current **Region** to which you want to assign scaling factor settings.

o. Repeat steps 6.a–6.n for each additional region in which you want to apply deformation parameters to control points.

p. If you want to save all of the settings you specified in the **Scaling Factor Settings** dialog box as an ASCII text file, click **Write to File...** and specify a name in the dialog box that opens. You can edit the scaling factor settings in this text file using a spreadsheet program, and then read it in this or a separate case file, as described in step 6.g.

q. Click **OK** to close the **Scaling Factor Settings** dialog box.

r. If **none** is selected from the **Optimizer** drop-down list in the **Optimizer** tab of the **Mesh Morpher/Optimizer** dialog box, you can click the **Deform** button to apply the current settings in the **Parameter Values** group box and display the deformed mesh in the graphics display. The **Deform** button allows you to manually specify the deformation.

s. If **none** is selected from the **Optimizer** drop-down list in the **Optimizer** tab, you can click the **Check** button to print out a mesh check report in the console for the currently displayed mesh. The mesh check report is the same as that produced by the **Check** button in the **General** task page, as described in **Mesh Check Report** (p. 162).

---

**Important**

If you save parameter settings but do not click the **Deform** button, the mesh check report will not account for the mesh that is produced from those settings.

---

t. Click the **Reset** button if you want to revert to the original mesh without the deformations that result from the **Deform** button.

7. If you plan to use the built-in optimizers, you should decide whether you want to disable the general mesh check that is performed by default immediately after the mesh is deformed in every design stage. The mesh check that is performed is the same as that initiated by the **Check** button in the **General** task page (see **Checking the Mesh** (p. 162) for details). If any errors are discovered, the mesh is rejected and the next design stage is attempted.

Disabling the general mesh check allows you to repair the mesh, so that an accurate solution can be calculated for it. Note that you can set up the mesh repair by entering the appropriate text commands (as described in **Repairing Meshes** (p. 164)) in the **Initial Commands** text-entry box in the **Optimizer** tab.

You can disable the general mesh check by using the following text command:

```
define \rightarrow mesh-morpher-optimizer \rightarrow optimizer-parameters \rightarrow disable-mesh-check
```

8. If you want to use the built-in optimizers, define the optimizer settings and initiate the optimization process.

a. Click the **Optimizer** tab (Figure 11.7: The Optimizer Tab of the Mesh Morpher/Optimizer Dialog Box (p. 688)).
b. Select an optimizer from the **Optimizer** drop-down list. The available optimizers are not based on gradients, and include the following: **compass**, **newuoa**, **powell**, **rosenbrock**, **simplex**, and **torczon**. For more information about how these optimizers function, see Optimizers (p. 674).

c. Click the **Objective Function Definition...** button to open the **Objective Function Definition** dialog box (Figure 11.8: The Objective Function Definition Dialog Box (p. 689)).
i. Make a selection in the **Options** group box to specify whether the objective function that will be minimized during the optimization process is a **User-Defined Function**, a **Scheme Procedure**, or a customized function of output parameters as defined by the **Custom Calculator**. Your selection should correspond with the actions you took in step 2.

ii. If you selected **Custom Calculator** in the previous step, define the objective function via the GUI controls in the **Custom Calculator** group box. As you click the buttons in this group box, text and symbols will appear in the **Function to Minimize** text box. You **cannot** edit the contents of this box directly; if you want to delete part or all of the function, use the **DEL** or **Clear** button, respectively.

You can include output parameters in the definition of the function by making a selection from the **Output Parameters** list and clicking **Select**. If you want to add a new output parameter to the selection list or check the definition of an existing one, you can click the **Parameters...** button and use the **Parameters** dialog box (as described in Creating Output Parameters (p. 1743)); be sure to click the **Refresh** button when you return to the **Objective Function Definition** dialog box, so that the **Output Parameters** list is updated. You can also use **Operators** to manipulate the output parameters in the function.

You can click the **Apply** button at any point to save your function. When it is fully defined, click the **OK** button to save your settings and close the **Objective Function Definition** dialog box.

d. Define the settings in the **Optimizer Settings** group box.
i. Enter a value for **Maximum Number of Designs**, to specify the maximum number of design stages the optimizer will undergo to reach the specified objective function. Note that this number is not the number displayed in the console during the optimization process. Each optimizer undergoes a certain number of design modifications (called “runs”) before it converges to a design for a particular design stage. The Run number displayed in the console refers to the actual design modifications (including the inner loop) irrespective of the optimizer, whereas the **Maximum Number of Designs** value is the maximum number of converged designs provided by the optimizer.

ii. Enter the **Maximum Iterations per Design**, to specify the maximum number of iterations ANSYS Fluent performs for each design change.

iii. Enter a number for **Optimizer Convergence Criteria**, to specify the convergence criteria for the optimizer.

iv. If you selected the newuoa optimizer, enter a number for the **Initial Parameter Variation** to specify how much the parameters will be allowed to vary during the initial calculations. This value is not intended to define a strict minimum / maximum for the parameters (as is defined by the bounds specified using the **Parameter Bounds** dialog box), but should only be large enough to allow the optimizer to capture the minima. A better estimation (that is, a smaller value) allows the optimizer to reach convergence faster.

e. By default, the orthogonal quality (as defined in **Mesh Quality** (p. 129)) of the initial and every subsequent mesh is computed, before the related solution calculation is initiated. If the orthogonal quality for any cell is less than a specified value, the mesh is rejected and Fluent proceeds to the next design stage (therefore helping to ensure that your solution accuracy is not compromised by poor quality meshes). These actions are governed by the settings in the **Mesh Quality** group box.

If you do not want the meshes rejected based on their orthogonal quality, you can disable the **Reject Poor Quality Meshes** option; otherwise, specify the minimum orthogonal quality that must be maintained by every cell by entering a value from $0 - 1$ (where $0$ represents the worst quality) for **Minimum Orthogonal Quality**. When determining an appropriate minimum value, you can check the orthogonal quality of the initial mesh (by using the **Report Quality** button in the **General** task page) and then select a value that is sufficiently lower, so as not to reject a majority of the meshes generated during the optimization process.

f. You have the option of saving intermediate case and data files during the optimization run, so that you can restart an interrupted solution in the same or a different Fluent session without increasing the overall number of design iterations needed to reach convergence. To enable the saving of such intermediate files, define the settings in the **Case and Data File Set** group box.

i. Specify the frequency (in number of design iterations) that you want the intermediate case and data files saved by entering a value for **Save Every**. The default value is $0$, which specifies that no intermediate files will be saved. Note that if you selected the newuoa optimizer, the frequency at which files are saved may not exactly correspond to the number you enter, but should be reasonably close.

ii. Specify the maximum number of intermediate files sets you want to retain by entering a value for **Maximum Number Retained**. After the maximum limit of file sets has been saved, ANSYS Fluent begins overwriting the earliest existing intermediate file set. Lower values should be used if you have limited disk space or you are concerned about saving unnecessary files.
iii. Specify a root name for the intermediate files in the File Name text box. When the files are saved, the design iteration will be appended to this root name to indicate the point at which it was saved during the optimization run. An extension will also be automatically added to the root name (\texttt{.cas} or \texttt{.dat}). You can include a folder path in the file name if you want the files saved outside of the working folder.

g. Specify how the solution variables should be treated after the mesh is deformed by making a selection from the Method list in the Initialization group box:

- Select \texttt{Initialize Data After Morphing} to specify that the solution variables should be initialized to the values specified in the Solution Initialization task page after deformation.

- Select \texttt{Continue with Current Data} to specify that the solution variables remain the values obtained in the previous design stage. This selection will reduce the number of iterations needed to reach convergence compared to the \texttt{Initialize Data After Morphing} selection. Note that if the solver diverges during an intermediate design stage, the solution variables will be initialized and the solution will be attempted again.

- Select \texttt{Read Data File After Morphing} to specify that the solution variables are set to the values obtained from the data file specified in the Data File Name text-entry box. This selection will reduce the number of iterations needed to reach convergence compared to \texttt{Initialize Data After Morphing} selection or (in cases where the solution diverges for an intermediate design stage) the \texttt{Continue with Current Data} selection. Note that this selection is not available when \texttt{newuoa} is selected from the Optimizer drop-down list.

h. If you did not select the \texttt{newuoa} optimizer, you have the option of specifying commands that will be executed during the optimization runs of the mesh morpher/optimizer, via the text-entry boxes in the Execute Commands group box. A command can be a text command or the name of a command macro you have defined (or will define), as described in Defining Macros (p. 1503). You can also enter a series of text commands and/or macros, as long as they are separated by a semi-colon (;).

During optimization runs, deformation occurs as part of every design iteration. You decide the specific point during the design iteration that the command is executed:

- If you want a command to be executed after the design has been modified, but before ANSYS Fluent has started to run the calculation for that design stage, enter the command in the Initial Commands text-entry box. There are no restrictions on the commands that can be entered: you can enter commands that read saved data, perform FMG initialization, execute an entirely independent on-demand UDF, or even call a Scheme routine.

- If you want a command to be executed after the solution has run and converged for a design stage, enter the command in the End Commands text-entry box. There are no restrictions on the commands that can be entered. Examples are commands for postprocessing solution variables, monitoring contours and vectors of different variables, taking snapshots of each design change, etc. at every design stage.

\textbf{Important}

If the command to be executed involves saving a file, see Saving Files During the Calculation (p. 1504) for important general information.
As noted in Automatic Numbering of Files (p. 45), the special character, `%i`, can be used to create unique file names by including the iteration number. However, by default, the solution will be initialized after each mesh deformation and the iteration count restarted. Therefore, the resulting file name cannot be used to identify which design stage produced it (that is, the first design stage may converge at 50 iterations, and then the second design stage may converge at 43 iterations). The time that the file was created is a better way to identify where in the series of design stages the file was generated. In addition, some files may be overwritten if two design stages converge in the same number of iterations. Alternatively, if you have selected **Continue with Current Data** under **Initialization** when setting up the optimizer, then the iteration count will not reset and no duplicate filenames will occur.

i. If you did not select the **newuoa** optimizer, you can plot and/or record the optimization history (that is, how the value of the objective function varies with each design stage). Click the **Monitor...** button to open the **Optimization History Monitor** dialog box (Figure 11.9: The Optimization History Monitor Dialog Box (p. 692)) and perform the steps that follow.

**Figure 11.9: The Optimization History Monitor Dialog Box**

![Optimization History Monitor Dialog Box](image)

i. Enable the **Plot** option if you want to display a plot of the optimization history in the graphics window indicated in the **Window** number-entry box. Note that if you want to observe the mesh deformations during the optimization process, you must make sure that **Window** is not set to the ID of the graphics window that is displaying the mesh.

ii. Enable the **Write** option if you want to save the optimization history data in a file, and specify the **File Name**.

Note that you can display a plot of the optimization history data generated during the last calculation, even if the **Plot** or the **Write** options were not enabled during the calculation, as long as you have not discarded the data using the **Clear** button. Simply click the **Plot** button and the plot will be displayed in the active graphics window.

j. Click the **Apply** button to save your optimizer settings.

k. Click the **Summary** button to display a summary of the mesh morpher/optimizer settings in the console.
1. Click the **Optimize** button to initiate the optimization process. Information about each run (that is, each design modification) that is generated as part of the production of a design stage will be displayed in the console, and the deformed mesh for each run will be updated in the graphics window.

If you set up the saving of intermediate case and data files in step 8f and your solution is interrupted during the optimization run, you can restart the calculation using the latest intermediate files. Note that you should not revise the deformation regions or constraint settings for the re-started mesh.

9. If you want to use Design Exploration in ANSYS Workbench to explore multiple deformation scenarios, define the optimizer settings.

   a. Click the **Optimizer** tab (Figure 11.7: The Optimizer Tab of the Mesh Morpher/Optimizer Dialog Box (p. 688)).

   b. Select `workbench` from the Optimizer drop-down list. Note that `workbench` is only available if you have launched your ANSYS Fluent session from ANSYS Workbench.

   c. If necessary, revise the default settings in the **Mesh Quality** group box, as described in step 8e. Note that the design point associated with a poor quality mesh will not be updated in Workbench.

10. Click **OK** to close the **Mesh Morpher/Optimization** dialog box.

11. If you want to use Design Exploration in ANSYS Workbench to explore multiple deformation scenarios, save your case file and close your ANSYS Fluent session. You can then proceed to ANSYS Workbench and define the design points that will provide the multiple values for the input parameters you created / assigned in step 6d. For more information about using design points to explore ANSYS Fluent results, see *Working With Input and Output Parameters in Workbench* in the ANSYS Fluent in Workbench User’s Guide.

12. If you manually deformed the mesh or used the built-in optimizers, run your case file with the deformed mesh.

13. If you want to rerun a case file in which the mesh has been deformed by the **Optimize** button in the **Optimizer** tab, you should not revise the deformation regions or constraint settings for the deformed mesh.
Chapter 12: Modeling Turbulence

This chapter provides details about how to use the turbulence models available in ANSYS Fluent.

Information about turbulence modeling theory is presented in Turbulence in the Theory Guide. Information about using the turbulence models can be found in the following sections:

12.1. Introduction
12.2. Choosing a Turbulence Model
12.3. Steps in Using a Turbulence Model
12.4. Setting Up the Spalart-Allmaras Model
12.5. Setting Up the k-ε Model
12.6. Setting Up the k-ω Model
12.7. Setting Up the Transition k-kl-ω Model
12.8. Setting Up the Transition SST Model
12.9. Setting Up the Intermittency Transition Model
12.10. Setting Up the Reynolds Stress Model
12.12. Setting Up the Detached Eddy Simulation Model
12.13. Setting Up the Large Eddy Simulation Model
12.14. Model Constants
12.15. Setting Up the Embedded Large Eddy Simulation (ELES) Model
12.16. Setup Options for All Turbulence Modeling
12.17. Defining Turbulence Boundary Conditions
12.18. Providing an Initial Guess for k and ε (or k and ω)
12.20. Postprocessing for Turbulent Flows

12.1. Introduction

Turbulence is the three-dimensional unsteady random motion observed in fluids at moderate to high Reynolds numbers. As technical flows are typically based on fluids of low viscosity, almost all technical flows are turbulent. Many quantities of technical interest depend on turbulence, such as:

- Mixing of momentum, energy and species
- Heat transfer
- Pressure losses and efficiency
- Forces on aerodynamic bodies
- etc.

While turbulence is, in principle, described by the Navier-Stokes equations, it is not feasible in most situations to resolve the wide range of scales in time and space by Direct Numerical Simulation (DNS) as the CPU requirements would by far exceed the available computing power for any foreseeable future. For this reason, averaging procedures have to be applied to the Navier-Stokes equations to filter out all, or at least, parts of the turbulent spectrum. The most widely applied averaging procedure is Reynolds-
averaging (which, for all practical purposes is time-averaging) of the equations, resulting in the Reynolds-Averaged Navier-Stokes (RANS) equations. By this process, all turbulent structures are eliminated from the flow and a smooth variation of the averaged velocity and pressure fields can be obtained. However, the averaging process introduces additional unknown terms into the transport equations (Reynolds Stresses and Fluxes) that need to be provided by suitable turbulence models (turbulence closures). The quality of the simulation can depend crucially on the selected turbulence model and it is important to make the proper model choice as well as to provide a suitable numerical grid for the selected model. An alternative to RANS are Scale-Resolving Simulation (SRS) models. With SRS methods, at least a portion of the turbulent spectrum is resolved in at least a part of the flow domain. The most well-known such method is Large Eddy Simulation (LES), but many new hybrids (models between RANS and LES) are appearing. As all SRS methods require time-resolved simulations with relatively small time steps, it is important to understand that these methods are substantially more computationally expensive than RANS simulations.

ANSYS Fluent provides the following choices of turbulence models:

- Spalart-Allmaras model
- $k$-$\varepsilon$ models
  - Standard $k$-$\varepsilon$ model
  - Renormalization-group (RNG) $k$-$\varepsilon$ model
  - Realizable $k$-$\varepsilon$ model
- $k$-$\omega$ models
  - Standard $k$-$\omega$ model
  - Shear-stress transport (SST) $k$-$\omega$ model
- $\nu^2$-$f$ model (add-on)
- Transition $k$-$k\omega$ model
- Transition SST model
- Reynolds stress models (RSM)
  - Linear pressure-strain RSM model
  - Quadratic pressure-strain RSM model
  - Stress-omega RSM model
- Scale-Adaptive Simulation (SAS) model, which can be used in combination with one of the following $\omega$-based URANS models:
  - SST $k$-$\omega$ model
  - Standard $k$-$\omega$ model
  - Transition SST model
12.2. Choosing a Turbulence Model

It is an unfortunate fact that no single turbulence model is universally accepted as being superior for all classes of problems. The choice of turbulence model will depend on considerations such as the physics of the flow, the established practice for a specific class of problem, the level of accuracy required, the available computational resources, and the amount of time available for the simulation. To make the most appropriate choice of model for your application, you need to understand the capabilities and limitations of the various options.

The purpose of this section is to give an overview of issues related to the turbulence models provided in ANSYS Fluent. The computational effort and cost in terms of CPU time and memory of the individual models is discussed. While it is impossible to state categorically which model is best for a specific application, general guidelines are presented to help you choose the appropriate turbulence model for the flow you want to model.

For additional information, see the following sections:
12.2.1. Reynolds Averaged Navier-Stokes (RANS) Turbulence Models
12.2.2. Scale-Resolving Simulation (SRS) Models
12.2.3. Grid Resolution SRS Models
12.2.4. Numerics Settings for SRS Models
12.2.5. Model Hierarchy

12.2.1. Reynolds Averaged Navier-Stokes (RANS) Turbulence Models

RANS models (Reynolds (Ensemble) Averaging in the Theory Guide) offer the most economic approach for computing complex turbulent industrial flows. Typical examples of such models are the k-ε or the k-ω models in their different forms. These models simplify the problem to the solution of two additional transport equations and introduce an Eddy-Viscosity (turbulent viscosity) to compute the Reynolds...
Stresses. More complex RANS models are available that solve an individual equation for each of the six independent Reynolds Stresses directly (Reynolds Stress Models – RSM) plus a scale equation ($\varepsilon$-equation or $\omega$-equation). RANS models are suitable for many engineering applications and typically provide the level of accuracy required. Since none of the models is universal, you have to decide which model is the most suitable for a given application.

### 12.2.1.1. Spalart-Allmaras One-Equation Model

The Spalart-Allmaras model is a relatively simple one-equation model that solves a modeled transport equation for the kinematic eddy (turbulent) viscosity. The Spalart-Allmaras model was designed specifically for aeronautics and aerospace applications involving wall-bounded flows and has been shown to give good results for boundary layers subjected to adverse pressure gradients. It is also gaining popularity in turbomachinery applications. Do not use the model as a general purpose model, as it is not well calibrated for free shear flows (large errors for example, jet flows).

The Spalart-Allmaras model has been extended within ANSYS Fluent with a $y^+$-insensitive wall treatment (Enhanced Wall Treatment (EWT)). The EWT automatically blends all solution variables from their viscous sublayer formulation to the corresponding logarithmic layer values depending on $y^+$. The blending is calibrated to also cover intermediate $y^+$ values in the buffer layer ($1 < y^+ < 30$).

### 12.2.1.2. $k-\varepsilon$ Models

Two-equation models are historically the most widely used turbulence models in industrial CFD. They solve two transport equations and model the Reynolds Stresses using the Eddy Viscosity approach. The standard $k-\varepsilon$ model in ANSYS Fluent falls within this class of models and has become the workhorse of practical engineering flow calculations in the time since it was proposed by Launder and Spalding [48] (p. 2559). Robustness, economy, and reasonable accuracy for a wide range of turbulent flows explain its popularity in industrial flow and heat transfer simulations.

The draw-back of some $k-\varepsilon$ models is their insensitivity to adverse pressure gradients and boundary layer separation. They typically predict a delayed and reduced separation relative to observations. This can result in overly optimistic design evaluations for flows that separate from smooth surfaces (aerodynamic bodies, diffusers, etc.). The $k-\varepsilon$ model is therefore not widely used in external aerodynamics.

In ANSYS Fluent, the use of the Realizable $k-\varepsilon$ model is recommended relative to other variants of the $k-\varepsilon$ family. It is recommended to use the $k-\varepsilon$ model in combination with the Enhanced Wall Treatment (EWT). Refer to Enhanced Wall Treatment $\varepsilon$-Equation (EWT-$\varepsilon$) in the Theory Guide for details. For cases where the flow separates under adverse pressure gradients from smooth surfaces (airfoils, etc.), $k-\varepsilon$ models are generally not recommended.

### 12.2.1.3. $k-\omega$ Models

The $\omega$-equation offers several advantages relative to the $\varepsilon$-equation. The most prominent one is that the equation can be integrated without additional terms through the viscous sublayer. This makes the formulation of robust $y^+$-insensitive Enhanced Wall Treatment (EWT) relatively straightforward. Refer to Enhanced Wall Treatment $\omega$-Equation (EWT-$\omega$) in the Theory Guide for details. Furthermore, $k-\omega$ models are typically better in predicting adverse pressure gradient boundary layer flows and separation. The downside of the standard $\omega$-equation is a relatively strong sensitivity of the solution depending on the freestream values of $k$- and $\omega$- outside the shear layer. The use of the standard $k-\omega$ model is, for this reason, not generally recommended in ANSYS Fluent.
The SST k-ω model has been designed to avoid the freestream sensitivity of the standard k-ω model, by combining elements of the ω-equation and the ε-equation. In addition, the SST model has been calibrated to accurately compute flow separation from smooth surfaces. Within the k-ω model family, it is therefore recommended to use the SST model. The SST model is one of the most widely used models for aerodynamic flows. It is typically somewhat more accurate in predicting the details of the wall boundary layer characteristics than the Spalart-Allmaras model. The SST model (as all ω-equation based models) uses the enhanced wall treatment as default.

For the k-ω models, so-called low Reynolds number terms (low Re) have been proposed by Wilcox. These are available in ANSYS Fluent as an option. It is important to point out that these terms are not required for integrating the equations through the viscous sublayer. Their main influence lies in mimicking laminar-turbulent transition processes. However, this functionality is not widely calibrated and for wall-boundary layer transition, the combination of the SST model with the Transition SST model (Transition SST Model in the Theory Guide), Intermittency Transition model (Intermittency Transition Model in the Theory Guide), or the Transition k-kl model (k-kl Transition Model in the Theory Guide) is more reliable. The use of the low-Re terms is therefore not encouraged.

12.2.1.4. RSM Models

Reynolds Stress models (RSM) include several effects that are not easily handled by Eddy-Viscosity models. The most important effect is the stabilization of turbulence due to strong rotation and streamline curvature (as observed for example, in cyclone flows). RSM on the other hand often demand a significant increase in computing time partly due to the additional equations but mostly due to reduced convergence. This additional effort is not always justified by increased accuracy. Their usage is therefore not generally recommended and should be restricted to flows for which their superiority has been established, especially flow with strong swirl and rotation. If wall boundary layers are important, the combination of RSM and the ω-equation is more accurate than the combination with the ε-equation.

12.2.1.5. Laminar-Turbulent Transition Models

Three models for transition prediction are available in ANSYS Fluent:

- the Transition SST model

- the Intermittency Transition model (available for SST, Scale-Adaptive Simulation with SST, and Detached Eddy Simulation with SST)

- the Transition k-kl model

For many test cases, the three models produce similar results. Due to their combination with the SST model, the Transition SST model and the Intermittency Transition model are recommended over the Transition k-kl model. Among the three models, only the Intermittency Transition model is capable of accounting for crossflow instability.

It is important to note that only these three models can simulate the laminar-turbulent transition of wall boundary layers.

Proper mesh refinement and specification of inlet turbulence levels is crucial for accurate transition prediction. In general, there is some additional effort required during the mesh generation phase because a low-Re mesh with sufficient streamwise resolution is needed to accurately resolve the transition region. Furthermore, in regions where laminar separation occurs, additional mesh refinement is necessary in order to properly capture the rapid transition due to the separation bubble. Finally, the decay of turbulence from the inlet to the leading edge of the device should always be estimated before running a
solution as this can have a large effect on the predicted transition location. Physically correct values for the turbulence intensity \( (T_u) \) should be achieved near the location of transition.

### 12.2.1.6. Curvature Correction for the Spalart-Allmaras and Two-Equation Models

One weakness of the eddy-viscosity models is that these models are insensitive to streamline curvature and system rotations, which play an important role in many turbulent flow applications. To sensitize the standard eddy-viscosity models to these curvature effects, you can use a modified turbulence production term. For more information, see Curvature Correction for the Spalart-Allmaras and Two-Equation Models in the Fluent Theory Guide.

### 12.2.1.7. Production Limiters for Two-Equation Models

A disadvantage of standard two-equation turbulence models is the excessive generation of the turbulence energy, \( G_k \), in the vicinity of stagnation points. In order to avoid the buildup of turbulent kinetic energy in the stagnation regions, the production term in the turbulence equations can be limited by one of the two formulations described in Production Limiters for Two-Equation Models in the Fluent Theory Guide.

### 12.2.1.8. Model Enhancements

There are many model enhancements available for turbulence models. While such enhancements can improve simulations in some cases, they can also have detrimental effects. The general recommendation is therefore to use them with caution.

As noted above, the use of low-Re terms in combination with the \( \omega \)-equation is not generally recommended.

Another model enhancement that should be used with care is the compressibility correction of Sarkar ([85] (p. 2561)). It can improve the prediction of free shear layers at high Mach numbers, but has also shown a pronounced negative impact on wall boundary layers. It is therefore not generally recommended. Compressibility correction is available in the Viscous Model Dialog Box (p. 1903) when the compressible form of the ideal gas law or the real-gas model is activated. The compressibility correction option is disabled by default (though this was not the case in version 14.5 and earlier) and it is recommended that you keep this option disabled for cases not involving free shear flows.

Buoyancy has a pronounced effect on turbulence (Effects of Buoyancy on Turbulence in the Theory Guide). The use of the source term in the \( k \)-equation is therefore recommended for buoyancy affected flows. The source term in the \( \varepsilon \)-equation and \( \omega \)-equation is much less established and the term should be activated with care.

### 12.2.1.9. Wall Treatment for RANS Models

It is recommended that you use the Enhanced Wall Treatment for all models for which it is available (Spalart-Allmaras, \( \varepsilon \)-equation and \( \omega \)-equation). It provides the most consistent wall shear stress and wall heat transfer predictions with the least sensitivity to \( y^+ \) values. (see an Overview of the Spalart-Allmaras model, Enhanced Wall Treatment \( \varepsilon \)-Equation (EWT-\( \varepsilon \)), and Enhanced Wall Treatment \( \omega \)-Equation (EWT-\( \omega \)) in the Theory Guide for more information)

When Wall Functions are used, it is necessary to avoid grids with fine near wall spacing. It is recommended that you use \( y^+ > 30 \) in the entire domain. The application of Wall Functions is, however, not generally recommended as they do not allow a systematic refinement of the near wall grid. Wall Functions
are especially damaging for flows at low to medium Reynolds numbers (Re\(\sim 10^4-10^6\)), as the assumption of an extended logarithmic layer is not valid in these cases. In case that Wall Functions are desired, the option of Scalable Wall Functions (Scalable Wall Functions in the Theory Guide) avoids the grid restrictions and can be run on fine meshes.

### 12.2.1.10. Grid Resolution for RANS Models

Grid generation has a strong impact on model accuracy. There are many considerations that have to be followed when generating high quality CFD grids. From a turbulence modelling standpoint, the most important one is that the relevant shear layers should be covered by at least \(~10\) cells normal to the layer. Below this resolution, the model will not be able to provide its calibrated performance. Especially for free shear flows, whose location is not known during grid generation, this is a requirement that is hard to achieve. Nevertheless, you should be aware that for lower resolution, the model performance can degrade.

For wall bounded flows, a structured mesh in wall-normal direction is highly recommended. The structured portion of the mesh should cover the entire boundary layer and extend beyond the boundary layer thickness to avoid restricting the growth of the boundary layer. Advanced turbulence models for wall boundary layers like the Spalart-Allmaras model and the SST model will only provide improved results to other models if a minimum of \(10\) or more structured (hex or prism) cells are located inside the boundary layer. In addition, one should ensure that the prism layer covers the wall boundary layer entirely. Note that these are not specific requirements of these models, but are general requirements for wall boundary layer simulations.

Both, \(\varepsilon\)-based and \(\omega\)-based models offer Enhanced Wall Treatment options (see Enhanced Wall Treatment \(\varepsilon\)-Equation (EWT-\(\varepsilon\)) and Enhanced Wall Treatment \(\omega\)-Equation (EWT-\(\omega\)) in the Theory Guide for more information), which make the models relatively insensitive to the \(y^+\)-value of the wall cell. Generally speaking, it is more important to ensure that the boundary layer is covered with sufficient cells, then to achieve a certain \(y^+\) criterion. However, for simulations with high accuracy demands on the wall boundary layer (especially for heat transfer predictions) near wall meshes with \(y^+\sim 1\) are recommended. When wall functions are used, it is essential to avoid meshes with \(y^+\) values lower than \(~30\) as the wall shear stress and the wall heat transfer can and will seriously deteriorate under such conditions. For this reason, the usage of Enhanced Wall Treatments (to be selected for \(\varepsilon\)-equation and default for \(\omega\)-equation based models) is recommended.

For transition models (see k-kl-\(\omega\) Transition Model, Transition SST Model, and Intermittency Transition Model in the Theory Guide), more stringent grid resolution requirements apply than for standard RANS models, as transition modelling requires the resolution of the thin laminar boundary layer upstream of the transition location. For this reason, a low-Re mesh (\(y^+\sim 1\)) with sufficient streamwise resolution is needed to accurately resolve the transition region. The expansion ratio of the grid normal to the wall should not exceed \(1.1\). Furthermore, in regions where laminar separation occurs, additional mesh refinement is necessary, in order to properly capture the rapid transition due to the separation bubble. Finally, the decay of turbulence from the inlet to the leading edge of the device should always be estimated before running a solution as this can have a large effect on the predicted transition location.

### 12.2.2. Scale-Resolving Simulation (SRS) Models

The alternative to RANS models are models that resolve at least a portion of the turbulence for at least a portion of the flow domain. Such models are generally termed ‘Scale-Resolving’. 
12.2.2.1. Large Eddy Simulation (LES)

The most widely known SRS modelling concept is Large Eddy Simulation (LES). It is based on the approach of resolving large turbulent structures in space and time down to the grid limit everywhere in the flow. However, while widely used in the academic community, LES had very limited impact on industrial simulations. The reason lies in the excessively high resolution requirements for wall boundary layers. Near the wall, the largest scales in the turbulent spectrum are nevertheless geometrically very small and require a very fine grid and a small time step. In addition, unlike RANS, the grid cannot only be refined in the wall normal direction, but also must resolve turbulence in the wall parallel plane. This can only be achieved for flows at very low Reynolds number and on very small geometric scales (the extent of the LES domain cannot be much larger than 10-100 times the boundary layer thickness parallel to the wall). For this reason the use of LES is only recommended for flows where wall boundary layers are not relevant and need not be resolved or for flows where the boundary layers are laminar due to the low Reynolds number. In such cases, the most balanced LES model is the WALE model (see Wall-Adapting Local Eddy-Viscosity (WALE) Model in the Theory Guide). It offers a good compromise between model complexity and generality. It also allows computing laminar shear (boundary) layers without any model impact.

An extension to LES is Wall-Modeled LES (WMLES). It allows the LES computation of wall bounded flows at higher Reynolds number without the large increase in grid resolution required for conventional LES at high Reynolds numbers. For WMLES, the grid resolution is largely independent of the Reynolds number with respect to the grid cells required per boundary layer volume. An enhanced version of WMLES called WMLES is also available. WMLES does not provide zero eddy-viscosity for flows with constant shear. Therefore, it does not allow the computation of transitional effects, and can produce overly large eddy-viscosities in separating shear layers. The enhanced WMLES formulation overcomes these deficiencies. See Algebraic Wall-Modeled LES Model (WMLES) in the Theory Guide for further details.

12.2.2.2. Hybrid RANS-LES Models

In order to avoid the high resolution requirements of LES, numerous hybrid models have been developed in recent years. These are models that combine certain elements of RANS and LES approaches in a way that allows for the simulation of high Reynolds number flows. With hybrid models, the attached wall boundary layers are typically covered by the RANS part of the model, while large detached regions are handled in ‘LES’ mode, meaning with a partial resolution of the turbulent spectrum in space and time. Hybrid models rely on a strong enough flow instability to generate turbulent structures in the separated zone. This is typically the case for flows behind bluff bodies, where URANS models predict single-mode periodic vortex shedding. Hybrid models allow these vortices to generate smaller eddies down to the available grid limit. Figure 12.1: Illustration of SST-URANS vs. SST-SAS Models (p. 703) shows a typical scenario: While the application of a standard RANS model in unsteady mode results in a single frequency vortex shedding (left), the application of hybrid models allows a break-up of the large structures into smaller scales. This is beneficial for predicting the correct mixing behind the body or to extract spectral information (for example, for acoustic simulations). At the same time, the wall boundary layers are covered by the RANS part of the hybrid model avoiding the excessive resolution requirements of LES.
Figure 12.1: Illustration of SST-URANS vs. SST-SAS Models

Figure 12.1: Illustration of SST-URANS vs. SST-SAS Models (p. 703) shows a circular cylinder in a cross flow at $Re = 3.6 \times 10^6$. The left hand side illustrates the SST-URANS model, while the right-hand side illustrates the SST-SAS model. The iso-surface of $Q = S^2 - \Omega^2$ is colored according to the eddy viscosity ratio $\mu_i/\mu$ (note that the scale in the right-hand side figure is smaller by a factor of 14).

12.2.2.2.1. Scale-Adaptive Simulation (SAS)

The SAS modelling approach (see Scale-Adaptive Simulation (SAS) Model in the Theory Guide) as proposed by Menter et al. ([59] (p. 2560)[60] (p. 2560)) is based on the introduction of the von Karman length scale, $L_{VK}$, into the turbulence equations (in case of the SST model it enters into the $\omega$-equation). $L_{VK}$ is defined as the ratio of the first divided by the second derivative of the velocity vector (times the von Karman constant $\kappa=0.41$):

$$L_{VK} = \kappa \left| \frac{U'}{U''} \right|; \quad U'' = \frac{\partial^2 U_i}{\partial x_k^2} \frac{\partial^2 U_i}{\partial x_j^2} ;$$

$$U' = S \sqrt{2 \cdot S_{ij} S_{ij}} ; \quad S_{ij} = \frac{1}{2} \left( \frac{\partial U_i}{\partial x_j} + \frac{\partial U_j}{\partial x_i} \right)$$

(12.1)

The inclusion of this term allows the model to adjust its length scale to already resolved scales in the flow and thereby provide a low enough eddy viscosity to allow the model to operate in ‘LES’ mode.

The SAS approach has the advantage that the RANS part of the model is unaffected by the grid spacing and will therefore not allow a deterioration of model accuracy as seen in DES in regions of refined grid but insufficient flow instability. However, in cases where the flow instability is not strong enough, the SAS will remain in RANS mode and will not produce unsteady structures. While this is often a sign that the RANS model is still reasonably capable of handling the flow, it is a limitation if unsteady information is required (for example, in acoustics). In such cases, the internal interface option of the ELES implementation can be applied to convert modeled turbulence into resolved turbulence (see Internal Interface Without LES Zone in the Theory Guide).

12.2.2.3. Detached Eddy Simulation (DES)

The DES model (see Detached Eddy Simulation (DES) in the Theory Guide) achieves the switch between RANS and LES by a comparison of the turbulent length scale $L_T$ with the grid spacing (maximum of cell
edge). The model selects the minimum of both and thereby switches between RANS and LES mode by replacing $\varepsilon$ in the $k$-equation by:

$$
\varepsilon = \frac{k^{3/2}}{L_t} \rightarrow \varepsilon = \min\left(\frac{k^{3/2}}{L_t}, c_{DES} \Delta_{\text{max}}\right)
$$

(12.2)

Once the model selects the grid spacing as the minimum, the model is operating in ‘LES’ mode.

The grid spacing enters explicitly into the DES model. This can affect the RANS solution in regions, where the grid is between RANS and LES resolution (so-called ‘gray zones’ in DES) and/or where the flow instability is not strong enough to generate LES structures. Another issue to consider with DES is the problem of ‘grid-induced-separation’ (GIS). It occurs if the grid for an attached wall boundary layer flow is refined to a point where the DES limiter becomes active and affects the RANS solution. However, in such situations, the flow instability is not strong enough to balance the reduced RANS content by resolved turbulence. This will typically result in an artificial flow separation at the location of grid refinement. It typically happens if $\Delta_{\text{max}} < \delta$ ($\delta$ being the boundary layer thickness). Remedies for this situation have been proposed by Menter et al. who recommended using the F1 and F2 blending functions of the SST-DES model to shield the boundary layers from the DES limiter. Later, alternative blending functions for the same purpose have been proposed by Spalart et al. ([86] (p. 2561)) – resulting in the terminology Delayed DES (DDES). The DDES model as originally proposed for the Spalart-Allmaras model provided limited protection against GIS for two-equation models such as SST and $k$-$\varepsilon$. Therefore, the DDES function has been re-calibrated for the SST and $k$-$\varepsilon$ models and is now the recommended choice and the default setting when using these models.

A further refinement is provided by the Improved DDES (IDDES) formulation of Strelets et al. ([91] (p. 2562)), which extends the LES zone of the model to the outer part of wall boundary layers. This allows the simulation of wall boundary layers in Wall-Modeled LES (WMLES) mode. In this model, the IDDES model is applied like a LES model, typically with the specification of unsteady inlet conditions. The grid resolution requirements for WMLES are much less stringent than for LES.

All of the above shielding function variants are available in ANSYS Fluent. For the Spalart-Allmaras model, the original DDES shielding function is used. For the $k$-$\varepsilon$ and the SST models, the DDES function has been re-calibrated for better boundary layer protection. The re-calibrated DDES function is the default selection and is recommended over the use of the F1-SST or F2-SST functions for the SST model. Despite the potential difficulties in the application of hybrid methods, they have the potential to greatly expand the usage of Scale-Resolving Simulation models for engineering applications, as they avoid the excessive resolution required by LES for wall boundary layers. IDDES in WMLES mode is an advanced option and should only be used if you are familiar with the original literature and the grid requirements for this model.

### 12.2.2.4. Zonal Modeling and Embedded LES (ELES)

As pointed out in the previous sections, hybrid models rely on flow instabilities to generate turbulent structures in large separated regions without the explicit introduction of unsteadiness through the boundary conditions. However, there are situations, where such instabilities are not present or are not reliable to serve this purpose. In such cases, it is desirable to apply RANS and the LES models in pre-defined zones and provide clearly defined interfaces between them. At these interfaces, the modeled turbulent kinetic energy from the upstream RANS model is converted explicitly to resolved scales at an internal boundary to the LES zone. The LES zone can then be limited to the region of interest where unsteady results are required. ELES is available in ANSYS Fluent and allows the combination of most RANS model with classical LES models. It is important to emphasize that in this mode, a full LES resolution is required within the LES zone. In the LES zone, using the WALE model is recommended (see Wall-Adapting Local Eddy-Viscosity (WALE) Model in the Theory Guide).
12.2.3. Grid Resolution SRS Models

Grid Resolution SRS models are discussed in the following sections:

12.2.3.1. Wall Boundary Layers
12.2.3.2. Free Shear Flows

12.2.3.1. Wall Boundary Layers

For a wall-resolved LES, it is typically recommended to use a mesh with a grid spacing scaling with \( \Delta x^+ \approx 40, \Delta y^+ \approx 1, \Delta z^+ \approx 20 \) where \( x \) is the streamwise, \( y \) the wall normal and \( z \) the spanwise direction (for example, channel flow). However, in complex applications, the distinction between streamwise and spanwise direction is not feasible and then \( \Delta x^+ = 20, \Delta y^+ = 1, \Delta z^+ = 20 \) would be required. This scaling demonstrates the strong Reynolds number dependency of the LES approach for wall bounded flows.

For the IDDES model in WMLES mode, the above requirements can be relaxed. The grid spacing no longer scale with the wall friction, but with the boundary layer thickness \( \delta \). It is recommended that you use \( \Delta x \approx \Delta z = (0.05 - 0.1) \cdot \delta \). The wall normal resolution should be like for a finely resolved RANS simulation, meaning a near wall resolution of \( \Delta y^+ \approx 1 \) and around 30 nodes inside the boundary layer.

The other hybrid models, SAS and DDES, require near wall resolution as in the underlying RANS models, as the boundary layers are covered in RANS mode. For the DDES (and the IDDES model run in DDES mode) model, Grid Induced Separation (GIS) may occur when not using the SST-F2 shielding function for \( \Delta x_{\text{max}} < \delta \). For the SST-F2 function the value is more \( \Delta x_{\text{max}} < 0.1 \cdot \delta \). This does however to a certain extent depend on the pressure gradient. Note however, that the SST-F2 function can reduce the effectiveness of the DDES model to switch into scale-resolving mode.

12.2.3.2. Free Shear Flows

For free shear flows, it is difficult to provide general recommendations, as there are many different flow scenarios. The current recommendation is therefore based on the most common (and most frequent) free shear flow – a turbulent mixing layer. It will not necessarily apply to other free shear flows like jets and you are advised to perform tests as to the optimal resolution of your specific flow.

For free shear flows and SRS models, one should aim for uniform isotropic cells (all edges have similar length). The shear layer should be covered by \( \sim 10-20 \) cells. As the layer thickness is often hard to estimate, one can also look at the ratio

\[
R_i = \frac{L_i}{\Delta_{\text{max}}}, \quad L_i = \frac{k^{3/2}}{\varepsilon} = \frac{k^{1/2}}{0.09 \omega}
\]

(12.3)

Where \( \Delta_{\text{max}} \) is the maximum cell edge length. It is available in ANSYS CFD-Post for all turbulence models. This estimate should be based on the RANS solution and not on the SAS/DES solution for the given flow! The above requirement for the mixing layer translates into:

\[ R_i > 5 - 10 \]

(12.4)

In these estimates, 10 cells across the layer (or \( R_i = 5 \)) is truly a lower limit. The higher values of 20 cells and \( R_i = 10 \) are much safer.
12.2.4. Numerics Settings for SRS Models

For Scale-Resolving Simulations (SRS), specific discretization and solver settings are required to achieve optimal accuracy with minimal numerical effort. The recommendations given below should be considered as a starting point for your specific flow application and are not generic, but problem dependent. The recommendations are based on incompressible, single phase flow without chemical reactions or other complex additional physics. In case your simulation features additional complex physical effects, it requires adjusting the recommended solver settings accordingly. In most cases, this will mean that a higher effort must be invested into the coupling of the equations (for example lower time step, reduced under-relaxation, higher iteration count, smaller residuals), in order to avoid a de-coupling of different physical phenomena.

For SRS models, it is generally recommended to use the pressure-based solver, as it offers optimized schemes for resolving turbulence relative to the density based solver.

For Scale-Resolving Simulations, optimal numerics settings are essential for achieving accurate results in an acceptable time frame. The reason is that at the SRS models operate at the resolution limit of the provided grid where the smallest scales are of the order of the grid spacing and the time resolution. Numerics settings therefore have to be chosen to provide an optimal balance between accuracy and robustness.

It is generally recommended to initialize the solution from a (reasonably) converged RANS simulation.

12.2.4.1. Time Discretization

For Scale-Resolving Simulations, the resolution of the turbulent structures in time is essential for the success of the simulation. This is, to the largest extent, defined by the selected time step. As the SRS model is operating at the grid limit, you should select a time step that ensures a Courant-Friedrichs-Levy (CFL) number of

\[ CFL = \frac{U \Delta t}{\Delta x} < 1 \]  

The CFL number is computed by the solver and can be checked based on an initial RANS simulation, for example. It is important to emphasize that this is not a numerical limit and that the solver will be able to sustain much larger CFL numbers. In complex applications, there will always be limited regions of fine cells or large velocities and you should not restrict the CFL number based on such zones. The recommendation of \( CFL = 1 \) should be applied in the main SRS region in combination with a uniform isotropic grid. It is recommended that you vary the time step for each type of application and explore its optimal value. This can substantially save on computing costs.

The time derivative should be computed by the Second Order Implicit option. (See User Inputs for Time-Dependent Problems (p. 1463) for guidelines on setting solution parameters for transient calculations in general.)

12.2.4.2. Spatial Discretization

For SRS models, it is important to minimize the numerical dissipation of the scheme in order to avoid damping of the smallest scales by numerical dissipation. For spatial discretization, the choice is between the Central Difference (CD) scheme (see Central-Differencing Scheme in the Theory Guide) and the Bounded Central Difference scheme (BCD) (see Bounded Central Differencing Scheme in the Theory Guide). The Central Difference scheme is the least dissipative and provides the highest resolution accuracy for the smallest scales. Especially for aero-acoustics simulations, where the spectral content at higher frequencies can be important, this is a desirable feature. However, Central Difference schemes are prone...
to solution oscillations (checker boarding) in the velocity field. When using the Central Difference scheme, it is therefore important to provide a high quality mesh (no mesh jumps, isotropic cells and high resolution in critical zones) and to avoid large time steps (the CFL number should be smaller than 1 in the main SRS region). It is recommended that you visually monitor the solution regularly in order to avoid wasting computational resources. In case oscillations appear, the choice is to: improve the mesh; reduce the time step; or to switch to the slightly more dissipative, but also more robust Bounded Central Difference scheme. In many complex applications, the Bounded Central Difference Scheme is the numerics option of choice. It typically provides sufficiently low dissipation to allow the turbulent structures to evolve, but, at the same time, is robust enough to handle non-optimal grids as they are typically encountered in industrial simulations. In addition, the Bounded Central Difference scheme is also suitable for hybrid methods like SAS and DES, and will provide stable solutions in RANS regions, with highly stretched grids and with a CFL number larger than 1. For ELES, the numerical scheme in the LES zone can be selected independently from the settings in the RANS zone. The RANS region can then be computed with standard higher order upwind schemes and the LES zone can be covered by either the Central Difference scheme or the Bounded Central Difference scheme.

For gradient discretization, it is recommended that you select the Least Squares Cell Based option, or the Green-Gauss Node Based option, to ensure a second order interpolation on non-orthogonal grids. For pressure interpolation, it is recommended that you use the second order scheme, or the body-force-weighted scheme. Due to its higher dissipation, the PRESTO! scheme (see Pressure Interpolation Schemes in the Theory Guide) can result in a delayed formation or damping of turbulent structures. It is therefore not recommended for SRS.

12.2.4.3. Iterative Scheme

The selection of the iterative scheme will mostly affect the computational costs as the cost per iteration between these methods is rather different. However, recommendations are not straightforward, as the higher cost per iteration of a scheme can be offset by faster convergence within the time step.

The fastest scheme is the Non-Iteration Time Advancement (NITA) scheme (see Non-Iterative Time-Advancement Scheme in the Theory Guide as well as Setting Solution Controls for the Non-Iterative Solver (p. 1420)). This scheme typically works well for limited LES zones and high quality meshes. It is also important to ensure a low time step of a CFL number below 1. For the NITA scheme, all explicit under-relaxation factors are, by default, set equal to one. With NITA, it has slight advantages to use the fractional step method if there is no involvement of more complex physics, when otherwise the PISO scheme can be more beneficial.

In case the application is too complex for the NITA scheme to provide a solution, the iterative SIMPLEx (SIMPLE vs. SIMPLEC (p. 1415)) or PISO (PISO (p. 1416)) schemes are the next possible option. They should be preferred relative to the SIMPLE scheme, as they show faster convergence per time step and can be run with more aggressive under-relaxation (higher values equal to 1 or close to 1). If such settings prevent convergence within the time step, then check if your time step is small enough for maintaining CFL numbers below 1 in the SRS region – if not, then try reducing $\Delta t$. If this is not possible, or does not lead to satisfactory convergence, then reduce the under-relaxation factors to values between the default settings and 1. For skewed meshes or meshes with problematic quality, the reduction of explicit relaxation factor for pressure correction down to 0.7 from 1 can be very helpful.

12.2.4.3.1. Convergence Control

The convergence criterion within each time step will strongly affect solution costs, as a low criterion will result in an increased number of iterations. It is not possible to provide general recommendations, as the required residual depends on the application. The most relevant residual in the SRS models is
the continuity residual. It should be converged by approximately 2 orders of magnitude per time step for a CFL number \(~ 1\). This should be achievable with around 5-10 maximum iterations per time step for flows involving no other physical models. Be sure to check the impact of convergence on your solution to ensure that the residual is reduced to a level consistent with your problem.

For simulations with small CFL values, the **Extrapolate variables** option (available in the Run Calculation Task Page (p. 2269)) can be very beneficial. This can substantially reduce the number of iterations within the time step up to 40% when the convergence control is based on the convergence criteria.

In case your simulation requires the combination of additional physical models, such as combustion or multiphase, a reduction of the under-relaxation factors might be required. In this case, the number of maximum iterations per time step can be increased to achieve the desired residual reduction.

For hybrid RANS/LES simulations, such as the SAS and DES models, there can be situations where the RANS portion of the flow limits convergence (for example, due to poor grid quality). In such cases, the application of the coupled solver should be considered. For the coupled pressure-based solver, each iteration is typically more expensive than for the SIMPLEC algorithm, but this is at least partly offset by faster convergence. The recommendations concerning residuals are similar to the SIMPLEC method, but the maximal number of iterations can be reduced to values as low as 2-5 for highly unstable flows, and 5-10 for more sensible flows and acoustics simulations.

### 12.2.5. Model Hierarchy

As discussed, turbulence modelling is a balance between accuracy and cost. The recommendation is to use RANS models as much as possible and as long as they provide the accuracy required for the simulation. RANS models will remain the workhorse of turbulence modelling for many years to come. Within the RANS family, eddy-viscosity models are typically sufficient for most engineering flow simulations. The application of RSM is only recommended for flows that are known to systematically benefit from their usage and justify the increase in computing power.

In cases where steady RANS or URANS models cannot provide the accuracy or unsteady information required, it is recommended that you switch to the SAS approach. It is relatively forgiving in terms of the grid resolution and will not deteriorate the results in case of insufficient resolution in the unsteady zone. The SAS model will only provide scale-resolution if a strong flow instability is present. Visual inspection (using iso-surfaces of the Q criterion) will quickly allow a judgment if the model provides sufficient unsteadiness and resolution relative to the grid spacing. In such cases, the internal interface option of the ELES implementation can be applied to convert modeled turbulence into resolved turbulence (see Internal Interface Without LES Zone in the Theory Guide).

DDES (DES is not recommended) models can allow the formation of unsteadiness even for cases where SAS remains stable. DDES does require a more carefully crafted grid in the LES zone due to the DES grid influence on the RANS solution. For the SST-DES model, use the default DDES blending function for shielding.

ELES is recommended in cases where limited zones with high accuracy requirements are embedded inside a larger RANS zone. At the interface between the RANS and the LES zone, unsteady turbulence is generated either by the Vortex Method or the Spectral Synthesizer. For wall bounded flows, the ELES method requires a very fine near wall resolution in the LES zone.

Pure LES should only be applied to free shear flows (for example, combustion chambers without wall influence, etc.) or to very limited domains using meshes with fine LES near wall resolution. It is important to be aware of the strong increase of grid resolution requirements with Reynolds number for wall bounded flows. For wall boundary layers at higher Reynolds numbers, the IDDES model can be run in WMLES mode – meaning with specified unsteady inlet conditions.
12.3. Steps in Using a Turbulence Model

When your ANSYS Fluent model includes turbulence you need to activate the relevant model and options, and supply turbulent boundary conditions. These inputs are described in this section.

The procedure for setting up a turbulent flow problem is described below. (Note that this procedure includes only those steps necessary for the turbulence model itself; you will need to set up other models, boundary conditions, etc. as usual.)

1. To activate one of the turbulence models, select either Spalart-Allmaras, k-epsilon, k-omega, Transition k-kl-omega, Transition SST, Reynolds Stress, Scale-Adaptive Simulation (SAS), Detached Eddy Simulation (DES), or Large Eddy Simulation (LES) under Model in the Viscous Model Dialog Box (Figure 12.2: The Viscous Model Dialog Box (p. 710)).

   ![Models → Viscous → Edit...](image-url)
If you choose the k-epsilon model, select either Standard, RNG, or Realizable under the k-epsilon Model. If you choose the k-omega model, select Standard or SST under k-omega Model.

**Important**

The Detached Eddy Simulation (DES) and the Large Eddy Simulation (LES) models are available only for 3D cases.

2. If the flow involves walls, and you are using one of the k-ε models or the RSM, choose one of the following options for the Near-Wall Treatment in the Viscous Model dialog box:

   - **Standard Wall Functions**
• **Scalable Wall Functions**

• **Non-Equilibrium Wall Functions**

• **Enhanced Wall Treatment**

• **User-Defined Wall Functions**

For more information about these near-wall options, see *Near-Wall Treatments for Wall-Bounded Turbulent Flows* in the *Theory Guide*. By default, the standard wall function is enabled.

For more information about the automatically defined near-wall treatment for the Spalart-Allmaras model, see *LES Near-Wall Treatment* in the *Theory Guide*.

For more information about the automatically defined near-wall treatment for the $k$-$\omega$ model, see *Wall Boundary Conditions* in the *Theory Guide*.

For more information about the automatically defined near-wall treatment for the LES model, see *Inlet Boundary Conditions for the LES Model* in the *Theory Guide*.

3. Enable the appropriate turbulence modeling options in the **Viscous Model** dialog box. See *Setup Options for All Turbulence Modeling* (p. 733)

4. Specify the boundary conditions for the solution variables.

   **Boundary Conditions**

   See *Defining Turbulence Boundary Conditions* (p. 741) for details.

5. Specify the initial guess for the solution variables.

   **Solution Initialization**

   See *Providing an Initial Guess for $k$ and $\varepsilon$ (or $k$ and $\omega$)* (p. 744) for details. Note that Reynolds stresses are automatically initialized using $k$, and therefore need not be initialized explicitly.

### 12.4. Setting Up the Spalart-Allmaras Model

If you choose the Spalart-Allmaras model, the following options are available:

• vorticity-based production (*Vorticity- and Strain/Vorticity-Based Production* (p. 736))

• strain/vorticity-based production (*Vorticity- and Strain/Vorticity-Based Production* (p. 736))

• viscous heating (always activated for the density-based solvers) (*Including the Viscous Heating Effects* (p. 734))

• curvature correction (*Including the Curvature Correction for the Spalart-Allmaras and Two-Equation Turbulence Models* (p. 734))
12.5. Setting Up the $k$-$\varepsilon$ Model

For additional information, see the following sections:
12.5.1. Setting Up the Standard or Realizable $k$-$\varepsilon$ Model
12.5.2. Setting Up the RNG $k$-$\varepsilon$ Model

12.5.1. Setting Up the Standard or Realizable $k$-$\varepsilon$ Model

If you choose the standard $k$-$\varepsilon$ model or the realizable $k$-$\varepsilon$ model, the following options are available:

- viscous heating (always activated for the density-based solvers) (Including the Viscous Heating Effects (p. 734))
- inclusion of buoyancy effects on $\varepsilon$ (see Effects of Buoyancy on Turbulence in the $k$-$\varepsilon$ Models in the Theory Guide)
- inclusion of curvature correction (Including the Curvature Correction for the Spalart-Allmaras and Two-Equation Turbulence Models (p. 734))
- inclusion of compressibility correction (Including the Compressibility Correction Option (p. 735))
- inclusion of production limiters (Including Production Limiters for Two-Equation Models (p. 735))
12.5.2. Setting Up the RNG \( k-\varepsilon \) Model

If you choose the RNG \( k-\varepsilon \) model, the following options are available:

- differential viscosity model (Differential Viscosity Modification (p. 737))
- swirl modification (Swirl Modification (p. 737))
- viscous heating (always activated for the density-based solvers) (Including the Viscous Heating Effects (p. 734))
- inclusion of buoyancy effects on \( \varepsilon \) (see Effects of Buoyancy on Turbulence in the \( k-\varepsilon \) Models in the Theory Guide)
- inclusion of curvature correction (Including the Curvature Correction for the Spalart-Allmaras and Two-Equation Turbulence Models (p. 734))
- inclusion of compressibility correction (Including the Compressibility Correction Option (p. 735))
inclusion of production limiters (Including Production Limiters for Two-Equation Models (p. 735))

**Figure 12.5: The Viscous Model Dialog Box Displaying the RNG k-ε Model**

For all $k$-$\varepsilon$ models, one of the following near-wall treatments must be selected (see Near-Wall Treatments for Wall-Bounded Turbulent Flows in the Theory Guide):

- standard wall functions
- scalable wall functions
- non-equilibrium wall functions
• enhanced wall treatment
• user-defined wall functions

If you choose the enhanced wall treatment, the following options are available:

• pressure gradient effects (Including Pressure Gradient Effects (p. 738))
• thermal effects (Including Thermal Effects (p. 738))

If you choose the user-defined wall functions near-wall treatment, hook your UDF under **Law of the Wall**, as shown in Figure 12.4: The Viscous Model Dialog Box Displaying the Standard k-ω Model(p. 713).

### 12.6. Setting Up the k-ω Model

For additional information, see the following sections:
12.6.1. Setting Up the Standard k-ω Model
12.6.2. Setting Up the Shear-Stress Transport k-ω Model

#### 12.6.1. Setting Up the Standard k-ω Model

If you choose the standard $k-\omega$ model, the following options are available:

• low-Re corrections (Low-Re Corrections (p. 737))
• shear flow corrections (Shear Flow Corrections (p. 737))
• turbulence damping (available with the VOF and Mixture models and the Eulerian multiphase model when using the immiscible fluid model) (Turbulence Damping (p. 737))
• viscous heating (always activated for the density-based solvers) (Including the Viscous Heating Effects (p. 734))
• inclusion of curvature correction (Including the Curvature Correction for the Spalart-Allmaras and Two-Equation Turbulence Models (p. 734))
• inclusion of compressibility correction (Including the Compressibility Correction Option (p. 735))
• inclusion of production limiters (Including Production Limiters for Two-Equation Models (p. 735))
• a scale-resolving simulation option: Scale-Adaptive Simulation (Setting Up Scale-Adaptive Simulation (SAS) Modeling (p. 722))
The \( k-\omega \) models use enhanced wall functions as the near-wall treatment (see Enhanced Wall Treatment for Momentum and Energy Equations in the Theory Guide).

### 12.6.2. Setting Up the Shear-Stress Transport \( k-\omega \) Model

If you choose the shear-stress transport \( k-\omega \) model, the following options are available:

- low-Re corrections ([Low-Re Corrections](p. 737))
- turbulence damping (available with the VOF and Mixture models and the Eulerian multiphase model when using the immiscible fluid model) ([Turbulence Damping](p. 737))
- viscous heating (always activated for the density-based solvers) ([Including the Viscous Heating Effects](p. 734))
- inclusion of curvature correction ([Including the Curvature Correction for the Spalart-Allmaras and Two-Equation Turbulence Models](p. 734))
- inclusion of compressibility correction ([Including the Compressibility Correction Option](p. 735))
• inclusion of production limiters (Including Production Limiters for Two-Equation Models (p. 735))

• inclusion of the Intermittency Transition model

**Figure 12.7: The Viscous Model Dialog Box Displaying the SST $k-\omega$ Model**

12.7. Setting Up the Transition $k$-$kl$-$\omega$ Model

If you choose the Transition $k$-$kl$-$\omega$ model, it is not necessary to modify any of the model constants.

12.8. Setting Up the Transition SST Model

If you choose the Transition SST model, the following options are available:

• roughness correlation (Transition SST and Rough Walls in the Theory Guide)

• viscous heating (always activated for the density-based solvers) (Including the Viscous Heating Effects (p. 734))

• inclusion of curvature correction (Including the Curvature Correction for the Spalart-Allmaras and Two-Equation Turbulence Models (p. 734))

• inclusion of production limiters (Including Production Limiters for Two-Equation Models (p. 735))
• scale-resolving simulation options: either Scale-Adaptive Simulation (Setting Up Scale-Adaptive Simulation (SAS) Modeling (p. 722)) or Detached Eddy Simulation (Setting Up DES with the Transition SST Model (p. 728))

**Figure 12.8: The Viscous Model Dialog Box for the Transition SST Model**

You can customize your transition correlations, which are used in conjunction with the Transition SST model. The user-defined functions that you can hook are:

- transition length function (**F_length**).
- critical momentum thickness Reynolds number (**Re_thetac**).
- transition onset momentum thickness Reynolds number (**Re_thetat**).

For detailed information about the transition correlation UDFs, see **DEFINE_TRANS UDFs** in the **UDF Manual**.

### 12.9. Setting Up the Intermittency Transition Model

The Intermittency Transition model is available as an option for the following turbulence models:

- SST $k-\omega$ model
• Scale-Adaptive Simulation with SST
• Detached Eddy Simulation with SST

To apply it in combination with one of these turbulence models, you must enable the **Intermittency Transition Model** option from the Options group box in the **Viscous Model** dialog box.

**Figure 12.9: The Intermittency Transition Model in Combination with the SST k-ω Model**

After you have enabled the Intermittency Transition model, the additional option **Include Crossflow Transition** will be available. This additional option allows you to include the effects of crossflow instability.

### 12.10. Setting Up the Reynolds Stress Model

If you choose the RSM, the following submodels are available:

• linear pressure-strain model (see **Linear Pressure-Strain Model** in the Theory Guide)
• quadratic pressure-strain model (**Quadratic Pressure-Strain Model (p. 739)**)
• Stress-Omega (**Stress-Omega Pressure-Strain (p. 739)**)
The following Reynolds-stress options are available:

- wall boundary conditions for the Reynolds stresses from the $k$ equation (Solving the $k$ Equation to Obtain Wall Boundary Conditions (p. 738)) for the linear and quadratic pressure-strain models

- wall reflection effects on Reynolds stresses (Including the Wall Reflection Term (p. 738)) for the linear pressure-strain model

Other options that are available based on your case setup includes:

- viscous heating (always activated for the density-based solvers) (Including the Viscous Heating Effects (p. 734))

- inclusion of compressibility correction (Including the Compressibility Correction Option (p. 735))
• inclusion of buoyancy effects on $\varepsilon$ (see Effects of Buoyancy on Turbulence in the $k-\varepsilon$ Models in the Theory Guide)

For the Reynolds stress model, the following near-wall treatments are available (see Near-Wall Treatments for Wall-Bounded Turbulent Flows in the Theory Guide):

• standard wall functions
• scalable wall functions
• non-equilibrium wall functions
• enhanced wall treatment

If wall boundary conditions for the Reynolds stresses from the $k$ equation and/or wall reflection effects on Reynolds stresses are/is selected, then all the above near-wall treatments are available for selection.

If you choose the enhanced wall treatment, the following options are available:

• pressure gradient effects (Including Pressure Gradient Effects (p. 738))
• thermal effects (Including Thermal Effects (p. 738))

If the quadratic pressure-strain model is selected, then you can set either the standard wall functions or the non-equilibrium wall functions.

If Stress-Omega is selected, you cannot select any near-wall treatments and should use an LRN mesh. You do have the option of selecting any or all of the following $k-\omega$ and scale-resolving simulation options:

• low-Re corrections (Low-Re Corrections (p. 737))
• shear flow corrections (Shear Flow Corrections (p. 737))
• Scale-Adaptive Simulation (Setting Up Scale-Adaptive Simulation (SAS) Modeling (p. 722))

Scale-Adaptive Simulation (SAS) modeling is an approach for the simulation of unsteady turbulent flows, and can be applied in combination with most $\omega$-based URANS turbulence models. To apply it in combination with the SST $k-\omega$ turbulence model, you can simply select **Scale-Adaptive Simulation (SAS)** from the **Model** list in the **Viscous Model** dialog box.
You can also apply SAS in combination with the following $\omega$-based URANS models: the Standard $k-\omega$ model, the Transition SST model, and the $\omega$-based Reynolds stress model (RSM). Simply select the appropriate Model and then enable the Scale-Adaptive Simulation (SAS) option in the Scale-Resolving Simulation Options group box. For an example, see Figure 12.13: Scale-Adaptive Simulation (SAS) in Combination with the Transition SST Model (p. 724).
Figure 12.13: Scale-Adaptive Simulation (SAS) in Combination with the Transition SST Model

Note that for SAS modeling, the *Bounded Central Differencing* scheme (available in the *Solution Methods* task page) is recommended for momentum discretization, and is the default setting.

12.12. Setting Up the Detached Eddy Simulation Model

When using the Detached Eddy Simulation (DES) model, the following underlying RANS turbulence models can be used:

- Spalart-Allmaras
- Realizable $k-\varepsilon$
- SST $k-\omega$
- Transition SST

Note that for the DES model, the *Bounded Central Differencing* scheme (available in the *Solution Methods* task page) is recommended for momentum discretization, and is the default setting.

For additional information, see the following sections:
12.12.1. Setting Up DES with the Spalart-Allmaras Model
12.12.2. Setting Up DES with the Realizable $k-\varepsilon$ Model
12.12.3. Setting Up DES with the SST $k-\omega$ Model
12.12.4. Setting Up DES with the Transition SST Model

12.12.1. Setting Up DES with the Spalart-Allmaras Model

To set up a Detached Eddy Simulation with the Spalart-Allmaras model, select **Detached Eddy Simulation (DES)** from the **Model** list in the **Viscous Model** dialog box and then select **Spalart-Allmaras** from the **RANS Model** list.

ANSYS Fluent uses Equation 4.236 (in the **Theory Guide**) to compute the value of the length scale $\bar{d}$ for the Spalart-Allmaras model. By default, the empirical constant $C_{des}$ is set to 0.65. You can change its value in the **Cdes** field under **Model Constants**. The following options are available for this model:

- vorticity-based production (**Vorticity- and Strain/Vorticity-Based Production** (p. 736))
- strain/vorticity-based production (**Vorticity- and Strain/Vorticity-Based Production** (p. 736))
- delayed DES (**Delayed Detached Eddy Simulation (DDES)** (p. 736))
- viscous heating (always activated for the density-based solvers) (**Including the Viscous Heating Effects** (p. 734))
- inclusion of curvature correction (**Including the Curvature Correction for the Spalart-Allmaras and Two-Equation Turbulence Models** (p. 734))
Additionally, you can perform the following DES-specific function by using the \texttt{/define/models/viscous/detached-eddy-simulation?} text command:

- Modify only the length scales that appear in the destruction term in $v_f$ equation (the default is to modify all length scales within the $v_f$ equation)

### 12.12.2. Setting Up DES with the Realizable $k$-$\epsilon$ Model

To set up a Detached Eddy Simulation with the Realizable $k$-$\epsilon$ model, select Detached Eddy Simulation (DES) from the Model list in the Viscous Model dialog box and then select Realizable $k$-epsilon from the RANS Model list.

The model-specific options for DES with the Realizable $k$-$\epsilon$ model are the following:

- delayed DES (Delayed Detached Eddy Simulation (DDES) (p. 736))
- viscous heating (always activated for the density-based solvers) (Including the Viscous Heating Effects (p. 734))
- inclusion of compressibility correction (Including the Compressibility Correction Option (p. 735))
The model constant $C_{\text{des}}$ is set to 0.61 for the Realizable $k-\varepsilon$ model (see DES with the Realizable $k-\varepsilon$ Model in the Theory Guide).

**Figure 12.15: The Viscous Model Dialog Box Displaying Options for DES with the Realizable $k-\varepsilon$ Model**

12.12.3. Setting Up DES with the SST $k-\omega$ Model

To set up a Detached Eddy Simulation with the SST $k-\omega$ model, select **Detached Eddy Simulation (DES)** from the **Model** list in the **Viscous Model** dialog box and then select **SST $k$-omega** from the **RANS Model** list.

The model-specific options that you can select for DES with the SST $k-\omega$ model are the following:

- low-Re corrections $k-\omega$ option ([Low-Re Corrections](p. 737))
- delayed DES ([Delayed Detached Eddy Simulation (DDES](p. 736))
- viscous heating (always activated for the density-based solvers) ([Including the Viscous Heating Effects](p. 734))
- inclusion of curvature correction ([Including the Curvature Correction for the Spalart-Allmaras and Two-Equation Turbulence Models](p. 734))
- inclusion of production limiters ([Including Production Limiters for Two-Equation Models](p. 735))
• inclusion of the Intermittency Transition model

• Shielding functions, F1, F2, DDES (Delayed DES) and IDDES (Improved Delayed DES) (Shielding Functions for the SST Detached Eddy Simulation Model (p. 740))

The model constant $C_{des}$ is set to 0.61 for the SST $k$-$\omega$ RANS model (see DES with the SST $k$-$\omega$ Model in the Theory Guide).

**Figure 12.16: The Viscous Model Dialog Box Displaying Options for DES with the SST k-$\omega$ Model**

![Viscous Model Dialog Box](image)

### 12.12.4. Setting Up DES with the Transition SST Model

To set up a Detached Eddy Simulation with the Transition SST model for a transient case, select Transition SST from the Model list in the Viscous Model dialog box and then enable the Detached Eddy Simulation (DES) option in the Scale-Resolving Simulation Options group box.

For DES with the Transition SST model, you can choose to enable the Delayed DES option in the DES Options group box (see Delayed Detached Eddy Simulation (DDES) (p. 736) for details). When this option is enabled you can make a selection from the Shielding Functions list, as described in Shielding Functions for the SST Detached Eddy Simulation Model (p. 740).
12.13. Setting Up the Large Eddy Simulation Model

If you choose the LES model, the following subgrid-scale submodels are available (Subgrid-Scale Model (p. 739)):

- Smagorinsky-Lilly
- WALE
- WMLES
- WMLES S-Omega
- Kinetic-Energy Transport
The LES options that are available for the **Smagorinsky-Lilly** submodel are

- **Dynamic Stress**

- **Dynamic Energy Flux** (available only when the **Dynamic Stress** option is enabled)

- **Dynamic Scalar Flux**

The LES options that are available when the **Kinetic-Energy Transport** submodel is selected are **Dynamic Energy Flux** and **Dynamic Scalar Flux**.

The **Dynamic Fvar** option is available for all of the subgrid-scale submodels when **Non-Premixed Combustion** or **Partially Premixed Combustion** is selected in the Species Model Dialog Box (p. 1943). This option enables the dynamic mixture fraction variance model. See The Non-Premixed Model for LES in the **Theory Guide** for details.

### 12.14. Model Constants

It is also possible to modify the **Model Constants**, but this is not necessary for most applications. For more information about the constants, see [Spalart-Allmaras Model through Large Eddy Simulation (LES) Model](in the Theory Guide). Note that **C1-PS** and **C2-PS** are the constants $C_1$ and $C_2$ in the linear pressure-strain approximation of Equation 4.196 and Equation 4.197 (in the Theory Guide), and **C1’-PS**
and \( C_2' \)-PS are the constants \( C_1' \) and \( C_2' \) in Equation 4.198 (in the Theory Guide). \( C_1\)-SSG-PS, \( C_1'\)-SSG-PS, \( C_2\)-SSG-PS, \( C_3\)-SSG-PS, \( C_3'\)-SSG-PS, \( C_4\)-SSG-PS, and \( C_5\)-SSG-PS are the constants \( C_1 \), \( C_1^* \), \( C_2 \), \( C_3 \), \( C_3^* \), \( C_4 \), and \( C_5 \) in the quadratic pressure-strain approximation of Equation 4.207 (in the Theory Guide).

12.15. Setting Up the Embedded Large Eddy Simulation (ELES) Model

As described in Embedded Large Eddy Simulation (ELES) in the Theory Guide, the Embedded Large Eddy Simulation model is used when modeling a smaller embedded LES zone within a larger RANS computational domain. Recall that the interface between the upstream RANS zone and the LES zone must be defined (by assigning the interface to a velocity fluctuation algorithm). In addition, the interface between the LES zone and the downstream RANS zone must be considered.

This section describes how to set up the Embedded Large Eddy Simulation model.

1. In the Viscous Model dialog box, enable any RANS model (\( k-c \), \( k-\omega \) etc.), or you can select DES or SAS. The only RANS model not compatible with ELES is the Spalart-Allmaras model, as a one-equation model cannot provide the required turbulent length scale to the interface method.

   If a RANS model is selected, the model is applied globally to the computational domain, however, values for turbulence variables are frozen within the ELES region. The frozen state of the ELES zone is used to determine the flow conditions (for \( k-c \), \( k-\omega \) etc.) at the downstream LES-RANS zone interface. Note that this approach requires a fairly well converged global RANS solution to start with.

   If DES or SAS is used in the outer zone, these models are not frozen, but run in the background in the ELES region, obtaining proper flow conditions (for \( k-c \), \( k-\omega \) etc.) at the downstream LES-RANS zone interface.

2. For the specified fluid cell zone, enable LES Zone in the Fluid dialog box (Figure 12.19: Specifying an ELES Zone in the Fluid Dialog Box (p. 732)). This enables the Embedded LES tab in the Fluid dialog box.

   **Note**

   When DES or SAS is used for the global model, this and the next step can, but need not, be skipped. (Keep in mind the general limitations of DES in free, wall-independent flows.) If you choose to skip these steps, then proceed with step 4.

   The ELES Zone option will only appear in the Fluid dialog box if you select the Transient Solver. This must be done manually for RANS models.

3. In the Embedded LES tab, you can then specify the Embedded Subgrid Scale Model, and the Momentum Spatial Discretization.

   For the Embedded Subgrid Scale Model, the following subgrid-scale submodels are available (Subgrid-Scale Model (p. 739)):

   - Smagorinsky-Lilly
   - WALE
Dynamic Smagorinsky

WMLES

WMLES S-Omega

When the Smagorinsky-Lilly model is selected, you can specify a value for $C_s^r$ (see Smagorinsky-Lilly Model in the Theory Guide for details). Likewise, when the WALE model is selected, you can specify a value for $C_{wale}$ (or $C_w$, see Wall-Adapting Local Eddy-Viscosity (WALE) Model in the Theory Guide for details).

For the Momentum Spatial Discretization, the following options are available:

- Bounded Central Differencing
- Central Differencing

Figure 12.19: Specifying an ELES Zone in the Fluid Dialog Box

4. Select an appropriate interior interface and designate it as the RANS-LES interface, by selecting the boundary zone under Zones in the Boundary Conditions task page, and assign to rans-les-interface for the boundary Type. Click Edit... to display the RANS/LES Interface dialog box (Figure 12.20: Specifying a RANS/LES Interface (p. 733)), where you can assign a Zone Name, as well as the Fluctuating
**Velocity Algorithm**, and the **Number of Vortices**. The options for the **Fluctuating Velocity Algorithm** are:

- No Perturbations
- Spectral Synthesizer
- Vortex Method

For more information about these options, refer to **Inlet Boundary Conditions for the LES Model** in the **Theory Guide**.

Note that the **Number of Vortices** is the amount of vortices that the selected method distributes randomly over the face zone and uses to generate turbulent fluctuations. The value should be large enough to make sure there are no spots on the face zone that are unaffected by any vortex. Large numbers may slightly increase the CPU effort, but will not impair the results.

---

**Note**

The minimum advised number of vortices is approximately a quarter of the number of cell faces at the LES side of the interface.

---

**Figure 12.20: Specifying a RANS/LES Interface**

[Diagram showing RANS/LES interface settings]

If the RANS/LES interface is a non-conformal mesh interface, you can find the name of the interior zone that you want to change into a **rans-les-interface** zone in the **Mesh Interfaces Task Page** (p. 2172).

---

**Important**

It is recommended that the RANS-LES interface be situated in a region where there is no backflow.

---

**12.16. Setup Options for All Turbulence Modeling**

For more information about the various options available for the turbulence models, see **Spalart-Allmaras Model** through **Large Eddy Simulation (LES) Model** (in the **Theory Guide**). Instructions for activating these options are provided here.

For additional information, see the following sections:
12.16.1. Including the Viscous Heating Effects

12.16.2. Including Turbulence Generation Due to Buoyancy

12.16.3. Including the Curvature Correction for the Spalart-Allmaras and Two-Equation Turbulence Models

12.16.4. Including the Compressibility Correction Option

12.16.5. Including Production Limiters for Two-Equation Models

12.16.6. Including the Intermittency Transition Model

12.16.7. Vorticity- and Strain/Vorticity-Based Production

12.16.8. Delayed Detached Eddy Simulation (DDES)

12.16.9. Differential Viscosity Modification

12.16.10. Swirl Modification

12.16.11. Low-Re Corrections

12.16.12. Shear Flow Corrections

12.16.13. Turbulence Damping

12.16.15. Including Thermal Effects

12.16.16. Including the Wall Reflection Term

12.16.17. Solving the k Equation to Obtain Wall Boundary Conditions

12.16.18. Quadratic Pressure-Strain Model

12.16.19. Stress-Omega Pressure-Strain

12.16.20. Subgrid-Scale Model

12.16.21. Customizing the Turbulent Viscosity

12.16.22. Customizing the Turbulent Prandtl and Schmidt Numbers

12.16.23. Modeling Turbulence with Non-Newtonian Fluids

12.16.24. Including Scale-Adaptive Simulation with \( \omega \)-Based URANS Models

12.16.25. Including Detached Eddy Simulation with the Transition SST Model

12.16.26. Shielding Functions for the SST Detached Eddy Simulation Model

12.16.1. Including the Viscous Heating Effects

For information about including viscous heating effects in your model, see Inclusion of the Viscous Dissipation Terms in the Theory Guide and Solving Heat Transfer Problems (p. 759).

12.16.2. Including Turbulence Generation Due to Buoyancy

If you specify a non-zero gravity force (in the Operating Conditions Dialog Box (p. 2095)), and you are modeling a non-isothermal flow, the generation of turbulent kinetic energy due to buoyancy \( G_b \) in Equation 4.33 is, by default, always included in the \( k \) equation. However, ANSYS Fluent does not, by default, include the buoyancy effects on \( \varepsilon \).

To include the buoyancy effects on \( \varepsilon \), you must turn on the Full Buoyancy Effects option under Options in the Viscous Model Dialog Box (p. 1903).

This option is available for all three \( k-\varepsilon \) models and for the RSM.

12.16.3. Including the Curvature Correction for the Spalart-Allmaras and Two-Equation Turbulence Models

Eddy-viscosity models display an insensitivity to streamline curvature and system rotation, which play a significant role in many turbulent flows of practical interest, as described in Curvature Correction for the Spalart-Allmaras and Two-Equation Models in the Theory Guide. A modification to the turbulence production term is available to sensitize the following standard eddy-viscosity models to the effects of streamline curvature and system rotation:
• Spalart-Allmaras one-equation model
• Standard, RNG, and Realizable \( (k-\varepsilon) \) models
• Standard \( (k-\omega) \), SST and Transition SST
• Scale-Adaptive Simulation (SAS)
• Detached Eddy Simulation with SST (DES-SST), with Spalart-Allmaras (DES-SA), and with Realizable \( (k-\varepsilon) \) model (DES-rke).

Note that both the RNG and Realizable \( (k-\varepsilon) \) turbulence models already have their own terms to include rotational or swirl effects (see RNG Swirl Modification and Modeling the Turbulent Viscosity in the Theory Guide for more information). The curvature correction option should therefore be used with caution for these two models and is offered mainly for completeness for RNG and Realizable \( (k-\varepsilon) \).

Enable the **Curvature Correction** option under **Options** in the Viscous Model Dialog Box (p. 1903).

12.16.4. Including the Compressibility Correction Option

The **Compressibility Correction** option is available under **Options** in the Viscous Model Dialog Box (p. 1903) for most \( \varepsilon \)-based models, \( \omega \)-based models, and Reynolds stress models when the compressible form of the ideal gas law or the real-gas model is activated. This option can improve the prediction of free shear layers at high Mach numbers. See Model Enhancements (p. 700) for recommendations on when to use this option. For details about how this correction is implemented, see Effects of Compressibility on Turbulence in the \( k-\varepsilon \) Models and Compressibility Correction in the Theory Guide.

12.16.5. Including Production Limiters for Two-Equation Models

A disadvantage of standard two-equation turbulence models is the excessive generation of the turbulence energy, \( G_k \), in the vicinity of stagnation points. In order to avoid the buildup of turbulent kinetic energy in the stagnation regions, two formulations are available in order to limit the production term in the turbulence kinetic energy equations:

• Production Limiter (for details, see Equation 4.349 in the Fluent Theory Guide)
• Production Kato-Launder (for details, see Equation 4.353 in the Fluent Theory Guide)

Both these formulations can be accessed under **Options** in the Viscous Model dialog box. The **Production Limiter** model coefficient \( C_{lim} \) is called the **Production Limiter Clip Factor** and has a default value of 10. This value can be modified under **Model Constants** once the **Production Limiter** formulation is enabled.

You can use the following text commands to set the formulations:

• Production Limiter
  
  /define/models/viscous/turbulence-expert/production-limiter?[yes]

• Production Kato-Launder
  
  /define/models/viscous/turbulence-expert/kato-launder-model?[yes]

The **Production Limiter** is available for the following turbulence models:
• Standard, RNG, and Realizable \((k-\varepsilon)\) models

• Standard \((k-\omega)\), SST and Transition SST

• Scale-Adaptive Simulation (SAS)

• Detached Eddy Simulation with SST (DES-SST) and with Realizable \((k-\varepsilon)\) models (DES-rke)

By default, this limiter is enabled for all turbulence models based on the \(\omega\) equation.

The Production Kato-Launder formulation for the production term is available for the following turbulence models:

• Standard, and RNG \((k-\varepsilon)\) models

• Standard \((k-\omega)\), SST, and Transition SST

• Scale-Adaptive Simulation (SAS)

• Detached Eddy Simulation with SST (DES-SST)

The Kato-Launder formulation is enabled by default for the Transition SST model only.

12.16.6. Including the Intermittency Transition Model

The Intermittency Transition model is available for the SST \(k-\omega\) model, Scale-Adaptive Simulation with SST, and Detached-Eddy Simulation with SST. It can be included by enabling Intermittency Transition Model in the Options group box in the Viscous Model dialog box with the appropriate turbulence model selected.

When the Intermittency Transition Model option is enabled, the additional option Include Crossflow Transition is available. It allows you to include the effects of crossflow instability.

For details about the Intermittency Transition model, see Intermittency Transition Model in the Theory Guide.

12.16.7. Vorticity- and Strain/Vorticity-Based Production

For the Spalart-Allmaras model, you can choose either Vorticity-Based Production or Strain/Vorticity-Based Production under Spalart-Allmaras Production in the Viscous Model Dialog Box (p. 1903). If you choose Vorticity-Based Production, ANSYS Fluent will compute the value of the deformation tensor \(S\) using Equation 4.22 (in the Theory Guide); if you choose Strain/Vorticity-Based Production, it uses Equation 4.24 (in the Theory Guide).

(These options will not appear unless you have activated the Spalart-Allmaras model.)

12.16.8. Delayed Detached Eddy Simulation (DDES)

The Delayed DES option is recommended when using the DES model. This option preserves the RANS model throughout the boundary layer. For more information, see Detached Eddy Simulation (DES) in the Theory Guide.
12.16.9. Differential Viscosity Modification

The RNG turbulence model in ANSYS Fluent has an option of using a differential formula for the effective viscosity $\mu_{eff}$ (Equation 4.38 in the Theory Guide) to account for the low-Reynolds-number effects. To enable this option, the Differential Viscosity Model option under RNG Options in the Viscous Model Dialog Box (p. 1903) must be enabled.

**Important**

This option appears when you have activated the RNG $k$-$\varepsilon$ model.

12.16.10. Swirl Modification

After you have chosen the RNG model, the swirl modification takes effect, by default, for all three-dimensional flows and axisymmetric flows with swirl. The default swirl constant ($\alpha_s$ in Equation 4.40 in the Theory Guide) is set to 0.07, which works well for weakly to moderately swirling flows. However, for strongly swirling flows, you may need to use a larger swirl constant.

To change the value of the swirl constant, you must first enable the Swirl Dominated Flow option under RNG Options in the Viscous Model Dialog Box (p. 1903).

**Important**

This option will not appear unless you have activated the RNG $k$-$\varepsilon$ model.

12.16.11. Low-Re Corrections

If either of the $k$-$\omega$ models are used, you may enable a low-Reynolds-number correction to the turbulent viscosity by enabling the Low-Re Corrections option under k-omega Options in the Viscous Model dialog box. By default, this option is not enabled, and the damping coefficient ($\alpha^*$ in Equation 4.68 in the Theory Guide) is equal to 1.

12.16.12. Shear Flow Corrections

In the standard $k$-$\omega$ model, you also have the option of including corrections to improve the accuracy in predicting free shear flows. The Shear Flow Corrections option under the k-omega Options is enabled by default in the Viscous Model dialog box, as these corrections are included in the standard $k$-$\omega$ model [116] (p. 2563). When this option is enabled, ANSYS Fluent will calculate $f_{\beta}^*$ using Equation 4.78 (in the Theory Guide) and $f_{\beta}$ using Equation 4.85 (in the Theory Guide). If this option is disabled, $f_{\beta}^*$ and $f_{\beta}$ will be set equal to 1.

12.16.13. Turbulence Damping

In the standard or SST $k$-$\omega$ model, you have the option of including turbulence damping, which is required for the accurate modeling of the interfacial area. The Turbulence Damping option under k-omega Options is available for the VOF and Mixture models and also available with the Eulerian multiphase model when using the immiscible fluid model. When this option is enabled, you can set the Damping
Factor, which by default is set to 10. For a theoretical discussion about turbulence damping, refer to Turbulence Damping.

If the enhanced wall treatment is used, you may include the effects of pressure gradients by enabling the Pressure Gradient Effects option under the Enhanced Wall Treatment Options. When this option is enabled, ANSYS Fluent will include the coefficient $\alpha$ in Equation 4.321 (in the Theory Guide).

12.16.15. Including Thermal Effects

If the enhanced wall treatment is used, you may include thermal effects by enabling the Thermal Effects option under Enhanced Wall Treatment Options. When this option is enabled, ANSYS Fluent will include the coefficient $\beta$ in Equation 4.321 (in the Theory Guide). $\gamma$ will also be included in Equation 4.321 when the Thermal Effects option is enabled if the ideal gas law is selected for the fluid density in the Create/Edit Materials dialog box.

12.16.16. Including the Wall Reflection Term

If the RSM is used with the default model for linear pressure-strain, ANSYS Fluent will, by default, include the wall-reflection effects in the pressure-strain term. That is, ANSYS Fluent will calculate $\phi_{ij,w}$ using Equation 4.198 (in the Theory Guide) and include it in Equation 4.195 (in the Theory Guide). For the quadratic pressure-strain model, the wall-reflection effects are not required and are not included in the model.

---

Important

The empirical constants and the function $f'$ used in the calculation of $\phi_{ij,w}$ are calibrated for simple canonical flows such as channel flows and flat-plate boundary layers involving a single wall. If the flow involves multiple walls and the wall has significant curvature (for example, an axisymmetric pipe or curvilinear duct), the inclusion of the wall-reflection term in Equation 4.198 (in the Theory Guide) may not improve the accuracy of the RSM predictions. In such cases, you can disable the wall-reflection effects by turning off the Wall Reflection Effects under Reynolds-Stress Options in the Viscous Model Dialog Box (p. 1903).

---

12.16.17. Solving the k Equation to Obtain Wall Boundary Conditions

In the RSM, ANSYS Fluent, by default, uses the explicit setting of boundary conditions for the Reynolds stresses near the walls, with the values computed with Equation 4.225 (in the Theory Guide). The turbulent kinetic energy, $k$, is calculated by solving the $k$ equation obtained by summing Equation 4.192 (in the Theory Guide) for normal stresses. To disable this option and use the wall boundary conditions given in Equation 4.226 (in the Theory Guide), turn off the Wall BC from k Equation under the Reynolds-Stress Options in the Viscous Model dialog box.

---

Important

This option will not appear unless you have activated the Reynolds Stress model.
12.16.18. Quadratic Pressure-Strain Model

To use the quadratic pressure-strain model described in Quadratic Pressure-Strain Model (in the Theory Guide), enable the Quadratic Pressure-Strain Model option under Reynolds-Stress Options in the Viscous Model Dialog Box (p. 1903). (This option will not appear unless you have activated the RSM.) The following options are not available when the Quadratic Pressure-Strain Model is enabled:

- Wall Reflection Effects under Reynolds-Stress Options
- Enhanced Wall Treatment under Near-Wall Treatment

12.16.19. Stress-Omega Pressure-Strain

To use the Low-Reynold-Number Stress-Omega option described in Low-Re Stress-Omega Model, select Stress-Omega from the Reynolds-Stress Model list in the Viscous Model Dialog Box (p. 1903). (This option will not appear unless you have activated the RSM.) The following options are not available when the Stress-Omega option is enabled:

- Wall BC from k Equation under Reynolds-Stress Options
- Wall Reflection Effects under Reynolds-Stress Options
- Standard Wall Functions under Near-Wall Treatment
- Scalable Wall Functions under Near-Wall Treatment
- Non-Equilibrium Wall Functions under Near-Wall Treatment
- Enhanced Wall Treatment under Near-Wall Treatment

Instead, the following options are available:

- Low-Re Corrections under k-omega Options
- Shear Flow Corrections under k-omega Options
- Scale-Adaptive Simulation (SAS) under Scale-Resolving Simulation Options

12.16.20. Subgrid-Scale Model

If you have selected the Large Eddy Simulation model, you will be able to choose one of the subgrid-scale models described in Subgrid-Scale Models (in the Theory Guide). You can choose from the Smagorinsky-Lilly, WALE, or Kinetic-Energy Transport subgrid-scale models. Note that Dynamic Stress is an option available with the Smagorinsky-Lilly model, while the Kinetic-Energy Transport model is always run as a dynamic model. The Dynamic Fvar option is available for all of the subgrid-scale models when Non-Premixed Combustion or Partially Premixed Combustion is selected in the Species Model Dialog Box (p. 1943).

Important

These options will not appear unless you have activated the LES model.
12.16.21. Customizing the Turbulent Viscosity

If you are using the Spalart-Allmaras, \( k-\epsilon \), \( k-\omega \), DES, or LES models, a UDF can be used to customize the turbulent viscosity. This option will enable you to modify \( \mu_f \) in the case of the Spalart-Allmaras, \( k-\epsilon \), and \( k-\omega \) models, and incorporate completely new subgrid models in the case of the LES model. More information about UDFs can be found in the UDF Manual.

In the Viscous Model Dialog Box (p. 1903), under User-Defined Functions, select the appropriate user-defined function in the Turbulent Viscosity drop-down list. For the LES model, select the appropriate UDF in the Subgrid-Scale Turbulent Viscosity drop-down list.

12.16.22. Customizing the Turbulent Prandtl and Schmidt Numbers

If you are using the standard or realizable \( k-\epsilon \) model or the standard \( k-\omega \) model, a UDF can be used to customize the turbulent Prandtl and Schmidt numbers. This option will allow you to calculate \( \sigma_k \) and either \( \sigma_\epsilon \) or \( \sigma_\omega \) (depending on the choice of either \( k-\epsilon \) or \( k-\omega \) model) by using a UDF. You will also be able to calculate the value of the energy turbulent Prandtl number (\( Pr_f \) in Equation 4.57 in the Theory Guide) and the turbulent Prandtl number at the wall (\( Pr_f \) in Equation 4.294 in the Theory Guide) in this way. More information about UDFs can be found in the UDF Manual.

In the Viscous Model Dialog Box (p. 1903), under User-Defined Functions, select the appropriate UDF from the drop-down lists under Prandtl and Schmidt Numbers. Options include: TKE Prandtl Number, TDR Prandtl Number (\( k-\epsilon \) models only), SDR Prandtl Number (\( k-\omega \) model only), Energy Prandtl Number, Wall Prandtl Number, and Turbulent Schmidt Number.

12.16.23. Modeling Turbulence with Non-Newtonian Fluids

If the turbulent flow involves non-Newtonian fluids, you can use the define/models/viscous/turbulence-expert/turb-non-newtonian? text command to enable the selection of non-Newtonian options for the material viscosity. See Viscosity for Non-Newtonian Fluids (p. 429) for details about these options.

12.16.24. Including Scale-Adaptive Simulation with \( \omega \)-Based URANS Models

You have the option of including Scale-Adaptive Simulation (SAS) with most \( \omega \)-based URANS models. For details about SAS and how to include it, see Scale-Adaptive Simulation (SAS) (p. 703) and Setting Up Scale-Adaptive Simulation (SAS) Modeling (p. 722), respectively.

12.16.25. Including Detached Eddy Simulation with the Transition SST Model

You have the option of including Detached Eddy Simulation (DES) with the Transition SST model. For details about DES and how to include it, see Detached Eddy Simulation (DES) (p. 703) and Setting Up DES with the Transition SST Model (p. 728), respectively.

12.16.26. Shielding Functions for the SST Detached Eddy Simulation Model

The SST shielding (or blending) functions, F1 and F2 (which is more conservative than F1), are defined in Equation 4.102 and Equation 4.104 in the Theory Guide, respectively. In addition, the SST shielding functions DDES (Delayed DES) and IDDES (Improved Delayed DES), are described in DES with the SST \( k-\omega \) Model and Improved Delayed Detached Eddy Simulation (IDDES) in the Theory Guide. DDES is recommended and is used as the default.
12.17. Defining Turbulence Boundary Conditions

For additional information, see the following sections:
12.17.1. The Spalart-Allmaras Model
12.17.2. $k$-$\varepsilon$ Models and $k$-$\omega$ Models
12.17.3. Reynolds Stress Model
12.17.4. Large Eddy Simulation Model

12.17.1. The Spalart-Allmaras Model

When you are modeling turbulent flows in ANSYS Fluent using the Spalart-Allmaras model, you must provide the boundary conditions for $\tilde{\nu}$ in addition to other mean solution variables. The boundary conditions for $\tilde{\nu}$ at the walls are internally taken care of by ANSYS Fluent, which obviates the need for your inputs. The boundary condition input for $\tilde{\nu}$, which you must enter in ANSYS Fluent, is the one at inlet boundaries (velocity inlet, pressure inlet, etc.). In many situations, it is important to specify correct or realistic boundary conditions at the inlets, because the inlet turbulence can significantly affect the downstream flow.

You may want to include the effects of the wall roughness on selected wall boundaries. In such cases, you can specify the roughness parameters (roughness height and roughness constant) in the dialog boxes of the corresponding wall boundaries (see Setting the Roughness Parameters (p. 317)).

12.17.2. $k$-$\varepsilon$ Models and $k$-$\omega$ Models

When you are modeling turbulent flows in ANSYS Fluent using one of the $k$-$\varepsilon$ models or one of the $k$-$\omega$ models, you must provide the boundary conditions for $k$ and $\varepsilon$ (or $k$ and $\omega$) in addition to other mean solution variables. The boundary conditions for $k$ and $\varepsilon$ (or $k$ and $\omega$) at the walls are internally taken care of by ANSYS Fluent, which obviates the need for your inputs. The boundary condition inputs for $k$ and $\varepsilon$ (or $k$ and $\omega$), which you must enter in ANSYS Fluent, are the ones at inlet boundaries (velocity inlet, pressure inlet, etc.). In many situations, it is important to specify correct or realistic boundary conditions at the inlets, because the inlet turbulence can significantly affect the downstream flow.

See Determining Turbulence Parameters (p. 257) for details about specifying the boundary conditions for $k$ and $\varepsilon$ (or $k$ and $\omega$) at the inlets.

You may want to include the effects of the wall roughness on selected wall boundaries. In such cases, you can specify the roughness parameters (roughness height and roughness constant) in the dialog boxes for the corresponding wall boundaries (see Setting the Roughness Parameters (p. 317)).

---

**Note**

If you have selected the **Enhanced Wall Treatment** option as the **Near-Wall Treatment**, then the **Wall Roughness** parameters will not be accessible.

Additionally, you can control whether or not to set the turbulent viscosity to zero within a laminar zone. If the fluid zone in question is laminar, the text command `define/boundary-conditions/fluid` will contain an option called `Set Turbulent Viscosity to zero within laminar zone?`. By setting this option to `yes`, ANSYS Fluent will set both the production term in the turbulence transport equation and $\mu_t$ to zero. In contrast, when the **Laminar Zone** option is enabled in a **Fluid** cell zone.
condition dialog box, only the production term is set to zero. See Specifying a Laminar Zone (p. 217) for details about laminar zones.

**Important**

Note that the laminar zone feature is also available for the Spalart-Allmaras and RSM models.

### 12.17.3. Reynolds Stress Model

The specification of turbulent boundary conditions for the RSM is the same as for the other turbulence models for all boundaries except at boundaries where flow enters the domain. Additional input methods are available for these boundaries and are described here.

When you choose to use the RSM, the default inlet boundary condition inputs required are identical to those required when the \( k-\varepsilon \) model is active. You can input the turbulence quantities using any of the turbulence specification methods described in Determining Turbulence Parameters (p. 257). ANSYS Fluent then uses the specified turbulence quantities to derive the Reynolds stresses at the inlet from the assumption of isotropy of turbulence:

\[
\bar{u}_{i}^{2} = \frac{2}{3}k \quad (i = 1, 2, 3) \tag{12.6}
\]

\[
\bar{u}_{i}\bar{u}_{j} = 0.0 \tag{12.7}
\]

where \( \bar{u}_{i}^{2} \) is the normal Reynolds stress component in each direction. The boundary condition for \( \varepsilon \) is determined in the same manner as for the \( k-\varepsilon \) turbulence models (see Determining Turbulence Parameters (p. 257)). To use this method, you will select **K or Turbulent Intensity** as the **Reynolds-Stress Specification Method** in the appropriate boundary condition dialog box.

Alternately, you can directly specify the Reynolds stresses by selecting the **Reynolds-Stress Components** as the **Reynolds-Stress Specification Method** in the boundary condition dialog box. When this option is selected, you should input the Reynolds stresses directly.

You can set the Reynolds stresses by using constant values, profile functions of coordinates (see Profiles (p. 377)), or user-defined functions (in the UDF Manual).
It is possible to specify the magnitude of random fluctuations of the velocity components at an inlet only if the velocity inlet boundary condition is selected. In this case, you must specify a **Turbulence Intensity** that determines the magnitude of the random perturbations on individual mean velocity components as described in *Inlet Boundary Conditions for the LES Model* (in the Theory Guide). For all boundary types other than velocity inlets, the boundary conditions for LES remain the same as for laminar flows.
12.18. Providing an Initial Guess for $k$ and $\varepsilon$ (or $k$ and $\omega$)

For flows using one of the $k-\varepsilon$ models, one of the $k-\omega$ models, or the RSM, the converged solutions or (for unsteady calculations) the solutions after a sufficiently long time has elapsed should be independent of the initial values for $k$ and $\varepsilon$ (or $k$ and $\omega$). For better convergence, however, it is beneficial to use a reasonable initial guess for $k$ and $\varepsilon$ (or $k$ and $\omega$).

In general, it is recommended that you start from a fully-developed state of turbulence. When you use the enhanced wall treatment for the $k-\varepsilon$ models or the RSM, it is critically important to specify fully-developed turbulence fields. Guidelines are provided below.

- If you were able to specify reasonable boundary conditions at the inlet, it may be a good idea to compute the initial values for $k$ and $\varepsilon$ (or $k$ and $\omega$) in the whole domain from these boundary values. (See Initializing the Solution (p. 1445) for details.)

- For more complex flows (for example, flows with multiple inlets with different conditions) it may be better to specify the initial values in terms of turbulence intensity. 5–10% is enough to represent fully-developed turbulence. The values of $k$ can then be computed from the turbulence intensity and the characteristic mean velocity magnitude of your problem ($k = 1.5 \left( \mu_{avg} \right)^2$).

You should specify an initial guess for $\varepsilon$ so that the resulting eddy viscosity ($C_\mu \frac{k^2}{\varepsilon}$) is sufficiently large in comparison to the molecular viscosity. In fully-developed turbulence, the turbulent viscosity is roughly two orders of magnitude larger than the molecular viscosity. From this, you can compute $\varepsilon$.

$$\varepsilon = C_\mu \frac{k^2}{\mu_T} = \frac{k^2}{\mu_T} \mu$$

(12.8)

where $\mu_T$ is the turbulent viscosity ratio which can be prescribed at the inlet and then used for the domain initialization.

Note that, for the RSM, Reynolds stresses are initialized automatically using Equation 12.6 (p. 742) and Equation 12.7 (p. 742).

Compared to laminar flows, simulations of turbulent flows are more challenging in many ways. For the Reynolds-averaged approach, additional equations are solved for the turbulence quantities. Since the equations for mean quantities and the turbulent quantities ($\mu_T$, $k$, $\varepsilon$, $\omega$, or the Reynolds stresses) are strongly coupled in a highly non-linear fashion, it takes more computational effort to obtain a converged turbulent solution than to obtain a converged laminar solution. The LES model, while embodying a simpler, algebraic model for the subgrid-scale viscosity, requires a transient solution on a very fine mesh.

The fidelity of the results for turbulent flows is largely determined by the turbulence model being used. Here are some guidelines that can enhance the quality of your turbulent flow simulations.

For additional information, see the following sections:
   12.19.1. Mesh Generation
   12.19.2. Accuracy
12.19.1. Mesh Generation

The following are suggestions to follow when generating the mesh for use in your turbulent flow simulation:

- First imagine the flow under consideration, then identify the main flow features expected in the flow using your physical intuition or any data for a similar flow situation. Generate a mesh that can resolve the major features that you expect.

- If the flow is wall-bounded, and the wall is expected to affect the flow significantly, then take additional care when generating the mesh. You should avoid using a mesh that is too fine (for the wall-function approach) or too coarse (for the enhanced wall treatment approach). See Grid Resolution for RANS Models (p. 701) and Wall Boundary Layers (p. 705) for details.

12.19.2. Accuracy

The suggestions below are provided to help you obtain better accuracy in your results:

- Use the turbulence model that is better suited for the salient features you expect to see in the flow (see Choosing a Turbulence Model (p. 697)).

- Because the mean quantities have larger gradients in turbulent flows than in laminar flows, it is recommended that you use high-order schemes for the convection terms. This is especially true if you employ a triangular or tetrahedral mesh. Note that excessive numerical diffusion adversely affects the solution accuracy, even with the most elaborate turbulence model.

- In some flow situations involving inlet boundaries, the flow downstream of the inlet is dictated by the boundary conditions at the inlet. In such cases, you should exercise care to make sure that reasonably realistic boundary values are specified.

12.19.3. Convergence

The suggestions below are provided to help you enhance convergence for turbulent flow calculations:

- Starting with excessively crude initial guesses for mean and turbulence quantities may cause the solution to diverge. A safe approach is to start your calculation using conservative (small) under-relaxation parameters and (for the density-based solvers) a conservative Courant number, and increase them gradually as the iterations proceed and the solution begins to settle down.

- It is also helpful for faster convergence to start with reasonable initial guesses for the $k$ and $\varepsilon$ (or $k_e$ and $\omega$) fields. Particularly when the enhanced wall treatment is used, it is important to start with a sufficiently developed turbulence field, as recommended in Providing an Initial Guess for $k$ and $\varepsilon$ (or $k$ and $\omega$) (p. 744), to avoid the need for an excessive number of iterations to develop the turbulence field.

- When you are using the RNG $k-e$ model, an approach that might help you achieve better convergence is to obtain a solution with the standard $k-e$ model before switching to the RNG model. Due to the additional non-linearities in the RNG model, lower under-relaxation factors and (for the density-based solvers) a lower Courant number might also be necessary.
Note that when you use the enhanced wall treatment, you may sometimes find during the calculation that the residual for $\varepsilon$ is reported to be zero. This happens when your flow is such that $Re_y$ is less than 200 in the entire flow domain, and $\varepsilon$ is obtained from the algebraic formula (Equation 4.315 in the Theory Guide) instead of from its transport equation.

### 12.19.4. RSM-Specific Solution Strategies

Using the RSM creates a high degree of coupling between the momentum equations and the turbulent stresses in the flow, and therefore the calculation can be more prone to stability and convergence difficulties than with the $k$-$\varepsilon$ models. When you use the RSM, therefore, you may need to adopt special solution strategies in order to obtain a converged solution. The following strategies are generally recommended:

- Begin the calculations using the standard $k$-$\varepsilon$ model. Turn on the RSM and use the $k$-$\varepsilon$ solution data as a starting point for the RSM calculation.

- Use low under-relaxation factors (0.2 to 0.3) and (for the density-based solvers) a low Courant number for highly swirling flows or highly complex flows. In these cases, you may need to reduce the under-relaxation factors both for the velocities and for all of the stresses.

Instructions for setting these solution parameters are provided below. If you are applying the RSM to prediction of a highly swirling flow, you will want to consider the solution strategies discussed in Swirling and Rotating Flows (p. 519) as well.

#### 12.19.4.1. Under-Relaxation of the Reynolds Stresses

ANSYS Fluent applies under-relaxation to the Reynolds stresses. You can set under-relaxation factors using the Solution Controls Task Page (p. 2208).

**Solution Controls**

The default settings of 0.5 are recommended for most cases. You may be able to increase these settings and speed up the convergence when the RSM solution begins to converge.

In some situations, when poor convergence is observed one might facilitate the convergence rates by modifying some of the under-relaxation values whilst leaving the others unchanged. This might be a more successful approach than the simple scaling of all under-relaxation values.

#### 12.19.4.2. Disabling Calculation Updates of the Reynolds Stresses

In some instances, you may want to let the current Reynolds stress field remain fixed, skipping the solution of the Reynolds transport equations while solving the other transport equations. You can activate/deactivate all Reynolds stress equations in the Equations dialog box, accessed from the Solution Controls Task Page (p. 2208).

**Solution Controls → Equations...**

#### 12.19.4.3. Residual Reporting for the RSM

When you use the RSM for turbulence, ANSYS Fluent reports the equation residuals for the individual Reynolds stress transport equations. You can apply the usual convergence criteria to the Reynolds stress...
residuals; normalized residuals in the range of $10^{-3}$ usually indicate a practically-converged solution. However, you may need to apply tighter convergence criteria (below $10^{-4}$) to ensure full convergence.

### 12.19.5. LES-Specific Solution Strategies

Large eddy simulation involves running a transient solution from some initial condition, on an appropriately fine mesh, using an appropriate time step size. The solution must be run long enough to become independent of the initial condition and to enable the statistics of the flow field to be determined.

The following are suggestions to follow when running a large eddy simulation:

1. Start by running a steady state flow simulation using a Reynolds-averaged turbulence model such as standard $k-\varepsilon$, $k-\omega$, or even RSM. Run until the flow field is reasonably converged and then use the `solve/initialize/init-instantaneous-vel` text command to generate the instantaneous velocity field out of the steady-state RANS results. This command must be executed before LES is enabled. This option is available for all RANS-based models and it will create a much more realistic initial field for the LES run. Additionally, it will help in reducing the time needed for the LES simulation to reach a statistically stable mode. This step is optional.

2. When you enable LES, ANSYS Fluent will automatically turn on the unsteady solver option and choose the second-order implicit formulation. You will need to set the appropriate time step size and all the needed solution parameters. (See User Inputs for Time-Dependent Problems (p. 1463) for guidelines on setting solution parameters for transient calculations in general.) The bounded central differencing spatial discretization scheme will be automatically enabled for momentum equations. Both the bounded central-differencing and pure central-differencing schemes are available for all equations when running LES simulations.

3. Run LES until the flow becomes statistically steady. The best way to see if the flow is fully developed and statistically steady is to monitor forces and solution variables (for example, velocity components or pressure) at selected locations in the flow.

4. Zero out the initial statistics using the `solve/initialize/init-flow-statistics` text command. Before you restart the solution, enable Data Sampling for Time Statistics in the Run Calculation Task Page (p. 2269), as described in User Inputs for Time-Dependent Problems (p. 1463). With this option enabled, ANSYS Fluent will gather data for time statistics while performing a large eddy simulation. You can set the Sampling Interval such that Data Sampling for Time Statistics can be performed at the specified frequency. When Data Sampling for Time Statistics is enabled, the statistics collected at each sampling interval can be postprocessed and you can then view both the mean and the root-mean-square (RMS) values in ANSYS Fluent. The Time Sampled displays the time period over which data has been sampled for the postprocessing of the mean and RMS values. As long as the time step size has been constant, dividing this by the time step size yields the number of data sets that have been collected. If the time step size is varied, every contribution of data sets sampled is automatically weighted by the current time step size.

5. Continue until you get statistically stable data. The duration of the simulation can be determined beforehand by estimating the mean flow residence time in the solution domain ($L/\bar{U}$, where $L$ is the characteristic length of the solution domain and $\bar{U}$ is a characteristic mean flow velocity). The simulation should be run for at least a few mean flow residence times.

Instructions for setting the solution parameters for LES are provided below.
12.19.5.1. Temporal Discretization

ANSYS Fluent provides both first-order and second-order temporal discretizations. For LES, the second-order discretization is recommended.

Solution Methods

12.19.5.2. Spatial Discretization

Overly diffusive schemes such as the first-order upwind or power law scheme should be avoided, because they may unduly damp out the energy of the resolved eddies. The central-differencing based schemes are recommended for all equations when you use the LES model. ANSYS Fluent provides two central-differencing based schemes: pure central-differencing and bounded central-differencing. The bounded scheme is the default option when you select LES or DES.

Solution Methods

12.20. Postprocessing for Turbulent Flows

ANSYS Fluent provides postprocessing options for displaying, plotting, and reporting various turbulence quantities, which include the main solution variables and other auxiliary quantities.

Turbulence quantities that can be reported for the Spalart-Allmaras model are as follows:

- Modified Turbulent Viscosity
- Turbulent Viscosity
- Effective Viscosity
- Turbulent Viscosity Ratio
- Effective Thermal Conductivity
- Effective Prandtl Number
- Wall Yplus
- Curvature Correction Function $fr$ (only when the curvature correction is enabled)

Turbulence quantities that can be reported for the $k$-$\varepsilon$ models are as follows:

- Turbulent Kinetic Energy ($k$)
- Turbulent Intensity
- Turbulent Dissipation Rate (Epsilon)
- Production of $k$
- Turbulent Viscosity
- Effective Viscosity
Postprocessing for Turbulent Flows

- Turbulent Viscosity Ratio
- Effective Thermal Conductivity
- Effective Prandtl Number
- Wall Ystar
- Wall Yplus
- Turbulent Reynolds Number (Re_y) (only when the enhanced wall treatment is used for the near-wall treatment)
- Curvature Correction Function fr (only when the curvature correction is enabled)

Turbulence quantities that can be reported for the $k-\omega$ models are as follows:
- Turbulent Kinetic Energy (k)
- Turbulent Intensity
- Turbulent Dissipation Rate (Epsilon)
- Intermittency
- Specific Dissipation Rate (Omega)
- Production of k
- Turbulent Viscosity
- Effective Viscosity
- Turbulent Viscosity Ratio
- Effective Thermal Conductivity
- Effective Prandtl Number
- Wall Ystar
- Wall Yplus
- Turbulent Reynolds Number (Re_y)
- Curvature Correction Function fr (only when the curvature correction is enabled)

Turbulence quantities that can be reported for the Standard $k-\omega$ model in combination with the SAS model are as follows:
- all of the quantities available for the $k-\omega$ model
- Normalized Q criterion
- Q criterion
Turbulence quantities that can be reported for the transition $k-kl-\omega$ model are as follows:

- Turbulent Kinetic Energy ($k$)
- Laminar Kinetic Energy
- Total Fluctuation Energy
- Turbulent Intensity
- Turbulent Dissipation Rate (Epsilon)
- Specific Dissipation Rate (Omega)
- Production of $k$
- Production of laminar $k$
- Turbulent Viscosity
- Turbulent Viscosity (large-scale)
- Turbulent Viscosity (small-scale)
- Effective Viscosity
- Turbulent Viscosity Ratio
- Effective Thermal Conductivity
- Effective Prandtl Number
- Wall Ystar
- Wall Yplus
- Turbulent Reynolds Number (Re_y)

Turbulence quantities that can be reported for the Transition SST model are as follows:

- Turbulent Kinetic Energy ($k$)
- Turbulent Intensity
- Turbulent Dissipation Rate (Epsilon)
- Intermittency
- Intermittency Effective
- Momentum Thickness Re
- Geometric Roughness Height
- Specific Dissipation Rate (Omega)
- Production of $k$
• Turbulent Viscosity
• Effective Viscosity
• Turbulent Viscosity Ratio
• Effective Thermal Conductivity
• Effective Prandtl Number
• Wall Ystar
• Wall Yplus
• Turbulent Reynolds Number (Re_y)
• Curvature Correction Function fr (only when the curvature correction is enabled)

Turbulence quantities that can be reported for the Transition SST model in combination with the SAS model are as follows:
• all of the quantities available for the Transition SST model
• Normalized Q criterion
• Q criterion

Turbulence quantities that can be reported for the Transition SST model in combination with the DES model are as follows:
• all of the quantities available for the Transition SST model
• DES TKE Dissipation Multiplier
• Normalized Q criterion
• Q criterion

**Note**

For the Transition SST model in combination with the DES model, **DES TKE Dissipation Multiplier** represents the function $F_{DES}$ in Equation 4.249 and $F_{IDDES}$ in Equation 4.250 depending on the specified model. Within the DES concept, the **DES TKE Dissipation Multiplier** increases the destruction term in the transport equation for the turbulence kinetic energy in LES regions ($F_{DES} > 1$). This increase in destruction terms reduces the eddy viscosity in LES regions.

Turbulence quantities that can be reported for the RSM are as follows:
• Turbulent Kinetic Energy (k)
• Turbulent Intensity
• UU Reynolds Stress
Modeling Turbulence

- VV Reynolds Stress
- WW Reynolds Stress
- UV Reynolds Stress
- VW Reynolds Stress
- UW Reynolds Stress
- Turbulent Dissipation Rate (Epsilon)
- Specific Dissipation Rate (Omega)
- Production of k
- Turbulent Viscosity
- Effective Viscosity
- Turbulent Viscosity Ratio
- Effective Thermal Conductivity
- Effective Prandtl Number
- Wall Ystar
- Wall Yplus
- Turbulent Reynolds Number (Re_y)

Turbulence quantities that can be reported for the $\omega$-based RSM in combination with the SAS model are as follows:

- all of the quantities available for the RSM model except for Turbulent Reynolds Number (Re_y)
- Normalized Q criterion
- Q criterion

Turbulence quantities that can be reported for the SAS model in combination with the SST $k-\omega$ model are as follows:

- Turbulent Kinetic Energy (k)
- Turbulent Intensity
- Turbulent Dissipation Rate (Epsilon)
- Intermittency
- Specific Dissipation Rate (Omega)
- Production of k
- Turbulent Viscosity
• Effective Viscosity
• Turbulent Viscosity Ratio
• Effective Thermal Conductivity
• Effective Prandtl Number
• Wall Yplus
• Wall Ystar
• Curvature Correction Function $fr$ (only when the curvature correction is enabled)
• Normalized Q criterion
• Q criterion

Turbulence quantities that can be reported for the DES model are as follows:

• Intermittency
• Modified Turbulent Viscosity
• Turbulent Viscosity
• Effective Viscosity
• Turbulent Viscosity Ratio
• Effective Thermal Conductivity
• Effective Prandtl Number
• Wall Yplus
• DES TKE Dissipation Multiplier
• Curvature Correction Function $fr$ (only when the curvature correction is enabled)
• Normalized Q criterion
• Q criterion

---

**Note**

For the SST $k-\omega$ based DES models, **DES TKE Dissipation Multiplier** represents the function $F_{DES}$ in Equation 4.249 and $F_{fIDDES}$ in Equation 4.250 depending on the specified model. Within the DES concept, the **DES TKE Dissipation Multiplier** increases the destruction term in the transport equation for the turbulence kinetic energy in LES regions ($F_{DES} > 1$). This increase in destruction terms reduces the eddy viscosity in LES regions.

For the Spalart-Allmaras and Realizable $k-\epsilon$ based DES models, the **DES TKE Dissipation Multiplier** represents the function $f_d$ in Equation 4.237 and Equation 4.244 respectively.
Turbulence quantities that can be reported for the LES model are as follows:

- **Turbulence Kinetic Energy**
- **Turbulence Intensity**
- **Subgrid Kinetic Energy**
- **Production of k**
- **Subgrid Turbulent Viscosity**
- **Subgrid Effective Viscosity**
- **Subgrid Turbulent Viscosity Ratio**
- **Subgrid Filter Length**
- **Subgrid Test-Filter Length**
- **Subgrid Dissipation Rate**
- **Subgrid Dynamic Viscosity Const**
- **Subgrid Dynamic Prandtl Number**
- **Subgrid Dynamic Sc of Species**
- **Subtest Kinetic Energy**
- **Effective Thermal Conductivity**
- **Effective Prandtl Number**
- **Wall Ystar**
- **Wall Yplus**
- **Normalized Q criterion**
- **Q criterion**

Additional turbulence quantities can be reported for the Embedded LES (ELES) model.

---

**Note**

Within the Embedded LES zone, the modeled eddy viscosity is determined by an algebraic sub-grid scale eddy viscosity model. The global turbulence model is either frozen or, if it is either SAS or DES with an underlying two-equation RANS model, runs in a "passive mode", that is without affecting the momentum equations.

Hence, most turbulence postprocessing in the Embedded LES zone refers to the frozen or "passive" global turbulence model. Special care is necessary with the modeled eddy viscosity, because there are two to consider: one from the frozen / passive global turbulence model;
and one from the "local" algebraic sub-grid scale model that is running within the Embedded LES zone and actually affects the momentum equations.

- Some postprocessing quantities refer to a "passive" global turbulence model or are zero if the global model cannot run in "passive" mode and therefore is frozen in the Embedded LES zone.
  - **Turbulent Viscosity**
  - **Turbulent Viscosity Ratio**

- In the Embedded LES zone, the sub-grid scale eddy viscosity from the local algebraic model, which actually affects the momentum equations, is displayed as:
  - **LES Subgrid Turbulent Viscosity**

- The following quantities are specific to the Dynamic LES sub-grid scale eddy viscosity models. They are available in Embedded LES zones if the Dynamic Smagorinsky model is used in any Embedded LES zone; they are also available for global LES with the Dynamic Smagorinsky or the Dynamic TKE Transport sub-grid scale model:
  - **Subgrid Test-Filter Length**
  - **Subgrid Dynamic Viscosity Const**
  - **Subtest Kinetic Energy**

All of these variables can be found in the **Turbulence...** category of the variable selection drop-down list that appears in postprocessing dialog boxes. See *Field Function Definitions* (p. 1765) for their definitions.

For additional information, see the following sections:
- 12.20.1. Custom Field Functions for Turbulence
- 12.20.2. Postprocessing Turbulent Flow Statistics
- 12.20.3. Troubleshooting

**12.20.1. Custom Field Functions for Turbulence**

In addition to the quantities listed in *Postprocessing for Turbulent Flows* (p. 748), above, you can define your own turbulence quantities using the **Custom Field Function Calculator Dialog Box** (p. 2448).

**Define** → **Custom Field Functions...**

The following functions may be useful:

- the ratio of production of $k$ to its dissipation ($G_k / \rho \varepsilon$)
- the ratio of the mean flow to turbulent time scale, $\eta$ ($\equiv S_k / \varepsilon$)
- the Reynolds stresses derived from the Boussinesq formula (for example, $- \overline{u'v'} = \nu \frac{\partial \overline{u}}{\partial y}$)
12.20.2. Postprocessing Turbulent Flow Statistics

As described in Large Eddy Simulation (LES) Model (in the Theory Guide), LES involves the solution of a transient flow field, but it is the mean flow quantities that are of interest from an engineering standpoint.

For all other turbulent flow, if Data Sampling for Time Statistics is enabled in the Run Calculation Task Page (p. 2269), ANSYS Fluent gathers data for time statistics while performing the simulation. The statistics that ANSYS Fluent collects at each sampling interval (which consists of the mean and the root-mean-square (RMS) values) can be postprocessed by selecting Unsteady Statistics... in any of the postprocessing dialog boxes. You can view several variables that include, but are not limited to, shear stresses (Resolved UV/UW/VW Reynolds Stress), flow heat fluxes (Resolved UT/VT/WT Heat Flux), and species statistics (RMS Mass Fraction of species and Mean Mass Fraction of species). If you select Unsteady Wall Statistics... in any of the postprocessing dialog boxes, you can view wall statistics such as Mean Pressure Coefficient, Mean Wall Shear Stress, Mean X-Wall Shear Stress, Mean Y-Wall Shear Stress, Mean Z-Wall Shear Stress, Mean Skin Friction Coefficient, Mean Surface Heat Flux, Mean Surface Heat Transfer Coef., Mean Surface Nusselt Number, Mean Surface Stanton Number. Note that these quantities are only the statistical evaluation of sampled solution data, and do not contain any kind of modeled turbulent fluctuations. See Postprocessing for Time-Dependent Problems (p. 1476) for details.

The Time Sampled displays the time period over which data has been sampled for the postprocessing of the mean and RMS values. As long as the time step size has been constant, dividing this by the time step size yields the number of data sets that have been collected. If the time step size is varied, every contribution of data sets sampled is automatically weighted by the current time step size.

---

**Important**

Note that mean statistics are collected only in interior cells and not on wall surfaces. Therefore, when node or cell values of mean quantities are plotted on the wall surface, you are actually plotting values in nearby cells attached to the wall.

There may be cases when you want to control what set of variables are available for postprocessing. To enable or disable certain variables, go to

**Run Calculation → Sampling Options...**

The Sampling Options dialog box will open, where you can enable or disable the statistics shown in Figure 12.22: Sampling Options Dialog Box (p. 757).
Figure 12.22: Sampling Options Dialog Box

Important

When including or excluding statistics on variables, it is recommended that you re-initialize the flow statistics.

12.20.3. Troubleshooting

You can use the postprocessing options not only for the purpose of interpreting your results but also for investigating any anomalies that may appear in the solution. For instance, you may want to plot contours of the $k$ field to check if there are any regions where $k$ is erroneously large or small. You should see a high $k$ region in the region where the production of $k$ is large. You may want to display the turbulent viscosity ratio field in order to see whether or not the turbulence takes full effect. Usually the turbulent viscosity is at least two orders of magnitude larger than molecular viscosity for fully-developed turbulent flows modeled using the RANS approach (that is, not using LES). You may also want to see whether you are using an adequate near-wall mesh for the enhanced wall treatment. To ensure this, you can display filled contours of $Re_y$ (turbulent Reynolds number) overlaid on the mesh.
13.1. Introduction

The flow of thermal energy from matter occupying one region in space to matter occupying a different region in space is known as heat transfer. Heat transfer can occur by three main mechanisms: conduction, convection, and radiation. Physical models involving conduction and/or convection only are the simplest (Modeling Conductive and Convective Heat Transfer (p. 759)), while buoyancy-driven flow or natural convection (Natural Convection and Buoyancy-Driven Flows (p. 765)), and flow involving radiation (Modeling Radiation (p. 777)) are more complex. Depending on your problem, ANSYS Fluent will solve a variation of the energy equation that takes into account the heat transfer methods you have specified. ANSYS Fluent is also able to predict heat transfer in periodically repeating geometries (Modeling Periodic Heat Transfer (p. 840)), therefore greatly reducing the required computational effort in certain cases.

13.2. Modeling Conductive and Convective Heat Transfer

ANSYS Fluent allows you to include heat transfer within the fluid and/or solid regions in your model. Problems ranging from thermal mixing within a fluid to conduction in composite solids can therefore be handled by ANSYS Fluent.

When your ANSYS Fluent model includes heat transfer you will need to activate the relevant physical models, supply thermal boundary conditions, and input material properties (which may vary with temperature) that govern heat transfer. For information about heat transfer theory, see Heat Transfer Theory in the Theory Guide. Information about heat transfer theory and how to set up and use heat transfer in your ANSYS Fluent model is presented in the following subsections:

13.2.1. Solving Heat Transfer Problems
13.2.2. Solution Strategies for Heat Transfer Modeling
13.2.3. Postprocessing Heat Transfer Quantities
13.2.4. Natural Convection and Buoyancy-Driven Flows
13.2.5. Shell Conduction Considerations

13.2.1. Solving Heat Transfer Problems

The procedure for setting up a heat transfer problem is described below. Note that this procedure includes only those steps necessary for the heat transfer model itself; you will need to set up other models, boundary conditions, etc. as usual.

1. To activate the calculation of heat transfer, enable the Energy Equation option in the Energy dialog box (Figure 13.1: The Energy Dialog Box (p. 760)).
2. (Optional, pressure-based solver only.) If you are modeling viscous flow and you want to include the viscous heating terms in the energy equation, enable the Viscous Heating option in the Viscous Model dialog box.

As noted in Inclusion of the Viscous Dissipation Terms in the Theory Guide, the viscous heating terms in the energy equation are (by default) ignored by ANSYS Fluent when the pressure-based solver is used. They are always included for the density-based solver. Viscous dissipation should be enabled when the shear stress in the fluid is large (for example, in lubrication problems) and/or in high-velocity, compressible flows. See Equation 5.9 in the Theory Guide.

3. Define thermal boundary conditions at flow inlets, flow outlets, and walls.

Boundary Conditions

At flow inlets and exits you will set the temperature; at walls you may use any of the following thermal conditions:

- specified heat flux
- specified temperature
- convective heat transfer
- external radiation
- combined external radiation and external convective heat transfer

Thermal Boundary Conditions at Walls (p. 318) provides details on the model inputs that govern these thermal boundary conditions. The default thermal boundary condition at inlets is a specified temperature of 300 K; at walls the default condition is zero heat flux (adiabatic). See Cell Zone and Boundary Conditions (p. 201) for details about boundary condition inputs.

---

Important

If your heat transfer application involves two separated fluid regions, see the information provided below.
4. Define material properties for heat transfer.

**Materials**

Heat capacity and thermal conductivity must be defined, and you can specify many properties as functions of temperature as described in Physical Properties (p. 397).

### 13.2.1.1. Limiting the Predicted Temperature Range

For stability reasons, ANSYS Fluent includes a limit on the predicted temperature range. The purpose of the temperature ceiling and floor is to improve the stability of calculations in which the temperature should physically lie within known limits. Sometimes intermediate solutions of the equations give rise to temperatures beyond these limits for which property definitions, etc. are not well defined.

The temperature limits keep the temperatures within the expected range for your problem. If the ANSYS Fluent calculation predicts a temperature above the maximum limit, the stored temperature values are “pegged” at this maximum value. The default for the temperature ceiling is 5000 K. If the ANSYS Fluent calculation predicts a temperature below the minimum limit, the stored temperature values are "pegged" at this minimum value. The default for the temperature minimum is 1 K.

If you expect the temperature in your domain to exceed 5000 K, use the **Solution Limits** dialog box to increase the Maximum Temperature.

**Solution Controls → Limits...**

### 13.2.1.2. Modeling Heat Transfer in Two Separated Fluid Regions

If your heat transfer application involves two fluid regions separated by a solid zone or a wall, as illustrated in Figure 13.2: Typical Counterflow Heat Exchanger Involving Heat Transfer Between Two Separated Fluid Streams (p. 761), you will need to define the problem with some care. Specifically:

- You should not use outflow boundary conditions in either fluid.
- You can establish separate fluid properties by selecting a different fluid material for each zone. For species calculations, however, you can only select a single mixture material for the entire domain.

**Figure 13.2: Typical Counterflow Heat Exchanger Involving Heat Transfer Between Two Separated Fluid Streams**

---

### 13.2.2. Solution Strategies for Heat Transfer Modeling

Although many simple heat transfer problems can be successfully solved using the default solution parameters assumed by ANSYS Fluent, you may accelerate the convergence of your problem and/or improve the stability of the solution process using some of the guidelines provided in this section.
13.2.2.1. Under-Relaxation of the Energy Equation

When you use the pressure-based solver, ANSYS Fluent under-relaxes the energy equation using the under-relaxation parameter defined by you in the Solution Controls task page, as described in Setting Under-Relaxation Factors (p. 1418).

Solution Controls

If you are using the non-adiabatic non-premixed combustion model, you will set the energy under-relaxation factor as usual but you will also set an under-relaxation factor for temperature, as described below.

ANSYS Fluent uses a default under-relaxation factor of 1.0 for the energy equation, regardless of the form in which it is solved (temperature or enthalpy). In problems where the energy field impacts the fluid flow (via temperature-dependent properties or buoyancy) you should use a lower value for the under-relaxation factor, in the range of 0.8–1.0. In problems where the flow field is decoupled from the temperature field (no temperature-dependent properties or buoyancy forces), you can usually retain the default value of 1.0.

13.2.2.2. Under-Relaxation of Temperature When the Enthalpy Equation is Solved

When the enthalpy form of the energy equation is solved (that is, when you are using the non-adiabatic non-premixed combustion model), ANSYS Fluent also under-relaxes the temperature, updating the temperature by only a fraction of the change that would result from the change in the (under-relaxed) enthalpy values. This second level of under-relaxation can be used to good advantage when you would like to let the enthalpy field change rapidly, but the temperature response (and its effect on fluid properties) to lag. ANSYS Fluent uses a default setting of 1.0 for the under-relaxation on temperature and you can modify this setting using the Solution Controls task page.

13.2.2.3. Disabling the Species Diffusion Term

If you are solving for species transport using the pressure-based solver and you encounter convergence difficulties, you may want to consider disabling the Diffusion Energy Source option in the Species Model dialog box.

Models → Species → Edit...

When this option is disabled, ANSYS Fluent will neglect the effects of species diffusion on the energy equation.

Note that species diffusion effects are always included when the density-based solver is used.

13.2.2.4. Step-by-Step Solutions

Often the most efficient strategy for predicting heat transfer is to compute an isothermal flow first and then add the calculation of the energy equation. The procedure differs slightly, depending on whether or not the flow and heat transfer are coupled.
13.2.2.4.1. Decoupled Flow and Heat Transfer Calculations

If your flow and heat transfer are decoupled (no temperature-dependent properties or buoyancy forces), you can first solve the isothermal flow (energy equation turned off) to yield a converged flow-field solution and then solve the energy transport equation alone.

**Important**

Since the density-based solver always solves the flow and energy equations together, the procedure for solving for energy alone applies to the pressure-based solver, only.

You can temporarily disable the flow equations or the energy equation by deselecting them in the **Equations** dialog box:

You can also disable the energy equation in the **Energy** dialog box:

13.2.2.4.2. Coupled Flow and Heat Transfer Calculations

If the flow and heat transfer are coupled (that is, your model includes temperature-dependent properties or buoyancy forces), you can first solve the flow equations before enabling energy. Once you have a converged flow-field solution, you can enable energy and solve the flow and energy equations simultaneously to complete the heat transfer simulation.

13.2.3. Postprocessing Heat Transfer Quantities

For information about postprocessing heat transfer quantities, see the following sections:

13.2.3.1. Available Variables for Postprocessing
13.2.3.2. Definition of Enthalpy and Energy in Reports and Displays
13.2.3.3. Reporting Heat Transfer Through Boundaries
13.2.3.4. Reporting Heat Transfer Through a Surface
13.2.3.5. Reporting Averaged Heat Transfer Coefficients
13.2.3.6. Exporting Heat Flux Data

13.2.3.1. Available Variables for Postprocessing

ANSYS Fluent provides reporting options for simulations involving heat transfer. You can generate graphical plots or reports of the following variables/functions:

- Static Temperature
- Total Temperature
- Enthalpy
- Relative Total Temperature
- Rothalpy
13.2.3.2. Definition of Enthalpy and Energy in Reports and Displays

The definitions of the reported values of enthalpy and energy will be different depending on whether the flow is compressible or incompressible.

13.2.3.3. Reporting Heat Transfer Through Boundaries

You can use the Flux Reports dialog box to compute the heat transfer through each boundary of the domain, or to sum the heat transfer through all boundaries to check the heat balance.

![Reports → Fluxes → Set Up...](image)

It is recommended that you perform a heat balance check to ensure that your solution is truly converged.

13.2.3.4. Reporting Heat Transfer Through a Surface

You can use the Surface Integrals dialog box to compute the heat transfer through any boundary or any surface created using the methods described in Creating Surfaces for Displaying and Reporting Data (p. 1579).

![Reports → Surface Integrals → Set Up...](image)

To report the mass flow rate of enthalpy

\[ Q = \int H_p \vec{V} \cdot d \vec{A} \]  

choose Flow Rate for the Report Type in the Surface Integrals dialog box, select Enthalpy (in the Temperature... category) as the Field Variable, and select the surface(s) on which to integrate.
13.2.3.5. Reporting Averaged Heat Transfer Coefficients

The Surface Integrals dialog box can also be used to generate a report of averaged heat transfer coefficient \( h \) on a surface \( \frac{1}{A} \int h \, dA \).

\[ \text{Reports} \rightarrow \text{Surface Integrals} \rightarrow \text{Set Up...} \]

In the Surface Integrals dialog box, choose Area-Weighted Average for Report Type, select Surface Heat Transfer Coef. (in the Wall Fluxes... category) as the Field Variable, and select the surface.

13.2.3.6. Exporting Heat Flux Data

It is possible to export heat flux data on wall zones (including radiation) to a generic file that you can examine or use in an external program. To save a heat flux file, you will use the custom-heat-flux text command.

```
file \rightarrow \text{export} \rightarrow \text{custom-heat-flux}
```

Heat transfer data will be exported in the following free format for each face zone that you select for export:

```
zone-name nfaces
\ x_f \ y_f \ z_f \ A \ Q \ T_w \ T_c \ HTC
.
.
```

Each block of data starts with the name of the face zone (zone-name) and the number of faces in the zone (nfaces). Next there is a line for each face (that is, nfaces lines), each containing the components of the face centroid (x_f, y_f, and, in 3D, z_f), the face area (A), the heat transfer rate (Q), the face temperature (T_w), the adjacent cell temperature (T_c), and the heat transfer coefficient (HTC). If the heat transfer coefficient is calculated based on wall function (Equation 33.54 (p. 1825)), then Q is the convective heat transfer rate. Otherwise, Q will be the total heat transfer rate, including radiation heat transfer.

13.2.4. Natural Convection and Buoyancy-Driven Flows

When heat is added to a fluid and the fluid density varies with temperature, a flow can be induced due to the force of gravity acting on the density variations. Such buoyancy-driven flows are termed natural-convection (or mixed-convection) flows and can be modeled by ANSYS Fluent.

For more information about the theory behind natural convection and buoyancy-driven flows, see Natural Convection and Buoyancy-Driven Flows Theory in the Theory Guide.

13.2.4.1. Modeling Natural Convection in a Closed Domain

When you model natural convection inside a closed domain, the solution will depend on the mass inside the domain. Since this mass will not be known unless the density is known, you must model the flow in one of the following ways:

- Perform a transient calculation. In this approach, the initial density will be computed from the initial pressure and temperature, so the initial mass is known. As the solution progresses over time, this mass
will be properly conserved. If the temperature differences in your domain are large, you must follow this approach.

- Perform a steady-state calculation using the Boussinesq model (described in The Boussinesq Model (p. 766)). In this approach, you will specify a constant density, so the mass is properly specified. This approach is valid only if the temperature differences in the domain are small. If not, you use the transient approach.

**Important**

For a closed domain, you can use the *incompressible* ideal gas law only with a *fixed* operating pressure. It *cannot* be used with a floating operating pressure. You can use the *compressible* ideal gas law with either *floating* or *fixed* operating pressure.

See Floating Operating Pressure (p. 529) for more information about the floating operating pressure option.

### 13.2.4.2. The Boussinesq Model

For many natural-convection flows, you can get faster convergence with the Boussinesq model than you can get by setting up the problem with fluid density as a function of temperature. This model treats density as a constant value in all solved equations, except for the buoyancy term in the momentum equation:

\[
\rho g (\rho_0 - \rho_0) g = -\rho_0 \beta (T - T_0) g
\]

where \(\rho_0\) is the (constant) density of the flow, \(T_0\) is the operating temperature, and \(\beta\) is the thermal expansion coefficient. Equation 13.2 (p. 766) is obtained by using the Boussinesq approximation \(\rho = \rho_0 \left(1 - \beta \Delta T\right)\) to eliminate \(\rho\) from the buoyancy term. This approximation is accurate as long as changes in actual density are small; specifically, the Boussinesq approximation is valid when \(\beta (T - T_0) \ll 1\).

### 13.2.4.3. Limitations of the Boussinesq Model

The Boussinesq model should not be used if the temperature differences in the domain are large. In addition, it cannot be used with species calculations, combustion, or reacting flows.

### 13.2.4.4. Steps in Solving Buoyancy-Driven Flow Problems

The procedure for including buoyancy forces in the simulation of mixed or natural convection flows is described below.

1. Activate the calculation of heat transfer, by enabling the **Energy** option in the **Energy** dialog box.

   ![Models → Energy → Edit...](image)

2. Define the operating conditions in the **Operating Conditions** dialog box (Figure 13.3: The Operating Conditions Dialog Box (p. 767)).

   ![Cell Zone Conditions → Operating Conditions...](image)
Figure 13.3: The Operating Conditions Dialog Box

a. Enable the **Gravity** option under **Gravity**.

b. Enter the appropriate values in the $X$, $Y$, and (for 3D) $Z$ fields for **Gravitational Acceleration** for each Cartesian coordinate direction. (Note that the default gravitational acceleration in ANSYS Fluent is zero.)

c. If you are using the incompressible ideal gas law, check that the **Operating Pressure** is set to an appropriate (non-zero) value.

d. Depending on whether or not you use the Boussinesq approximation, specify the appropriate parameters described below:

   - If you are not using the Boussinesq model, the inputs are as follows:
      
      1. If necessary, enable the **Specified Operating Density** option in the **Operating Conditions** dialog box, and enter a value for the **Operating Density**. See below for details.
      
      2. Define the fluid density as a function of temperature as described in Defining Properties Using Temperature-Dependent Functions (p. 412) and Density (p. 416).

   - **Materials**
      
      1. If you are using the Boussinesq model (described in The Boussinesq Model (p. 766)) the inputs are as follows:
      
      1. Enter the **Operating Temperature** ($T_0$ in Equation 13.2 (p. 766)) in the **Operating Conditions** dialog box.
ii. Select **boussinesq** in the drop-down list for **Density** in the **Create/Edit Materials** dialog box as described in **Defining Properties Using Temperature-Dependent Functions** (p. 412) and **Density** (p. 416), and enter a constant value.

iii. Also in the **Create/Edit Materials** dialog box, enter an appropriate value for the **Thermal Expansion Coefficient** \( \beta \) in **Equation 13.2** (p. 766) for the fluid material.

Note that if your model involves multiple fluid materials you can choose whether or not to use the Boussinesq model for each material. As a result, you may have some materials using the Boussinesq model and others not. In such cases, you will need to set all the parameters described above in this step.

3. Define the boundary conditions.

   **Boundary Conditions**

   The boundary pressures that you input at pressure inlet and outlet boundaries are the redefined pressures as given by **Equation 13.3** (p. 768). In general you should enter equal pressures, \( p' \), at the inlet and exit boundaries of your ANSYS Fluent model if there are no externally imposed pressure gradients.

4. Set the parameters that control the solution.

   **Solution Methods**

   a. Select **Body Force Weighted** or **Second Order** in the drop-down list for **Pressure** under **Spatial Discretization** in the **Solution Methods** task page.

   b. If you are using the pressure-based solver, selecting **PRESTO!** as the **Spatial Discretization** method for **Pressure** is the recommended approach.

   c. Add cells near the walls to resolve boundary layers, if necessary.

See also **Solving Heat Transfer Problems** (p. 759) for information on setting up heat transfer calculations.

### 13.2.4.5. Operating Density

When the Boussinesq approximation is not used, the operating density \( \rho_0 \) appears in the body-force term in the momentum equations as \( (\rho - \rho_0)g \). This form of the body-force term follows from the re-definition of pressure in ANSYS Fluent as

\[
p_s' = p_s - \rho_0 g x
\]  

(13.3)

The hydrostatic pressure in a fluid at rest is then

\[
p_s' = 0
\]

(13.4)

#### 13.2.4.5.1. Setting the Operating Density

By default, ANSYS Fluent will compute the operating density by averaging over all cells. In some cases, you may obtain better results if you explicitly specify the operating density instead of having the solver compute it for you. For example, if you are solving a natural-convection problem with a pressure
boundary, it is important to understand that the pressure you are specifying is \( p_s' \) in Equation 13.3 (p. 768). Although you will know the actual pressure \( p_s' \), you will need to know the operating density \( \rho_0 \) in order to determine \( p_s' \) from \( p_s \). Therefore, you should explicitly specify the operating density rather than use the computed average. The specified value should, however, be representative of the average value.

In some cases the specification of an operating density will improve convergence behavior, rather than the actual results. For such cases use the approximate bulk density value as the operating density and be sure that the value you choose is appropriate for the characteristic temperature in the domain.

Note that if you are using the Boussinesq approximation for all fluid materials, the operating density \( \rho_0 \) does not appear in the body-force term of the momentum equation. Consequently, you need not specify it.

### 13.2.4.6. Solution Strategies for Buoyancy-Driven Flows

For high-Rayleigh-number flows you may want to consider the solution guidelines below. In addition, the guidelines presented in Solution Strategies for Heat Transfer Modeling (p. 761) for solving other heat transfer problems can also be applied to buoyancy-driven flows. No steady-state solution exists for some laminar, high-Rayleigh-number flows.

#### 13.2.4.6.1. Guidelines for Solving High-Rayleigh-Number Flows

When you are solving a high-Rayleigh-number flow \((Ra > 10^8)\), you should follow one of the procedures outlined below for best results.

The first procedure uses a steady-state approach:

1. Start the solution with a lower value of Rayleigh number (for example, \(10^7\)) and run it to convergence using the first-order scheme.

2. To change the effective Rayleigh number, change the value of gravitational acceleration (for example, from 9.8 to 0.098 to reduce the Rayleigh number by two orders of magnitude).

3. Use the resulting data file as an initial guess for the higher Rayleigh number and start the higher-Rayleigh-number solution using the first-order scheme.

4. After you obtain a solution with the first-order scheme you may continue the calculation with a higher-order scheme.

The second procedure uses a time-dependent approach to obtain a steady-state solution [34] (p. 2558):

1. Start the solution from a steady-state solution obtained for the same or a lower Rayleigh number.

2. Estimate the time constant as [10] (p. 2557)

\[
\tau = \frac{L}{U} \left( \frac{L^2}{a} \right)^{-1/2} = \frac{L}{\sqrt{g \beta \Delta T L}}
\]

(13.5)

where \( L \) and \( U \) are the length and velocity scales, respectively. Use a time step \( \Delta t \) such that

\[
\Delta t = \frac{\tau}{4}
\]

(13.6)
Using a larger time step $\Delta t$ may lead to divergence.

3. After oscillations with a typical frequency of $\frac{1}{\tau} = 0.05 - 0.09$ have decayed, the solution reaches steady state. Note that $\tau$ is the time constant estimated in Equation 13.5 (p. 769) and $f$ is the oscillation frequency in Hz. In general, this solution process may take as many as 5000 time steps to reach steady state.

### 13.2.4.7. Postprocessing Buoyancy-Driven Flows

The postprocessing reports of interest for buoyancy-driven flows are the same as for other heat transfer calculations. See Postprocessing Heat Transfer Quantities (p. 763) for details.

### 13.2.5. Shell Conduction Considerations

For information about shell conduction considerations, see the following sections:
13.2.5.1. Introduction
13.2.5.2. Physical Treatment
13.2.5.3. Limitations of Shell Conduction Walls
13.2.5.4. Managing Shell Conduction Walls
13.2.5.5. Initializing Shells
13.2.5.6. Locking the Temperature for Shells
13.2.5.7. Postprocessing Shells

#### 13.2.5.1. Introduction

By default, ANSYS Fluent treats walls as having zero thickness and presenting no thermal resistance to heat transfer across them. If a thickness is specified for a wall (thereby making it a thin wall, as described in Thin-Wall Thermal Resistance Parameters (p. 320)) then the appropriate thermal resistance across the wall thickness is imposed, although conduction is considered in the wall in the normal direction only. There are applications, however, where conduction in the planar directions of the wall is also important. For these applications, you have two options: you can either mesh the thickness, or you can use the shell conduction approach. Shell conduction can be used to model one or more layers of wall cells without the need to mesh the wall thickness in a preprocessor. When the shell conduction approach is utilized, you have the ability to easily switch on and off conjugate heat transfer on any wall. If you create a shell—either by enabling Shell Conduction in an individual Wall dialog box (as described in Shell Conduction (p. 323)) or by defining multiple walls as shell conduction zones using the Shell Conduction Manager dialog box (as described in Managing Shell Conduction Walls (p. 772))—and define the settings for the shell layer(s) using the Shell Conduction Model Settings dialog box, then ANSYS Fluent will automatically grow the specified layers of cells for the wall during the solution process. The cells that are grown will be either prism cells or hex cells, depending on the type of face mesh that is utilized; at no point are the cells visible in the displayed mesh.

Shell conduction can be used to account for thermal mass in transient thermal analysis problems (see Locking the Temperature for Solid and Shell Zones (p. 251) for more information). It can also be used for multiple junctions and allows heat conduction through the junctions. Shell conduction can be applied on boundary walls as well as two-sided walls.

#### 13.2.5.2. Physical Treatment

In the case where shell conduction is applied on a boundary wall, the original surface is referred to as the “wall surface” and is always adjacent to the fluid / solid cells. As part of the solution, layers of wall cells are grown away from the fluid / solid zone. These layers are numbered sequentially, starting with
the one closest to the wall surface. See Figure 13.4: A Boundary Wall with Shell Conduction (p. 771) for a visualization of how the solver treats shells.

For the most part, the boundary conditions that you specify for the boundary wall are applied to the layer surface that is furthest from the wall surface; only the internal emissivity is applied at the wall surface. The sides of the shell zone require boundary conditions as well. If the shell is connected to another wall that does not have shell conduction enabled, the shell side will take the boundary condition of the attached wall. The sides will be adiabatic if they are connected to face zones that have a boundary condition type other than wall. If the attached wall has shell conduction enabled, then the common sides at the junction will be coupled.

Figure 13.4: A Boundary Wall with Shell Conduction

The layers of cells grown for two-sided walls can be visualized in a similar way to Figure 13.4: A Boundary Wall with Shell Conduction (p. 771), except that the layer surface that is furthest from the wall surface is also adjacent to a shadow wall (which is then adjacent to the other fluid / solid zone).

Figure 13.5: A Two-Sided Wall with Shell Conduction

13.2.5.3. Limitations of Shell Conduction Walls

The following is a list of limitations for the shell conduction model:

- Shells cannot be created on non-conformal interfaces.
• Shell conduction cannot be used on moving wall zones.

• Shell conduction cannot be used with FMG initialization.

• Shell conduction is not available when the wall is set up to receive thermal data via system coupling.

• Shell conduction is not available for 2D.

• Shell conduction is available only when the pressure-based solver is used.

• Shell conducting walls cannot be split or merged. If you need to split or merge a shell conducting wall, you will need to turn off the Shell Conduction option for the wall (in the Wall dialog box), perform the split or merge operation, and then enable Shell Conduction for the new wall zones.

• The shell conduction model cannot be used on a wall zone that has been adapted. If you want to perform adaption elsewhere in the computational domain, be sure to use the mask register described in Manipulating Adaption Registers (p. 1564). This will ensure that adaption is not performed on the shell conducting wall.

• Fluxes at the ends of a shell conducting wall are not included in heat balance reports. These fluxes are accounted for correctly in the ANSYS Fluent solution, but are not listed in the flux report.

• The junction of a wall with shell conduction enabled and a non-conformal coupled wall is not supported. Such a junction will not be thermally connected, that is, there will be no heat transfer between the shell and the mesh interface wall.

### 13.2.5.4. Managing Shell Conduction Walls

The **Shell Conduction Manager** dialog box provides a convenient way for you to manage, define, and display multiple shell conduction zones. You can

- display any wall zone
- enable or disable shell conduction for a wall
- define the settings for shell conduction walls or layers, such as thickness, material, and heat generation rate

Note that you can still enable shell conduction for a wall and define the related settings using the Wall dialog box, as described in Shell Conduction (p. 323). However, the **Shell Conduction Manager** dialog box provides you with an alternative to do such activities from a single dialog box for all the walls, instead of visiting the individual Wall boundary condition dialog boxes.

**Define → Shell Conduction Manager...**
To manage shell conduction using the **Shell Conduction Manager** dialog box, perform the following steps:

1. (optional) If you have previously generated a CSV file that contains shell conduction settings for the layers of the walls, you can read it by clicking **Read...** at the bottom of the **Shell Conduction Manager** dialog box and using the dialog box that opens; otherwise, you should proceed to the steps that follow.

   Using a CSV file can be helpful when you have a large number of layers and walls. It is not necessary to create the CSV file from scratch, as you can create a simplified CSV file with sample values using the **Write...** button (as described in step 5.), and then revise the settings using a spreadsheet program. See [Shell Conduction Settings File Format (p. 2550)](#) for details about the format of the CSV file.

2. Use the **->** and **<-** buttons to move the selected zones from one list to another, and thereby define whether they are shells. Zones with shell conduction enabled are listed under **Shell Conduction Zones** and those without shell conduction are listed under **Wall Zones**. In essence, the **->** button disables shell conduction and the **<-** button enables shell conduction.

3. Click the **Display Zones** button to display the selected walls in the graphics window. Note that you can select walls with or without shell conduction. The zones will be displayed with different colors depending on the option selected in the **Mesh Colors** dialog box, which is accessible from the **Mesh Display** dialog box.

4. Define settings for all of the shells by performing the following steps:
   a. Select walls from the **Shell Conduction Zones** for which you want to define the same settings. You can use the **Shell Conduction Zone Name Pattern** to select only shell conduction zones with names...
that match a specified pattern: simply enter the text, numbers, and wildcards (*) in the text-entry box and click Match.

b. Click the Settings... button to open the **Shell Conduction Model Settings** dialog box (Figure 13.7: Shell Conduction Model Settings Dialog Box (p. 774)). There you can specify the number of layers, and then define the thickness, material, and heat generation rate for each layer.

**Important**

You must specify a non-zero thickness for every layer.

![Figure 13.7: Shell Conduction Model Settings Dialog Box](image)

c. Click **OK** to save your settings for the selected walls and close the **Shell Conduction Model Settings** dialog box.

5. If you want to save all of the settings you specified using the **Shell Conduction Manager** dialog box as a CSV file, click **Write...** and specify a name in the dialog box that opens. You can edit the shell conduction settings in this CSV file using a spreadsheet program, and then read it in this or a separate case file, as described in step 1.

Note that you have the option of disabling shell conduction in every wall with a single action, by using the following text command. This capability is available in both serial and parallel mode.

define → boundary-conditions → modify-zones → delete-all-shells

**13.2.5.5. Initializing Shells**

Shell zones can be patched using the **Patch** dialog box, as described in **Patching Values in Selected Cells** (p. 1447).

Solution Initialization → Patch...
13.2.5.6. Locking the Temperature for Shells

You can lock (or “freeze”) the temperature values for all the cells in shells and solid zones (including those to which you have a hooked an energy source through a UDF) by using the `solve/set/lock-solid-temperature?` text command, as described in Locking the Temperature for Solid and Shell Zones (p. 251).

13.2.5.7. Postprocessing Shells

In order to facilitate the postprocessing of shells, surfaces (referred to as “shell surfaces”) are created at the interface of adjacent layers, as well as at the layer surface that is furthest from the wall surface. Note that shell surfaces are not created on the sides of the shell zones or in the interior of the layers. The shell surfaces can then be selected from the `Surfaces` list available in a variety of dialog boxes (for example, the `Contours` dialog box, the `Surface Monitor` dialog box, the `Solution XY Plot` dialog box, and the `Surface Integrals` dialog box) in the same way as the surfaces for the wall and (for two-sided walls) the shadow wall. When visualized in the graphics display window, these shell surfaces will be coincident with the wall they are associated with.

The default naming convention for these shell surfaces is `<wall_name>-<c0>:<c1>`, where:

- `<wall_name>` is the name of the wall on which the layers have been grown.
- `<c0>` is the rank of the layer on the c0 side of the interface (that is, the layer closest to the wall surface).
- `<c1>` is the rank of the layer on the c1 side of the interface (that is, the layer furthest from the wall surface). Note that the layer surface that is furthest from the wall surface does not have a layer on the c1 side, and so a different convention is used: for boundary walls, `<c1>` is set to `external`; for two-sided walls, `<c1>` is set to the name of the fluid / solid adjacent to the shadow wall.

You have the ability to rename the shell surfaces, if you desire. The following figures illustrate the default naming convention, where the wall/shadow surfaces are displayed in red and the shell surfaces are displayed in black.

**Figure 13.8: Shell Surface Names for a Boundary Wall**
You can use the walls, shadow walls, and shell surfaces to display the temperature of the interfaces and adjacent cells. The Temperature... category provides two options: the temperature of the cell on the c0 side of the surface is stored as Static Temperature; and the temperature of the surface itself is stored as Wall Temperature. If a more detailed analysis of the solid zone and surfaces is required, then you should consider creating layers of solid cells in your meshing application.

The following examples illustrate how to postprocess the surfaces shown in Figure 13.8: Shell Surface Names for a Boundary Wall (p. 775):

- The Static Temperature and Wall Temperature of Bwall will provide the temperature of the fluid cells adjacent to Bwall and the temperature of the Bwall surface itself, respectively.
- The Static Temperature and Wall Temperature of Bwall-1:2 will provide the temperature of the cells of layer-1 and the temperature of the interface between layer-1 and layer-2 (that is, the Bwall-1:2 shell surface), respectively.
- The Static Temperature and Wall Temperature of Bwall-3:external will provide the temperature of the cells of layer-3 and the temperature of the layer surface that is furthest from the wall surface (that is, the Bwall-3:external shell surface), respectively.

The following examples illustrate how to postprocess the surfaces shown in Figure 13.9: Shell Surface Names for a Two-Sided Wall (p. 776):

- The Static Temperature and Wall Temperature of 2Swall-4:air will provide the temperature of the cells of layer-4 and the temperature of the interface between layer-4 and the shadow wall (that is, the 2Swall-4:air shell surface), respectively.
- The Static Temperature and Wall Temperature of 2Swall-shadow will provide the temperature of the air cells adjacent to 2Swall-shadow and the temperature of the shadow wall, respectively.

When postprocessing shells, note the following limitations:

- You should not enable Node Values when postprocessing any surfaces associated with shells (that is, the wall, shadow wall, or shell surfaces). The layers share nodes at the edges, and thus the averaging at such nodes is erroneous.
• You cannot postprocess shells in ANSYS CFD-Post, as shell surfaces are not supported.

13.3. Modeling Radiation

Information about radiation modeling is presented in the following sections:
  13.3.1. Using the Radiation Models
  13.3.2. Setting Up the P-1 Model with Non-Gray Radiation
  13.3.3. Setting Up the DTRM
  13.3.4. Setting Up the S2S Model
  13.3.5. Setting Up the DO Model
  13.3.6. Defining Material Properties for Radiation
  13.3.7. Defining Boundary Conditions for Radiation

  13.3.9. Postprocessing Radiation Quantities
  13.3.10. Solar Load Model

For theoretical information about the radiation models in ANSYS Fluent, refer to Modeling Radiation in the Theory Guide.

13.3.1. Using the Radiation Models

The procedure for setting up and solving a radiation problem is outlined below, and described in detail in referenced sections. Steps that are relevant only for a particular radiation model are noted as such. The steps that are pertinent to radiation modeling, are shown here. For information about inputs related to other models that you are using in conjunction with radiation, see the appropriate sections for those models.

1. Activate radiative heat transfer by selecting a radiation model (Rosseland, P1, Discrete Transfer (DTRM), Surface to Surface (S2S), or Discrete Ordinates) under Model in the Radiation Model dialog box (Figure 13.10: The Radiation Model Dialog Box (DO Model) (p. 778)).
**Important**

The **Rosseland** model can be used only with the pressure-based solver.

Note that when the P-1, the DTRM, the S2S, or the DO model is activated, the **Radiation Model** dialog box expands to show additional parameters. These parameters will not appear if you select the Rosseland model. If you are running a 3D case, you will have the added option of using the solar load model. The solar load options will be displayed in the dialog box, below the radiation model settings.

When the radiation model is active, the radiation fluxes will be included in the solution of the energy equation at each iteration. If you set up a problem with the radiation model turned on, and you then decide to turn it off completely, you must select the **Off** button in the **Radiation Model** dialog box.

Note that when you enable a radiation model, ANSYS Fluent will automatically enable the energy equation so that step is not needed.

2. Set the appropriate radiation parameters.
   a. If you are modeling non-gray radiation using the P-1 model, define the non-gray radiation parameters as described in *Setting Up the P-1 Model with Non-Gray Radiation* (p. 779).
   b. If you are using the DTRM, define the ray tracing as described in *Setting Up the DTRM* (p. 780).
c. If you are using the S2S model, define the surface clusters and view factors settings and compute or read the view factors as described in Setting Up the S2S Model (p. 782).

d. If you are using the DO model, choose **DO/Energy Coupling** if desired, define the angular discretization as described in Setting Up the DO Model (p. 795) and, if relevant, define the non-gray radiation parameters as described in Defining Non-Gray Radiation for the DO Model (p. 795).

3. Define the material properties as described in Defining Material Properties for Radiation (p. 798).

4. Define the boundary conditions as described in Defining Boundary Conditions for Radiation (p. 798). If your model contains a semi-transparent medium, see the information below on setting up semi-transparent media.

5. Set the parameters that control the solution (DTRM, DO, S2S, and P-1 only) as described in Solution Strategies for Radiation Modeling (p. 807).

6. Run the solution as described in Running the Calculation (p. 810).

7. Postprocess the results as described in Postprocessing Radiation Quantities (p. 811).

### 13.3.2. Setting Up the P-1 Model with Non-Gray Radiation

If you want to model non-gray radiation using the P-1 model, you can specify the **Number of Bands** under **Non-Gray Model** in the expanded Radiation Model dialog box (Figure 13.11: The Radiation Model Dialog Box (Non-Gray P-1 Model) (p. 779)). By default, the **Number of Bands** is set to zero, indicating that only gray radiation will be modeled. Because the cost of computation increases directly with the number of bands, you should try to minimize the number of bands used. When a non-zero **Number of Bands** is specified, the Radiation Model dialog box will expand once again to show the **Wavelength Intervals**. For each wavelength band, you can specify a **Name**, as well as the **Start** and **End** wavelength of the band in μm. Note that the wavelength bands are specified for vacuum (μ = 1). For more information about non-gray radiation calculations, see Defining Non-Gray Radiation for the DO Model (p. 795).

![Figure 13.11: The Radiation Model Dialog Box (Non-Gray P-1 Model)](image)

ANSYS Fluent allows you to use a user-defined function (UDF) to modify the emissivity weighting factor $F(0 \rightarrow n\lambda T) - F(0 \rightarrow n\lambda T')$ (which otherwise defaults to the black body emission factor obtained from a standard Planck distribution). The emissivity weighting factor appears in the emission term of

the radiative transfer equation for the non-gray model, as shown in Equation 5.25 in the Theory Guide. For more information, see the UDF Manual.

13.3.3. Setting Up the DTRM

For information about setting up the DTRM, see the following sections:
  13.3.3.1. Defining the Rays
  13.3.3.2. Controlling the Clusters
  13.3.3.3. Controlling the Rays
  13.3.3.4. Writing and Reading the DTRM Ray File
  13.3.3.5. Displaying the Clusters

13.3.3.1. Defining the Rays

When you select the Discrete Transfer model and click OK in the Radiation Model dialog box, the DTRM Rays dialog box (Figure 13.12: The DTRM Rays Dialog Box (p. 780)) will open automatically. If you need to modify the current settings later in the problem setup or solution procedure, you can open this dialog box manually using the Define/DTRM Rays... menu item.

Figure 13.12: The DTRM Rays Dialog Box

In this dialog box you will set parameters for and create the rays and clusters discussed in The DTRM Equations in the Theory Guide.

The procedure is as follows:

1. To control the number of radiating surfaces and absorbing cells, set the Cells Per Volume Cluster and Faces Per Surface Cluster. (See the explanation below.)

2. To control the number of rays being traced, set the number of Theta Divisions and Phi Divisions. (Guidelines are provided below.)

3. When you click OK in the DTRM Rays dialog box, The Select File Dialog Box (p. 15) will open prompting you for the name of the “ray file”. After you have specified the file name and chosen whether to write a binary ray file, ANSYS Fluent will write the ray file and then read it afterward. During the write process the status of the DTRM ray tracing will be reported in the ANSYS Fluent console. For example:

Completed 25% tracing of DTRM rays
Completed 50% tracing of DTRM rays
Completed 75% tracing of DTRM rays
Completed 100% tracing of DTRM rays
See following sections for details on DTRM Rays dialog box inputs.

**Important**

If you cancel the DTRM Rays dialog box without writing and reading the ray file, the DTRM will be disabled.

### 13.3.3.2. Controlling the Clusters

Your inputs for **Cells Per Volume Cluster** and **Faces Per Surface Cluster** will control the number of radiating surfaces and absorbing cells. By default, each is set to 1, so the number of surface clusters (radiating surfaces) will be the number of boundary faces, and the number of volume clusters (absorbing cells) will be the number of cells in the domain. For small 2D problems, these are acceptable numbers, but for larger problems you will want to reduce the number of surface and/or volume clusters in order to reduce the ray-tracing expense. See Clustering in the Theory Guide for details about clustering.

### 13.3.3.3. Controlling the Rays

Your inputs for **Theta Divisions** and **Phi Divisions** will control the number of rays being traced from each surface cluster (radiating surface).

**Theta Divisions** defines the number of discrete divisions in the angle $\theta$ used to define the solid angle about a point $P$ on a surface. The solid angle is defined as $\theta$ varies from 0 to 90 degrees (in the Theory Guide), and the default setting of 1 for the number of discrete settings implies that there will be one ray traced from the surface.

**Phi Divisions** defines the number of discrete divisions in the angle $\phi$ used to define the solid angle about a point $P$ on a surface. The solid angle is defined as $\phi$ varies from 0 to 360 degrees (Figure 5.2: Angles $\theta$ and $\phi$ Defining the Hemispherical Solid Angle About a Point P in the Theory Guide). The default setting of 4 implies that each ray traced from the surface will be located at a 90$^\circ$ angle, and in combination with the default setting for **Theta Divisions**, above, implies that 4 rays will be traced from each surface control volume. In many cases, it is recommended that you at least double the number of divisions in $\theta$ and $\phi$.

### 13.3.3.4. Writing and Reading the DTRM Ray File

After you have activated the DTRM and defined all of the parameters controlling the ray tracing, you must create a ray file, which will be read back in and used during the radiation calculation. The ray file contains a description of the ray traces (path lengths, cells traversed by each ray, etc.). This information is stored in the ray file, instead of being recomputed, in order to speed up the calculation process.

By default, a binary ray file will be written. You can also create text (formatted) ray files by turning off the Write Binary Files option in The Select File Dialog Box (p. 15).

**Important**

Do not write or read a compressed ray file, because ANSYS Fluent will not be able to access the ray tracing information properly from a compressed ray file.
The ray filename must be specified to ANSYS Fluent only once. Thereafter, the filename is stored in your case file and the ray file will be automatically read into ANSYS Fluent whenever the case file is read. ANSYS Fluent will remind you that it is reading the ray file after it finishes reading the rest of the case file by reporting its progress in the console.

Note that the ray filename stored in your case file may not contain the full name of the directory in which the ray file exists. The full directory name will be stored in the case file only if you initially read the ray file through the GUI (or if you typed in the directory name along with the filename when using the text interface). In the event that the full directory name is absent, the automatic reading of the ray file may fail (since ANSYS Fluent does not know in which directory to look for the file), and you will need to manually specify the ray file, using the File/Read/DTRM Rays... menu item. The safest approaches are to use the GUI when you first read the ray file or to supply the full directory name when using the text interface.

Important

You should recreate the ray file whenever you do anything that changes the mesh, such as:

- change the type of a boundary zone
- adapt or reorder the mesh
- scale the mesh

You can open the DTRM Rays dialog box directly with the Define/DTRM Rays... menu item.

13.3.3.5. Displaying the Clusters

Once a ray file has been created or read in manually, you can click the Display Clusters button in the DTRM Rays dialog box to graphically display the clusters in the domain. See Displaying Rays and Clusters for the DTRM (p. 813) for additional information about displaying rays and clusters.

13.3.4. Setting Up the S2S Model

When you select the Surface to Surface (S2S) model, the Radiation Model dialog box will expand to show additional parameters (see Figure 13.13: The Radiation Model Dialog Box (S2S Model) (p. 783)). In these additional group boxes, you will set the solution parameters (see S2S Solution Parameters (p. 809) for further details), access the view factors and clustering settings, and compute the view factors for your problem or read previously computed view factors into ANSYS Fluent.
The S2S radiation model is very expensive in terms of computation effort and memory requirements when there are a large number of radiating surfaces. You can reduce the number of radiating surfaces by grouping faces together to form surface clusters. The surface cluster information (coordinates and connectivity of the nodes, surface cluster IDs) is used by ANSYS Fluent in the radiosity calculations and to compute the view factors.

**Important**

- You should recreate the surface cluster information whenever you do anything that changes the mesh, such as:
  - change the type of a boundary zone
  - reorder the mesh
  - scale the mesh

Note that you do not need to recalculate view factors after shell conduction at any wall has been enabled or disabled (see Thermal Boundary Conditions at Walls (p. 318) for more information about shell conduction). However, enabling or disabling shell conduction in the parallel version of Fluent does cause a migration of cells and hence a change in the partition. Whenever there is cell migration, the previously read view factor file is no longer valid, and the view factor file needs to be read again using either the Read Existing File button in the Radiation Model dialog box or the File/Read/View Factors... menu item.
• ANSYS Fluent will warn you to recreate the cluster/view factor file if a boundary zone has been changed from a wall to an internal wall (or vice versa), or if a boundary zone has been merged, separated, or fused.

13.3.4.1. View Factors and Clustering Settings

You can use the View Factors and Clustering dialog box (Figure 13.14: The View Factors and Clustering Dialog Box (p. 784)) to define how the surface clusters are formed and how the view factors are calculated for the S2S model. To open this dialog box, click Settings... in the View Factors and Clustering group box in the Radiation Model Dialog Box (p. 1917) (Figure 13.13: The Radiation Model Dialog Box (S2S Model) (p. 783)) or use the File/Write/Surface Clusters... menu item.

Figure 13.14: The View Factors and Clustering Dialog Box

13.3.4.1.1. Forming Surface Clusters

You can set the number of faces per surface cluster (FPSC) for each flow boundary (that is, exhaust fan, inlet vent, intake fan, outlet vent, mass-flow inlet, pressure far-field, pressure inlet, pressure outlet, outflow, and velocity inlet boundary) and wall that is adjacent to a fluid zone; in this way, you can control the number of radiating surfaces and (if you select Cluster to Cluster for Basis) view factor
surfaces. By default, the FPSC value is set to 1 everywhere, so the number of surface clusters (radiating/view factor surfaces) will be equal to the number of boundary faces. For small 2D problems, this is an acceptable number. For larger problems, you may want to reduce the number of surface clusters (that is, increase the FPSC) to reduce both the size of the view factor file and the memory requirement. Such a reduction in the number of clusters, however, comes at the cost of some accuracy. Note that for a thermally coupled mesh interface (that is, a fluid-fluid interface with Coupled Wall enabled, or a solid-fluid interface), the FPSC is always set to 1. See Clustering in the Theory Guide for details about clustering.

**Important**

If you plan to use the cluster to cluster basis for the view factor calculation, be sure that the FPSC values are appropriate for both the radiosity calculation and the view factors.

Note that during the creation of a cluster on a non-conformal interface, its parent thread is taken into the consideration; it may happen that the cluster is somewhat larger than its child face, which may lead some inaccuracy in the flux calculation.

The Clustering group box in the View Factors and Clustering dialog box (Figure 13.14: The View Factors and Clustering Dialog Box (p. 784)) provides two methods for revising the default FPSC values:

- manual
- automatic

If you select Manual in the Options group box, you can specify an FPSC value for all flow boundaries in the Faces per Surface Cluster for Flow Boundary Zones number-entry box in the Manual group box. If you then click Apply to All Walls, you will apply this value to all wall zones that are adjacent to fluid zones as well. For a wall that requires a different FPSC value (that is, you may want a lower value for walls in critical areas, and higher values in non-critical areas), you will need to open the boundary condition dialog box (Figure 13.15: The Wall Dialog Box (p. 786)) for that particular wall and modify the Faces Per Surface Cluster in the S2S Parameters group box of the Radiation tab. Note that the Radiation tab also allows you to specify whether the wall participates in the view factor calculation, as described in Specifying Boundary Zone Participation (p. 789).
**Important**

The **Faces Per Surface Cluster** number-entry box will not be visible in the GUI on wall boundary zones that are attached to a solid.

Using the manual method to specify the FPSC values for walls can become very cumbersome if the model involves a large number of radiating faces, which is typically the case in underhood models. In such circumstances, it is recommended that you use the automatic clustering method instead. In this method, different FPSC values are assigned to the walls automatically, based on the distance of the walls from and the FPSC values of the walls that are defined as critical. The steps you will need to take are as follows:

1. Select **Automatic** from the **Options** list in the **View Factors and Clustering** dialog box.

2. For each wall that you deem critical, perform the following actions in the **Wall** dialog box (Figure 13.15: The Wall Dialog Box (p. 786)):
   
   a. Click the **Radiation** tab.

   b. Enter an appropriate value for **Faces Per Surface Cluster** in the **S2S Parameters** group box.

   c. Enable the **Critical Zone** option.

   d. Click **OK** to close the **Wall** dialog box.
3. Enter the **Maximum Faces per Surface Cluster** value in the **View Factors and Clustering** dialog box and click the **Compute** button. ANSYS Fluent will automatically calculate and update the **Faces Per Surface Cluster** values for all **Wall** dialog boxes adjacent to fluid zones that do not have **Critical Zone** enabled, without computing the clusters.

4. You can check the automatically assigned FPSC values by opening the boundary condition dialog box of any non-critical wall of interest and examining the value for **Faces Per Surface Cluster** in the **S2S Parameters** group box of **Radiation** tab. You can manually modify the value for **Faces Per Surface Cluster** as necessary.

### 13.3.4.1.1.1. Setting the Split Angle for Clusters

Whether you set the FPSC value manually or automatically, you have the option of modifying the cutoff or “split” angle between adjacent face normals for the purpose of controlling surface clustering. The split angle sets the limit for which adjacent faces are clustered. A smaller split angle allows for a better representation of the view factor. By default, no surface cluster will contain any face that has a face normal greater than 20°. To modify the value of this parameter, you can use the **split-angle** text command:

```plaintext
define → models → radiation → s2s-parameters → split-angle
```

or

```plaintext
file → write-surface-clusters → split-angle
```

### 13.3.4.1.2. Setting Up the View Factor Calculation

You can control many aspects of how the view factors are calculated for your S2S model: how surfaces are defined; the computational method and related parameters; whether surface blocking will be accounted for; and which boundary zones will participate in the calculation. All of these controls are available in the **View Factors** group box in the **View Factors and Clustering** dialog box (Figure 13.14: The View Factors and Clustering Dialog Box (p. 784)), and are described in the sections that follow.

### 13.3.4.1.2.1. Selecting the Basis for Computing View Factors

ANSYS Fluent allows two ways to define the surfaces used for the view factor calculation, as described in **Clustering and View Factors** in the **Theory Guide**. If you want the surfaces to be the boundary faces of the mesh, select **Face to Face** for **Basis** in the **View Factor** group box of the **View Factors and Clustering** dialog box. This is the default selection.

Alternatively, you can select **Cluster to Cluster** for **Basis**, in order to reduce the computational expense and storage requirements. In this case, the surfaces used to calculate the view factors are the clusters defined by the settings in the **Cluster** group box of the **View Factors and Clustering** dialog box. The reduction in computational time will be proportional to the number of surface clusters used in the view factor calculation. The trade-offs of using the cluster to cluster basis for the calculation are that the accuracy may decrease, and the following limitations apply:

- The mesh must be 3D.
- Only the hemicube method can be used, as described in **Selecting the Method for Computing View Factors** (p. 788).
- You cannot subdivide the faces as part of the hemicube method parameters, which can cause the view factors to be overestimated.
• Polyhedral meshes are restricted to 1 face per surface cluster.

13.3.4.1.2.2. Selecting the Method for Computing View Factors

ANSYS Fluent provides two methods for computing view factors: the ray tracing method (which is selected by default) and the hemicube method. The following limitations apply:

• The hemicube method is available only for 3D and axisymmetric cases.

• The hemicube method should not be used when any of the zones are defined as periodic or symmetry boundaries, as these types are not currently supported.

• The ray tracing method is only available when Face to Face is selected for Basis.

The hemicube method uses a differential area-to-area method and calculates the view factors on a row-by-row basis. The view factors calculated from the differential areas are summed to provide the view factor for the whole surface. This method originated from the use of the radiosity approach in the field of computer graphics [17] (p. 2557).

To use the hemicube method to compute the view factors, select Hemicube from the Method list in the View Factors and Clustering dialog box. It is recommended that you use the hemicube method for large, complex models with few obstructing surfaces between the radiating surfaces.

The hemicube method is based upon three assumptions about the geometry of the surfaces: aliasing, visibility, and proximity. To validate these assumptions, you can specify three different hemicube parameters, which can help you obtain better accuracy in calculating view factors. In most cases, however, the default settings will be sufficient.

• Aliasing—The true projection of each visible face onto the hemicube can be accurately accounted for by using a finite-resolution hemicube. As described previously, the faces are projected onto a hemicube. Because of the finite resolution of the hemicube, the projected areas and resulting view factors may be overestimated or underestimated. Aliasing effects can be reduced by increasing the value of the Resolution of the hemicube in the Parameters group box.

• Visibility—The visibility between any two faces does not change. In some cases, face i has a complete view of face k from its centroid, but some other face j occludes much of face k from face i. In such a case, the hemicube method will overestimate the view factor between face i and face k calculated from the centroid of face i. This error can be reduced by subdividing face i into smaller subfaces. You can specify the number of subfaces by entering a value for Subdivisions in the Parameters group box. Note that you cannot subdivide the faces when Cluster to Cluster is selected for Basis.

• Proximity—The distance between faces is great compared to the effective diameter of the faces. The proximity assumption is violated whenever faces are close together in comparison to their effective diameter or are adjacent to one another. In such cases, the distances between the centroid of one face and all points on the other face vary greatly. Since the view factor dependence on distance is non-linear, the result is a poor estimate of the view factor.

In the Parameters group box, you can set a limit for the Normalized Separation Distance, which is the ratio of the minimum face separation to the effective diameter of the face. If the computed normalized separation distance is less than the specified value, the face will then be divided into a number of subfaces until the normalized distances of the subfaces are greater than the specified value. Alternatively, you can specify the number of subfaces to create for such faces by entering a value for Subdivisions.
While the hemicube method projects radiating surfaces onto a hemicube, the ray tracing method instead traces rays through the centers of every hemicube face to determine which surfaces are visible through that face. Also, the ray tracing method is OpenMP parallelized and will therefore use all available processors when performing the ray tracing calculations (for further details, visit http://www.openmp.org). As a result, the calculation time is reduced for large, complex geometries that have obstructions between the radiating surfaces (such as automotive underhood simulations). Note that the ray tracing method does not subdivide the faces (as can be done when using the hemicube method by setting the Subdivisions or Normalized Separation Distance parameters), and so the view factors may be less accurate than those calculated using the hemicube method for surfaces that have a normalized separation distance less than 5.

To use the ray tracing method to compute the view factors, select Ray Tracing from the Method list in the View Factors and Clustering dialog box. You can adjust the value of the Resolution in the Parameters group box in order to reduce the impact of aliasing effects, as described previously.

### 13.3.4.1.2.3. Accounting for Blocking Surfaces

View factor calculations depend on the geometric orientations of surface pairs with respect to each other. Two situations may be encountered when examining surface pairs:

- If there is no obstruction between the surface pairs under consideration, then they are referred to as “nonblocking” surfaces.

- If there is another surface blocking the views between the surfaces under consideration, then they are referred to as “blocking” surfaces. Blocking will change the view factors between the surface pairs and require additional checks to compute the correct value of the view factors.

For cases with blocking surfaces, select Blocking from the Surfaces list in the View Factors and Clustering dialog box. For cases with nonblocking surfaces, you can choose either Blocking or Nonblocking without affecting the accuracy. However, it is better to choose Nonblocking for such cases, as it takes less time to compute.

### 13.3.4.1.2.4. Specifying Boundary Zone Participation

You can choose to exclude walls and inlet and exit boundaries from participating in the view factor calculation. If you are unsure whether it is necessary to calculate view factors for a particular boundary zone ahead of time, it is recommended that you allow it to participate; you can always reverse this decision as part of a future calculation run.

There are two ways in which you can enable/disable the participation of walls and inlet and exit boundaries in the view factor calculation. One of those ways is to use the Participates in View Factor Calculation option in the Radiation tab of the boundary condition dialog box. The other method is to use the Participating Boundary Zones dialog box (Figure 13.16: The Participating Boundary Zones Dialog Box (p. 790)), which is accessed by clicking the Select... button next to the Zones Participating in View Factor Calculation label in the View Factors and Clustering dialog box. For cases that are comprised of a very large number of zones, such as underhood applications, the latter method is recommended.

---

**Important**

If you compute the view factors and then later alter which boundary zones participate in the view factor calculation, you must recompute the view factors so that the data is up to date.
The **Participating Boundary Zones** dialog box allows you to easily specify those zones that are participating or non-participating without having to visit the boundary conditions dialog box of each zone. For cases that have a small number of boundary zones, you can simply select the zones that you do not want to participate in the view factor calculation from the **Participating Boundary Zones** list and click the arrow button that points to the right, so that the zones are moved to the **Non-Participating Boundary Zones** list; if you make an error, you can always reverse this process (that is, select a zone in the **Non-Participating Boundary Zones** list and click the arrow button that points to the left). This can be cumbersome for cases that have a large number of boundary zones, and so the following procedure is recommended instead:

1. Make sure that your clustering options (see *Forming Surface Clusters* (p. 784)) are appropriate for your view factor settings:
   
   a. Select **Automatic** from the **Options** list in the **Clustering** group box of the **View Factors and Clustering** dialog box, as this enables some GUI items in the **Participating Boundary Zones** dialog box.

   **Important**

   Note that if you do not want to use the **Automatic** option for the clustering, you can revert to the **Manual** option after you are done using the **Participating Boundary Zones** dialog box.
b. Verify that the walls you specified as critical (by enabling the Critical Zone option in the Radiation tab of the boundary condition dialog box) also correspond to those that are critical for the view factor calculation. You must have specified at least one critical zone for the steps that follow.

2. Click the Compute button in the Maximum Distance from Critical Zone dialog box, to update the value displayed for To All Other Zones. This value represents the maximum distance between the centroids of a critical zone and a non-critical zone in the mesh; it is for information purposes only, and cannot be edited in this dialog box.

3. Based on the value displayed for To All Other Zones, enter a threshold value for To Participating Zones. The value you enter will specify the maximum distance allowed between the centroids of a critical zone and a zone that participates in the view factor calculation. Then click the Apply button to move all zones beyond this distance into the Non-Participating Boundary Zones list.

4. Review the zones displayed in the Participating Boundary Zones and Non-Participating Boundary Zones lists. If necessary, select zones in these lists and use the arrow buttons to move them to the appropriate list, as described previously.

If at any point you want to visually identify zones displayed in the Participating Boundary Zones and Non-Participating Boundary Zones lists, select the zones and click the Display Zones button. Only the selected zones will be displayed in the graphics window.

If any zones are displayed in the Non-Participating Boundary Zones list, ensure to enter an appropriate temperature for Non-Participating Boundary Zones Temperature. In most cases the appropriate value is the ambient temperature, which by default is assumed to be 300 K.

After you have specified which zones do not participate in view factor calculation and set their temperature, click OK to store the settings and close the Participating Boundary Zones dialog box. You can then proceed to computing the view factors, as described in the section that follows.

13.3.4.2. Computing View Factors

ANSYS Fluent can compute the view factors for your problem in the current session and save them to a file for use in the current session and future sessions. Alternatively, you can save the surface cluster information and view factor parameters to a file, calculate the view factors outside ANSYS Fluent, and then read the view factors into ANSYS Fluent. These methods for computing view factors are described in the following sections.

**Important**

For large meshes or complex models, it is recommended that you calculate the view factors outside ANSYS Fluent and then read them into ANSYS Fluent before starting your simulation.

**Note**

You can accelerate view factor calculations by using ANSYS Fluent in parallel. For more information see Accelerating View Factor Calculations for General Purpose Computing on Graphics Processing Units (GPGPUs) (p. 1885).
13.3.4.2.1. Computing View Factors Inside ANSYS Fluent

To compute view factors in your current ANSYS Fluent session, you must first set the parameters for the view factor calculation in the View Factors and Clustering dialog box (see View Factors and Clustering Settings (p. 784) for details) and click OK to save them. When you have set the view factor and surface cluster parameters, click the Compute/Write/Read... button in the View Factors and Clustering group box of the Radiation Model dialog box. A Select File dialog box will open, prompting you for the name of the file in which ANSYS Fluent should save the surface cluster information and the view factors. After you have specified the file name, ANSYS Fluent will write the surface cluster information to the file. ANSYS Fluent will use the surface cluster information to compute the view factors, save the view factors to the same file, and then automatically read the view factors. The ANSYS Fluent console will report the status of the view factor calculation. For example:

Completed 25% calculation of view factors
Completed 50% calculation of view factors
Completed 75% calculation of view factors
Completed 100% calculation of view factors

Important

• You must recompute the view factors if you take any of following actions after the initial computation:
  – if you alter which boundary zones participate in the view factor calculation (either by using the Participating Boundary Zones dialog box, or by enabling / disabling the Participates in View Factor Calculation option in the Radiation tab of the boundary condition dialog box)
  – if you scale or unscale the mesh by using the Scale Mesh dialog box

• The view factor file format for this version of ANSYS Fluent is known as the compressed row format (CRF) and is a more efficient way of writing view factors than in versions that are prior to Fluent 6.4. In the CRF format, only non-zero view factors with their associated cluster IDs are stored to the file. This reduces the size of the .s2s file, and reduces the time it takes to read the file into ANSYS Fluent. While the CRF file format is the default, you can still use the older file format if necessary. Contact your support engineer for more information.

• View factors using ray tracing are computed with the MPI/OpenMP hybrid model for parallel runs. By default, all the available cores within a machine are used as OpenMP threads. You can overwrite this option by setting the desired number of cores or processors to be used as OpenMP threads using the (%set-openmp-threads N) scheme command, where N is the number of cores or processors to be used as OpenMP threads. You can query the OpenMP threads being set using the (%get-openmp-threads) scheme command.

Note

For cases that use the S2S model and contain non-conformal interfaces, if the mesh interfaces are defined after the case has been read, then the intersection of the interface zones will occur during the initialization process, which will cause relabeling of faces throughout the domain. If you attempt to compute view factors before solution initial-
ization in such a case, then the following message will be displayed in the console and the view factors will be computed automatically during solution initialization to avoid a mismatch with the case file:

Intersection zones for non-conformal interfaces are not created.
View factors will be computed during solution initialization.

13.3.4.2.2. Computing View Factors Outside ANSYS Fluent

To compute view factors outside ANSYS Fluent, you must save the surface cluster information and view factor parameters to a file.

File → Write → Surface Clusters...

ANSYS Fluent will open the View Factors and Clustering dialog box, where you will set the view factor and surface cluster parameters (see View Factors and Clustering Settings (p. 784) for details). When you click OK in the View Factors and Clustering dialog box, a Select File dialog box will open, prompting you for the name of the file in which ANSYS Fluent should save the surface cluster information and view factor parameters to the file. If the specified Filename ends in .gz or .Z, appropriate file compression will be performed.

To calculate the view factors outside ANSYS Fluent, enter one of the following commands:

• For the serial solver:

  utility viewfac inputfile

  where inputfile is the filename, or the correct path to the filename, for the surface cluster information and view factor parameters file that you saved from ANSYS Fluent. You can then read the view factors into ANSYS Fluent, as described below.

• For the parallel solver:

  – Viewfac utility module:

    utility viewfac -tnprocs [-pinterconnect] [-mpi=mpi type] -cnf= hosts_file inputfile

    where inputfile is the filename for which you will need to provide the full path.

  – Raytracing utility module:

    utility raytracing -tnprocs [-pinterconnect] [-mpi=mpi type] -cnf= hosts_file [-ompthreads=N] inputfile

    where inputfile is the filename for which you will need to provide the full path.

  On Windows:

  -tnprocs specifies the number of processes to use. When the -cnf option is present, the hosts file argument is used to determine which computers to use for the parallel job. For example, if there are 8 computers listed in the hosts file and you want to run a job with 4 processes, set nprocs to 4 (that is -t 4) and ANSYS Fluent will use the first 4 machines listed in the hosts file. Note that this does not apply to the Compute Cluster Server (CCS).
-pinterconnect (optional) specifies the type of interconnect. The ethernet interconnect is used by default if the option is not explicitly specified. See Table 34.2: Supported Interconnects for the Windows Platform (p. 1846), Table 34.3: Available MPIs for Windows Platforms (p. 1846), and Table 34.4: Supported MPIs for Windows Architectures (Per Interconnect) (p. 1846) for more information.

-mpi=mpi_type (optional) specifies the type of MPI. If the option is not specified, the default MPI for the given interconnect (HP MPI) will be used (the use of the default MPI is recommended). The available MPIs for Windows are shown in Table 34.3: Available MPIs for Windows Platforms (p. 1846).

-cnf=hosts file specifies the hosts file, which contains a list of the computers on which you want to run the parallel job. You will need to supply the full pathname to the file, or you can use an explicit host list such as -cnf=host1,host2,...,hostn

-ompthreads=N (optional) where N is the desired number of OpenMP threads to be used per machine.

**On Linux:**
-tnprocs specifies the number of processes to used. When the -cnf option is present, the hosts file argument is used to determine which computers to use for the parallel job. For example, if there are 10 computers listed in the hosts file and you want to run a job with 5 processes, set nprocs to 5 (that is -t5) and ANSYS Fluent will use the first 5 machines listed in the hosts file.

-mpi=mpi_type (optional) specifies the type of MPI. If the option is not specified, the default MPI for the given interconnect will be used (the use of the default MPI is recommended). The available MPIs for Linux are shown in Table 34.6: Available MPIs for Linux Platforms (p. 1851). 

-cnf=hosts file specifies the hosts file, which contains a list of the computers on which you want to run the parallel job. You will need to supply the full pathname to the file.

-ompthreads=N (optional) where N is the desired number of OpenMP threads to be used per machine.

**13.3.4.3. Reading View Factors into ANSYS Fluent**

If the view factors for your problem have already been computed (either inside or outside ANSYS Fluent) and saved to a file, you can read them into ANSYS Fluent. To read in the view factors, click **Read Existing File...** button in the **View Factors and Clustering** group box of the **Radiation Model** dialog box. A **Select File** dialog box will open where you can specify the name of the file containing the view factors. Alternatively, you can read the view factors file using the **File/Read/View Factors...** menu item.

**Important**

While the previous .s2s view factor file format can still be read seamlessly into ANSYS Fluent, there is now a more efficient compressed row format (CRF) that can be read into ANSYS Fluent (see the section on Computing View Factors Inside ANSYS Fluent). You can take advantage of the reduced size of the CRF file and therefore the reduced time it takes to read the file into ANSYS Fluent, by converting the existing old file format to the new format (without having to recompute the view factors) using the following command at the command prompt in your working directory:

```
utility viewfac -cl -o new.s2s.gz old.s2s.gz
```
where new.s2s.gz is the CRF format to which you want the old file format (old.s2s.gz) converted.

13.3.5. Setting Up the DO Model

For information about setting up the DO model, see the following sections:

- 13.3.5.1. Angular Discretization
- 13.3.5.2. Defining Non-Gray Radiation for the DO Model
- 13.3.5.3. Enabling DO/Energy Coupling

13.3.5.1. Angular Discretization

When you select the Discrete Ordinates model, the Radiation Model dialog box will expand to show inputs for Angular Discretization (see Figure 13.10: The Radiation Model Dialog Box (DO Model) (p. 778)). In this section, you will set parameters for the angular discretization and pixelation described in Angular Discretization and Pixelation in the Theory Guide.

Theta Divisions ($N_\theta$) and Phi Divisions ($N_\phi$) will define the number of control angles used to discretize each octant of the angular space (see Figure 5.3: Angular Coordinate System in the Theory Guide). Note that higher levels of discretization are recommended for problems where specular exchange of radiation is important to increase the likelihood of the correct beam direction being captured. For a 2D model, ANSYS Fluent will solve only 4 octants (due to symmetry); therefore, a total of $4N_\theta N_\phi$ directions $\vec{s}$ will be solved. For a 3D model, 8 octants are solved, resulting in $8N_\theta N_\phi$ directions $\vec{s}$. By default, the number of Theta Divisions and the number of Phi Divisions are both set to 2. For most practical problems, these settings are acceptable, however, a setting of 2 is considered to be a coarse estimate. Increasing the discretization of Theta Divisions and Phi Divisions to a minimum of 3, or up to 5, will achieve more reliable results. A finer angular discretization can be specified to better resolve the influence of small geometric features or strong spatial variations in temperature, but larger numbers of Theta Divisions and Phi Divisions will add to the cost of the computation.

Theta Pixels and Phi Pixels are used to control the pixelation that accounts for any control volume overhang (see Figure 5.7: Pixelation of Control Angle in the Theory Guide and the figures and discussion preceding it). For problems involving gray-diffuse radiation, the default pixelation of $1 \times 1$ is usually sufficient. For problems involving symmetry, periodic, specular, or semi-transparent boundaries, a pixelation of $3 \times 3$ is recommended and will achieve acceptable results. The computational effort, as a result of increasing the pixelation, is less than the computational effort caused by increasing the divisions. You should be aware, however, that increasing the pixelation adds to the cost of computation.

**Important**

Note that pixelations are applied to boundary faces by default.

13.3.5.2. Defining Non-Gray Radiation for the DO Model

If you want to model non-gray radiation using the DO model, you can specify the Number of Bands ($N$) under Non-Gray Model in the expanded Radiation Model dialog box (Figure 13.17: The Radiation Model Dialog Box (Non-Gray DO Model) (p. 796)). For a 2D model, ANSYS Fluent will solve $4N_\theta N_\phi N$ directions. For a 3D model, $8N_\theta N_\phi N$ directions will be solved. By default, the Number of Bands is set to zero, indicating that only gray radiation will be modeled. Because the cost of computation increases
directly with the number of bands, you should try to minimize the number of bands used. In many cases, the absorption coefficient or the wall emissivity is effectively constant for the wavelengths of importance in the temperature range of the problem. For such cases, the gray DO model can be used with little loss of accuracy. For other cases, non-gray behavior is important, but relatively few bands are necessary. For typical glasses, for example, two or three bands will frequently suffice.

When a non-zero **Number of Bands** is specified, the **Radiation Model** dialog box will expand once again to show the **Wavelength Intervals** (Figure 13.17: The Radiation Model Dialog Box (Non-Gray DO Model) (p. 796)). You can specify a **Name** for each wavelength band, as well as the **Start** and **End** wavelength of the band in \( \mu \text{m} \). Note that the wavelength bands are specified for vacuum \((\mu = 1)\). ANSYS Fluent will automatically account for the refractive index in setting band limits for media with \( n \) different from unity.

**Figure 13.17: The Radiation Model Dialog Box (Non-Gray DO Model)**

![Radiation Model Dialog Box (Non-Gray DO Model)](image)

The frequency of radiation remains constant as radiation travels across a semi-transparent interface. The wavelength, however, changes such that \( n\lambda \) is constant. Therefore, when radiation passes from a medium with refractive index \( n_1 \) to one with refractive index \( n_2 \), the following relationship holds:

\[
n_1 \lambda_1 = n_2 \lambda_2
\]

(13.7)

Here \( \lambda_1 \) and \( \lambda_2 \) are the wavelengths associated with the two media. It is conventional to specify the wavelength rather than frequency. ANSYS Fluent requires you to specify wavelength bands (in \( \mu \text{m} \)) for an equivalent medium with \( n = 1 \).

For example, consider a typical glass with a step jump in the absorption coefficient at a cut-off wavelength of \( \lambda_c \). The absorption coefficient is \( a_1 \) for \( \lambda \leq \lambda_c \) and \( a_2 \) for \( \lambda > \lambda_c \). The refractive index of the glass is \( n_g \). Since \( n\lambda \) is constant across a semi-transparent interface, the equivalent cut-off wavelength for a medium with \( n = 1 \) is \( n_g \lambda_c \) using Equation 13.7 (p. 796). You should choose two bands in this case, with...
the limits 0 to \( n_{gC} \) and \( n_{gC} \) to 100. Here, the upper wavelength limit has been chosen to be a large number, 100, in order to ensure that the entire spectrum is covered by the bands. When multiple materials exist, you should convert all the cut-off wavelengths to equivalent cut-off wavelengths for an \( n = 1 \) medium, and choose the band boundaries accordingly.

The bands can have different widths and need not be contiguous. You can ensure that the entire spectrum is covered by your bands by choosing \( \lambda_{\text{min}} = 0 \) and \( n\lambda_{\text{max}} T_{\text{min}} \geq 50,000 \). Here \( \lambda_{\text{min}} \) and \( \lambda_{\text{max}} \) are the minimum and maximum wavelength bounds of your wavelength bands, and \( T_{\text{min}} \) is the minimum expected temperature in the domain.

ANSYS Fluent allows you to use a user-defined function (UDF) to modify the emissivity weighting factor \( F(0 \rightarrow n\lambda_{2}T) - F(0 \rightarrow n\lambda_{1}T) \) (which otherwise defaults to the black body emission factor obtained from a standard Planck distribution). The emissivity weighting factor appears in the emission term of the radiative transfer equation for the non-gray model, as shown in Equation 5.61 in the Theory Guide. For more information, see \texttt{DEFINE_EMISSIVITY_WEIGHTING_FACTOR} in the UDF Manual.

### 13.3.5.3. Enabling DO/Energy Coupling

For applications involving optical thicknesses greater than 10, you can enable the \textbf{DO/Energy Coupling} option in the \textbf{Radiation Model} (Figure 13.18: The Radiation Model Dialog Box with DO/Energy Coupling Enabled (p. 797)) in order to couple the energy and intensity equations at each cell, solving them simultaneously. This approach accelerates the convergence of the finite volume scheme for radiative heat transfer and can be used with the gray or non-gray radiation model.

**Figure 13.18: The Radiation Model Dialog Box with DO/Energy Coupling Enabled**
13.3.6. Defining Material Properties for Radiation

When you are using the P-1, DO, or Rosseland radiation model in ANSYS Fluent, you should be sure to define both the absorption and scattering coefficients of the fluid in the Create/Edit Materials dialog box. Note that you can either enter a constant value for these parameters, or you can specify them using a user-defined function (UDF). For more information, see DEFINEPROPERTY UDFs in the UDF Manual.

Materials

If you are modeling semi-transparent media using the DO model, you should also define the refractive index for the semi-transparent fluid or solid material. When using the Rosseland model, you can specify the refractive index only for the fluid material. When using the P-1 model, you should define the refractive index for the fluid material only. For the DTRM, you need to define only the absorption coefficient.

If your model includes gas phase species such as combustion products, absorption and/or scattering in the gas may be significant. The scattering coefficient should be increased from the default of zero if the fluid contains dispersed particles or droplets that contribute to scattering. Alternatively, you can specify the scattering coefficient as a user-defined function (UDF). For more information, see DEFINEPROPERTY UDFs in the UDF Manual.

ANSYS Fluent allows you to input a composition-dependent absorption coefficient for CO₂ and H₂O mixtures, using the WSGGM. The method for computing a variable absorption coefficient is described in Radiation in Combusting Flows in the Theory Guide. Radiation Properties (p. 451) provides a detailed description of the procedures used for input of radiation properties.

13.3.6.1. Absorption Coefficient for a Non-Gray Model

If you are using the non-gray P-1 model or non-gray DO model, you can specify a different constant absorption coefficient for each of the bands used by the gray-band model, as described in Radiation Properties (p. 451). You cannot, however, compute a composition-dependent absorption coefficient in each band. If you use the WSGGM to compute a variable absorption coefficient, the value will be the same for all bands. Alternatively, you can specify a user-defined function (UDF) for the absorption coefficient. For more information, see DEFINEPROPERTY UDFs in the UDF Manual.

13.3.6.2. Refractive Index for a Non-Gray Model

If you are using the non-gray P-1 model or non-gray DO model, you can specify a different constant refractive index for each of the bands used by the gray-band model, as described in Radiation Properties (p. 451). You cannot, however, compute a composition-dependent refractive index in each band.

13.3.7. Defining Boundary Conditions for Radiation

When you set up a problem that includes radiation, you will set additional boundary conditions at inlets, exits, and walls. These inputs are described below.
13.3.7.1. Inlet and Exit Boundary Conditions

13.3.7.1.1. Emissivity

When radiation is active, you can define the emissivity at each inlet and exit boundary when you are defining boundary conditions in the associated inlet or exit boundary dialog box (Pressure Inlet dialog box, Velocity Inlet dialog box, Pressure Outlet dialog box, etc.). Enter the appropriate value for Internal Emissivity. The default value for all boundary types is 1. Alternatively, you can specify a user-defined function for emissivity. For more information, see DEFINE_PROFILE in the UDF Manual.

For the non-gray P-1 model and the non-gray DO model, the specified constant emissivity will be used for all wavelength bands.

**Important**

The Internal Emissivity boundary condition is not available with the Rosseland model.

13.3.7.1.2. Black Body Temperature

ANSYS Fluent includes an option that allows you to take into account the influence of the temperature of the gas and the walls beyond the inlet/exit boundaries, and specify different temperatures for radiation and convection at inlets and exits. This is useful when the temperature outside the inlet or exit differs considerably from the temperature in the enclosure. For example, if the temperature of the walls beyond the inlet is 2000 K and the temperature at the inlet is 1000 K, you can specify the outside wall temperature to be used for computing radiative heat flux, while the actual temperature at the inlet is used for calculating convective heat transfer. To do this, you would specify a radiation temperature of 2000 K as the black body temperature.

Although this option allows you to account for both cooler and hotter outside walls, you must use caution in the case of cooler walls, since the radiation from the immediate vicinity of the hotter inlet or outlet almost always dominates over the radiation from cooler outside walls. If, for example, the temperature of the outside walls is 250 K and the inlet temperature is 1500 K, it might be misleading to use 250 K for the radiation boundary temperature. This temperature might be expected to be somewhere between 250 K and 1500 K; in most cases it will be close to 1500 K. Its value depends on the geometry of the outside walls and the optical thickness of the gas in the vicinity of the inlet.

In the flow inlet or exit dialog box (Pressure Inlet dialog box, Velocity Inlet dialog box, etc.), select Specified External Temperature in the External Black Body Temperature Method drop-down list, and then enter the value of the radiation boundary temperature as the Black Body Temperature.

**Important**

- If you want to use the same temperature for radiation and convection, retain the default selection of Boundary Temperature as the External Black Body Temperature Method.
- The Black Body Temperature boundary condition is not available with the Rosseland model.
13.3.7.2. Wall Boundary Conditions for the DTRM, and the P-1, S2S, and Rosseland Models

The DTRM and the S2S, Rosseland, and gray P-1 (that is, **Number of Bands** is set to zero) models assume all walls to be gray and diffuse. The only radiation boundary condition required in the **Wall** dialog box is the emissivity. For the Rosseland model, the internal emissivity is 1. For the DTRM and the S2S and gray P-1 models, you can enter the appropriate value for **Internal Emissivity** in the **Thermal** tab of the **Wall** dialog box. The default value is 1. Alternatively, you can specify a user-defined function for emissivity. For more information, see DEFINE_PROFILE in the UDF Manual.

For the non-gray P–1 model, specify a constant **Internal Emissivity** for each wavelength band in the **Radiation** tab of the **Wall** dialog box (the default value in each band is 1). Alternatively, you can specify the internal emissivity using a boundary condition parameter (see Creating a New Parameter (p. 209)). See Defining Boundary Conditions for Radiation (p. 798) for details.

### 13.3.7.2.1. Boundary Conditions for the S2S Model

When the S2S model is used, you can specify that some of the walls and inlet and exit boundaries are not participating in the view factor calculation. This capability allows you to save time computing the view factors and also reduce the memory required to store the view factor file during the ANSYS Fluent calculation. See Specifying Boundary Zone Participation (p. 789) for details.

**Important**

- Whenever you revise which the boundary zones participate in the calculation, you will need to recompute the view factors.

- The **Flux Reports** dialog box will not show the exact balance of the Radiation Heat Transfer Rate because the radiative heat transfer to those boundaries that do not participate in the view factor calculation is not included.

### 13.3.7.3. Wall Boundary Conditions for the DO Model

When the DO model is used, you can model opaque walls, as discussed in Boundary and Cell Zone Condition Treatment at Opaque Walls in the Theory Guide, as well as semi-transparent walls (Cell Zone and Boundary Condition Treatment at Semi-Transparent Walls in the Theory Guide).

You can use a diffuse wall to model wall boundaries in many industrial applications since, for the most part, surface roughness makes the reflection of incident radiation diffuse. For highly polished surfaces, such as reflectors or mirrors, the specular boundary condition is appropriate. The semi-transparent boundary condition can be appropriate, for example, when modeling for glass panes in air.

#### 13.3.7.3.1. Opaque Walls

In the **Radiation** tab of the **Wall** dialog box (Figure 13.19: The Wall Dialog Box Showing Radiation Conditions for an Opaque Wall (p. 801)), select **opaque** in the **BC Type** drop-down list to specify an opaque wall. Opaque walls are treated as gray if gray radiation is being computed, or non-gray if the non-gray DO model is being used. If the non-gray DO model is being used, the **Diffuse Fraction** can be specified for each band.
After you have selected **opaque** as the **BC Type**, you can specify the fraction of reflected radiation flux that is to be treated as diffuse. By default, the **Diffuse Fraction** is set to 1, indicating that all of the radiation is diffuse. A diffuse fraction equal to 0 indicates purely specular reflected radiation. A diffuse fraction between 0 and 1 will result in partially diffuse and partially specular reflected energy. See **Boundary and Cell Zone Condition Treatment at Opaque Walls** in the Theory Guide for more details.

You will also be required to specify the internal emissivity in the **Thermal** tab of the **Wall** dialog box (Figure 13.20: The Wall Dialog Box Showing Internal Emissivity Thermal Conditions for an Opaque Wall (p. 802)). For gray-radiation DO models, enter the appropriate value for **Internal Emissivity**. (The default value is 1.) The value that you specify will be applied to the diffuse component only. For non-gray DO models, specify a constant **Internal Emissivity** for each wavelength band in the **Radiation** tab of the **Wall** dialog box. (The default value in each band is 1.) Alternatively, you can specify the internal emissivity using a boundary condition parameter (see Creating a New Parameter (p. 209)).
You can also specify the external emissivity and external radiation temperature for an opaque wall when the thermal conditions are set to **Radiation** or **Mixed** in the **Wall** dialog box (Figure 13.21: The Wall Dialog Box Showing External Emissivity and External Radiation Temperature Thermal Conditions (p. 803)). Alternatively, you can specify a UDF for these parameters; for more information, see **DEFINE_PROFILE** in the **UDF Manual**.
For more information on boundary condition treatment at opaque walls, see Boundary and Cell Zone Condition Treatment at Opaque Walls in the Theory Guide.

### 13.3.7.3.2. Semi-Transparent Walls

To define radiation for an exterior semi-transparent wall, click the **Radiation** tab in the **Wall** dialog box and then select **semi-transparent** in the **BC Type** drop-down list (Figure 13.22: The Wall Dialog Box for a Semi-Transparent Wall Boundary (p. 804)). The dialog box will expand to display the semi-transparent wall inputs needed to define an external irradiation flux (Figure 13.22: The Wall Dialog Box for a Semi-Transparent Wall Boundary (p. 804)).
Then perform the following steps:

1. Specify the value of the irradiation flux (in W/m$^2$) under Direct or Diffuse Irradiation. If the non-gray DO model is being used, a constant Direct or Diffuse Irradiation can be specified for each band.

   **Important**

   Note that the external diffuse irradiation specified when using Radiation or Mixed thermal conditions (selected in the Thermal tab), or Diffuse Irradiation (in the Radiation tab) is always distributed hemispherically after transmission through semi-transparent walls (that is independent of whether the external semi-transparent boundary wall is defined as a diffusely or specularly reflecting type).

2. **Apply Direct Irradiation Parallel to the Beam** is the default means of specifying the scale of irradiation flux. When enabled, ANSYS Fluent assumes that the value of Direct Irradiation that you specify is the irradiation flux parallel to the Beam Direction. When deselected, ANSYS Fluent instead assumes that the value specified is the flux parallel to the face normals and will calculate the resulting beam parallel flux.
for every face. See Figure 5.12: DO Irradiation on External Semi-Transparent Wall in Semi-Transparent Exterior Walls in the Theory Guide for details.

3. Define the **Beam Width** by specifying the beam **Theta** and **Phi** extents. Beam width is specified as the solid angle over which the irradiation is distributed. The default value for beam width is $10^{-6}$, which is suitable for collimated beam radiation. A beam width less than this is likely to result in zero irradiation flux.

4. Specify the $(X,Y,Z)$ vector that defines the **Beam Direction**. The beam direction is defined as the vector of the centroid of the solid angle (beam width). You can specify the **Beam Direction** as a constant, a profile or a UDF. This is especially useful in applications where the shape of the radiative source is circular or cylindrical (or non-linear). For information about boundary profiles, see Reading and Writing Profile Files (p. 54).

Note that the actual direction of the beam of radiation that enters the domain will be further influenced by the solid angles available from the number of divisions set up; the effective direction will be the direction vector of the solid angle that the incoming beam falls into. Finally, any non-zero diffuse fraction will act to spread out (hemispherically, proportional to the diffuse fraction) the irradiation that enters the domain.

For a UDF example that specifies the beam direction, see Example 5 - Beam Direction Profile at Semi-Transparent Walls in the UDF Manual.

5. Specify the fraction of the irradiation that is to be treated as diffuse as a real number between 0 and 1. By default, the **Diffuse Fraction** is set to 1, indicating that all of the irradiation is diffuse. A diffuse fraction of 0 treats the radiation as purely specular. If you specify a value between 0 and 1, the radiation is treated as partially diffuse and partially specular. If the non-gray DO model is being used, the **Diffuse Fraction** can be specified for each band. See Diffuse Semi-Transparent Walls in the Theory Guide for details.

**Important**

- Note that the refractive index of the external medium is assumed to be 1.

- If **Heat Flux** conditions are specified in the **Thermal** tab of the **Wall** dialog box, the specified heat flux is considered to be only the conduction and convection portion of the boundary flux. The given irradiation specifies the incoming exterior radiative flux; the radiative flux transmitted from the domain interior to the outside is computed as a part of the calculation by ANSYS Fluent. Internal emissivity is ignored for semi-transparent surfaces.

- Note that when a boundary wall is made semi-transparent ANSYS Fluent calculates the amount of radiation leaving as well as entering the domain. If you do not provide a source of irradiation or a radiating thermal condition (for example **Mixed** or **Radiation**) then you are effectively radiating to a temperature of 0 K and it is highly likely you may observe temperatures in your model that are lower than expected. Ensure that the external (incoming) radiant conditions give good account of the surroundings.

You can also specify the external emissivity and external radiation temperature for a semi-transparent wall when the thermal conditions are set to **Radiation** or **Mixed** in the **Wall** dialog box (Figure 13.21: The Wall Dialog Box Showing External Emissivity and External Radiation Temperature Thermal Conditions (p. 803)). Alternatively, you can specify a user-defined function (UDF) for these parameters; for more information, see DEFINE_PROFILE in the UDF Manual.
For a detailed description of boundary condition treatment at semi-transparent walls, see Cell Zone and Boundary Condition Treatment at Semi-Transparent Walls in the Theory Guide.

To define radiation for an interior (two-sided) semi-transparent wall, in the Wall dialog box click the Radiation tab and then select semi-transparent in the BC Type drop-down list (Figure 13.23: The Wall Dialog Box for an Interior Semi-Transparent Wall (p. 806)). Then specify the Diffuse Fraction as described for the previous case.

---

**Important**

Note that for semi-transparent walls, the internal emissivity defined under thermal conditions is ignored. If you want to include the effect of internal emissivity at semi-transparent walls, you must create a solid zone and specify that it participates in the radiation calculation; see Solid Semi-Transparent Media in the Theory Guide for details.

---

**Figure 13.23: The Wall Dialog Box for an Interior Semi-Transparent Wall**

![Wall Dialog Box](image)

---

**13.3.7.4. Solid Cell Zones Conditions for the DO Model**

With the DO model, you can specify whether or not you want to solve for radiation in each cell zone in the domain. By default, the DO equations are solved in all fluid zones, but not in any solid zones. If you want to model semi-transparent media, for example, you can enable radiation in the solid zone(s).
To do so, enable the **Participates In Radiation** option in the **Solid** dialog box (Figure 13.24: The Solid Dialog Box (p. 807)).

**Figure 13.24: The Solid Dialog Box**

![Solid Dialog Box](image)

---

**Important**

In general, you should *not* disable the **Participates In Radiation** option for any fluid zones.

See **Solid Semi-Transparent Media** in the Theory Guide for more information on solid semi-transparent media.

### 13.3.7.5. Thermal Boundary Conditions

In general, any well-posed combination of thermal boundary conditions can be used when any of the radiation models is active. The radiation model will be well-posed in combination with fixed temperature walls, conducting walls, and/or walls with set external heat transfer boundary conditions (Thermal Boundary Conditions at Walls (p. 318)). You can also use any of the radiation models with heat flux boundary conditions defined at walls, in which case the heat flux you define will be treated as the sum of the convective and radiative heat fluxes. The exception to this is the case of semi-transparent walls for the DO model. Here, ANSYS Fluent allows you to specify the convective and radiative portions of the heat flux separately.

### 13.3.8. Solution Strategies for Radiation Modeling

For the P-1, DTRM, S2S, and the DO radiation models, there are several parameters that control the radiation calculation. You can use the default solution parameters for most problems, or you can modify...
these parameters to control the convergence and accuracy of the solution. Iteration parameters that are unique for a particular radiation model are specified in the Radiation Model dialog box (for example, Energy Iterations per Radiation Iteration). Spatial Discretization (Discretization in the Theory Guide) and Under-Relaxation (Under-Relaxation of Variables in the Theory Guide) are specified in the Solution Methods and Solution Controls task pages, respectively. The Convergence Criterion (Modifying Convergence Criteria (p. 1484)) is set in the Residual Monitors dialog box.

There are no solution parameters to be set for the Rosseland model, since it impacts the solution only through the energy equation.

**Important**

If radiation is the only model being solved in ANSYS Fluent, and all other equations are switched off, then the Energy Iterations per Radiation Iteration solution parameter that is available for certain radiation models is automatically reset to 1.

### 13.3.8.1. P-1 Model Solution Parameters

For the P-1 radiation model, you can control the convergence criterion and under-relaxation factor. You should also pay attention to the optical thickness, as described below.

The default convergence criterion for the P-1 model is $10^{-6}$, the same as that for the energy equation, since the two are closely linked. See Monitoring Residuals (p. 1478) for details about convergence criteria. You can set the Convergence Criterion for $p1$ in the Residual Monitors dialog box.

Monitors → Residuals → Edit...

The under-relaxation factor for the P-1 model is set with those for other variables, as described in Setting Under-Relaxation Factors (p. 1418). Note that since the equation for the radiation temperature (Equation 5.21 in the Theory Guide) is a relatively stable scalar transport equation, in most cases you can safely use large values of under-relaxation (0.9–1.0).

For optimal convergence with the P-1 model, the optical thickness $(a + \sigma_s)L$ must be between 0.01 and 10 (preferably not larger than 5). Smaller optical thicknesses are typical for very small enclosures (characteristic size of the order of 1 cm), but for such problems you can safely increase the absorption coefficient to a value for which $(a + \sigma_s)L = 0.01$. Increasing the absorption coefficient will not change the physics of the problem because the difference in the level of transparency of a medium with optical thickness $= 0.01$ and one with optical thickness <0.01 is indistinguishable within the accuracy level of the computation.

### 13.3.8.2. DTRM Solution Parameters

When the DTRM is active, ANSYS Fluent updates the radiation field during the calculation and computes the resulting energy sources and heat fluxes via the ray-tracing technique described in Ray Tracing in the Theory Guide. ANSYS Fluent provides several solution parameters in the expanded portion of the Radiation Model dialog box (Figure 13.25: The Radiation Model Dialog Box (DTRM) (p. 809)).
Figure 13.25: The Radiation Model Dialog Box (DTRM)

You can control the maximum number of iterations of the radiation calculation during each global iteration by changing the Maximum Number of Radiation Iterations. The default setting of 5 means that the radiosity will be updated up to 5 times. The actual number of iterations will be less if the residual convergence criterion is exceeded at any point during these iterations.

The Residual Convergence Criteria parameter (0.001 by default) determines when the radiation intensity update is converged. It is defined as the maximum normalized change in the surface intensity from one DTRM radiation iteration to the next (see Equation 13.8 (p. 811)).

You can also control the frequency that the radiation field is updated as the continuous-phase solution proceeds. The Energy Iterations per Radiation Iteration parameter is set to 10 by default. This means that the radiation calculation is performed once every 10 iterations of the solution process. Increasing the number can speed the calculation process, but may slow overall convergence.

13.3.8.3. S2S Solution Parameters

For the S2S model, as for the DTRM, you can control the frequency with which the radiosity is updated as the continuous-phase solution proceeds. See the previous description of Energy Iterations per Radiation Iteration.

If you are using the pressure-based solver and you first solve the flow equations with the energy equation turned off, you should reduce the Energy Iterations per Radiation Iteration from 10 to 1.
or 2. This will ensure the convergence of the radiosity. If the default value of 10 is kept in this case, it is possible that the flow and energy residuals may converge and the solution will terminate before the radiosity is converged. See Residual Reporting for the S2S Model (p. 811) for more information about residuals for the S2S model.

You can control the maximum number of iterations of the radiation calculation during each global iteration by changing the **Maximum Number of Radiation Iterations**. The default setting of 5 means that the radiosity will be updated up to 5 times. The actual number of iterations will be less if the residual convergence criterion is exceeded at any point during these iterations.

The **Residual Convergence Criteria** (0.001 by default) determines when the radiosity update is converged. It is defined as the maximum normalized change in the radiosity from one S2S radiation iteration to the next (see Equation 13.9 (p. 811)).

### 13.3.8.4. DO Solution Parameters

For the discrete ordinates model, as for the DTRM, you can control the frequency that the surface intensity is updated as the continuous phase solution proceeds. See the description of **Energy Iterations per Radiation Iteration** for the DTRM, as mentioned in the previous sections.

For most problems, the default under-relaxation of 1.0 for the DO equations is adequate. For problems with large optical thicknesses ($\alpha L > 10$), you may experience slow convergence or solution oscillation. For such cases, under-relaxing the energy and DO equations is useful. Under-relaxation factors between 0.9 and 1.0 are recommended for both equations.

### 13.3.8.5. Running the Calculation

Once the radiation problem has been set up, you can proceed as usual with the calculation. Note that while the P-1 and DO models will solve additional transport equations and report residuals, the DTRM and the Rosseland and S2S models will not (since they impact the solution only through the energy equation). Residuals for the DTRM and S2S model radiation iterations are reported by ANSYS Fluent every time such an iteration is performed, as described below.

#### 13.3.8.5.1. Residual Reporting for the P-1 Model

The residual for radiation as calculated by the P-1 model is updated after each iteration and reported with the residuals for all other variables. ANSYS Fluent reports the normalized P-1 radiation residual as defined in Monitoring Residuals (p. 1478) for the other transport equations.

#### 13.3.8.5.2. Residual Reporting for the DO Model

After each DO iteration, the DO model reports a composite normalized residual for all the DO transport equations. The definition of the residuals is similar to that for the other transport equations (see Monitoring Residuals (p. 1478)).

#### 13.3.8.5.3. Residual Reporting for the DTRM

ANSYS Fluent does not include a DTRM residual in its usual residual report that is issued after each iteration. The effect of radiation on the solution can be gathered, instead, via its impact on the energy field and the energy residual. However, each time a DTRM iteration is performed, ANSYS Fluent will print out the normalized radiation error for each DTRM radiation iteration. The normalized radiation error is defined as
\[ E = \frac{\sum_{\text{all radiating surfaces}} (I_{\text{new}} - I_{\text{old}})}{N \left( \frac{\sigma T^4}{\pi} \right)} \]  

(13.8)

where the error \( E \) is the maximum change in the intensity (\( I \)) at the current radiation iteration, normalized by the maximum surface emissive power, and \( N \) is the total number of radiating surfaces. Note that the default radiation convergence criterion, as noted in DTRM Solution Parameters (p. 808), defines the radiation calculation to be converged when \( E \) decreases to \( 10^{-3} \) or less.

### 13.3.8.5.4. Residual Reporting for the S2S Model

ANSYS Fluent does not include an S2S residual in its usual residual report that is issued after each iteration. The effect of radiation on the solution can be gathered, instead, via its impact on the energy field and the energy residual. However, each time an S2S iteration is performed, ANSYS Fluent will print out the normalized radiation error for each S2S radiation iteration. The normalized radiation error is defined as

\[ E = \frac{\sum_{\text{all radiating surface clusters}} (J_{\text{new}} - J_{\text{old}})}{N_0 \sigma T^4} \]  

(13.9)

where the error \( E \) is the maximum change in the radiosity (\( J \)) at the current radiation iteration, normalized by the maximum surface emissive power, and \( N_0 \) is the total number of radiating surface clusters. Note that the default radiation convergence criterion, as noted in DTRM Solution Parameters (p. 808), defines the radiation calculation to be converged when \( E \) decreases to \( 10^{-3} \) or less.

### 13.3.8.5.5. Disabling the Update of the Radiation Fluxes

Sometimes, you may want to set up your ANSYS Fluent model with the radiation model active and then disable the radiation calculation during the initial calculation phase. For the P-1 and DO models, you can turn off the radiation calculation temporarily by deselecting \textit{P1} or \textit{Discrete Ordinates} in the \textit{Equations} list, which is accessed via the \textit{Solution Controls} task page. For the DTRM and the S2S model, there is no item in the \textit{Equations}. You can instead set a very large number for \textit{Energy Iterations per Radiation Iteration} in the \textit{Iteration Parameters} group box of the \textit{Radiation Model} dialog box.

If you turn off the radiation calculation, ANSYS Fluent will skip the update of the radiation field during subsequent iterations, but will leave in place the influence of the current radiation field on energy sources due to absorption, wall heat fluxes, etc. Turning the radiation calculation off in this way can therefore be used to initiate your modeling work with the radiation model inactive and/or to focus the computational effort on the other equations if the radiation model is relatively well converged.

### 13.3.9. Postprocessing Radiation Quantities

Information regarding postprocessing radiation quantities can be found in the following sections:

13.3.9.1. Available Variables for Postprocessing
13.3.9.2. Reporting Radiative Heat Transfer Through Boundaries
13.3.9.3. Overall Heat Balances When Using the DTRM
13.3.9.4. Displaying Rays and Clusters for the DTRM
13.3.9.5. Reporting Radiation in the S2S Model
13.3.9.1. Available Variables for Postprocessing

ANSYS Fluent provides radiation quantities that you can use in postprocessing when your model includes the solution of radiative heat transfer. You can generate graphical plots or alphanumeric reports of the following variables/functions:

In the **Radiation...** category:

- **Incident Radiation** (P-1 and DO models)
- **Incident Radiation (Band n)** (non-gray P-1 and non-gray DO models)
- **Absorption Coefficient** (DTRM, P-1, DO, and Rosseland models)
- **Scattering Coefficient** (P-1, DO, and Rosseland models)
- **Refractive Index** (P–1, DO, and Rosseland models)
- **Radiation Temperature** (P-1 and DO models)
- **Surface Cluster ID** (S2S model)

In the **Wall Fluxes...** category:

- **Radiation Heat Flux** (all radiation models)
- **Surface Incident Radiation** (S2S, DTRM, and DO models)
- **Absorbed Radiation Flux** (DO model, semi-transparent wall)
- **Reflected Radiation Flux** (DO model, semi-transparent wall)
- **Transmitted Radiation Flux** (DO model, semi-transparent wall)
- **Beam Irradiation Flux** (DO model, semi-transparent wall)

See [Field Function Definitions](p. 1765) for definitions of these postprocessing variables. Note that in addition, incident radiation, transmitted, reflected and absorbed radiation flux are also available on a per-band basis for the non-gray DO model.

---

**Important**

- The sign convention on the radiative heat flux is such that the heat flux from the wall surface is a positive quantity.

- It is possible to export heat flux data on wall zones (including radiation) to a generic file that you can examine or use in an external program. See [Exporting Heat Flux Data](p. 765) for details.

- Take care not to confuse **Incident Radiation** and **Surface Incident Radiation**. **Incident Radiation** is a volumetric quantity giving the total radiant load passing through the cell (in all directions), whereas **Surface Incident Radiation** is the total radiant load hitting the surface (which will subsequently be absorbed, transmitted and reflected). There is no direct means to report how much radiation has been absorbed/emitted/scattered in cells.
13.3.9.2. Reporting Radiative Heat Transfer Through Boundaries

You can use the Flux Reports dialog box to compute the radiative heat transfer through each boundary of the domain, or to sum the radiative heat transfer through all boundaries.

 Flux Reports → Fluxes → Set Up...

See Fluxes Through Boundaries (p. 1746) for details about generating flux reports.

13.3.9.3. Overall Heat Balances When Using the DTRM

The DTRM yields a global heat balance and a balance of radiant heat fluxes only in the limit of a sufficient number of rays. In any given calculation, therefore, if the number of rays is insufficient you may find that the radiant fluxes do not obey a strict balance. Such imbalances are the inevitable consequence of the discrete ray tracing procedure and can be minimized by selecting a larger number of rays from each wall boundary.

13.3.9.4. Displaying Rays and Clusters for the DTRM

When you use the DTRM, ANSYS Fluent allows you to display surface or volume clusters, as well as the rays that emanate from a particular surface cluster. You can use the DTRM Graphics dialog box (Figure 13.26: The DTRM Graphics Dialog Box (p. 813)) for all of these displays.

Display → DTRM Graphics...

Figure 13.26: The DTRM Graphics Dialog Box

13.3.9.4.1. Displaying Clusters

To view clusters, select Cluster under Display Type and then select either Surface or Volume under Cluster Type.
To display all of the surface or volume clusters, select the **Display All Clusters** option under **Cluster Selection** and click the **Display** button.

To display only the cluster (surface or volume) nearest to a specified point, deselect the **Display All Clusters** option and specify the coordinates under **Nearest Point**. You may also use the mouse to choose the nearest point. Click the **Select Point With Mouse** button and then right-click a point in the graphics window.

### 13.3.9.4.2. Displaying Rays

To display the rays emanating from the surface cluster nearest to the specified point, select **Ray** under **Display Type**. Set the appropriate values for **Theta** and **Phi Divisions** under **Ray Parameters** (see Setting Up the DTRM (p. 780) for details), and then click the **Display** button. Figure 13.27: Ray Display (p. 814) shows a ray plot for a simple 2D geometry.

**Figure 13.27: Ray Display**

---

### 13.3.9.4.3. Including the Mesh in the Display

For some problems, especially complex 3D geometries, you may want to include portions of the mesh in your ray or cluster display as spatial reference points. For example, you may want to show the location of an inlet and an outlet along with displaying the rays. This is accomplished by enabling the **Draw Mesh** option in the **DTRM Graphics** dialog box. The **Mesh Display** dialog box will appear automatically when you enable the **Draw Mesh** option, and you can set the mesh display parameters there. When you click **Display** in the **DTRM Graphics** dialog box, the mesh display, as defined in the **Mesh Display** dialog box, will be included in the ray or cluster display.

### 13.3.9.5. Reporting Radiation in the S2S Model

When you use the S2S model, ANSYS Fluent allows you to view the values of the view factor and radiation emitted from one zone to any other zone. You can use the **S2S Information** dialog box (Figure 13.28: The
**S2S Information Dialog Box (p. 815)** to generate a report of these values in the console or as a separate file.

**Report → S2S Information...**

**Figure 13.28: The S2S Information Dialog Box**

The steps for generating the report are as follows:

1. Specify the values in which you are interested by selecting **View Factors** and/or **Incident Radiation**.

2. Choose the zones for which you would like data by selecting them in the lists under **From** and **To** (at least one zone must be selected under each list). To select all of the zones of a particular type, click that category in the list under **Boundary Types**.

3. Specify how you would like to present the data. To report the values in the console, click the **Compute** button. To write the data as an S2S Info File (.sif format), click the **Write...** button and enter a file name in **The Select File Dialog Box (p. 15)**.

The following is an example of how the data is presented:

```
S2S Information
From wall1 to:
  View factor   Incident Radiation
  wall1         0.0000       0.0000
  wall2         0.2929       171387.7813
  wall3         0.2929       155305.7969
  wall4         0.4142       29055.9023

From wall2 to:
  View factor   Incident Radiation
  wall1         0.2929       306451.9688
  wall2         0.0000       0.0000
  wall3         0.4142       214195.0938
  wall4         0.2929       19153.2715
```

Note that the header listed above (**S2S Information**) is not displayed in the console.
13.3.10. Solar Load Model

ANSYS Fluent provides a solar load model that can be used to calculate radiation effects from the sun’s rays that enter a computational domain. Two options are available for the model: solar ray tracing and DO irradiation. The ray tracing approach is a highly efficient and practical means of applying solar loads as heat sources in the energy equations. In cases where you want to use the discrete ordinates (DO) model to calculate radiation effects within the domain, an option is available to supply outside beam direction and intensity parameters directly to the DO model. The solar load model includes a solar calculator utility that can be used to construct the sun’s location in the sky for a given time-of-day, date, and position. Solar load is available in the 3D solver only, and can be used to model steady and unsteady flows.

13.3.10.1. Introduction

Typical applications that are well-suited for solar load simulations include the following:

- automotive climate control (ACC) applications
- human comfort modeling applications in buildings

The effects of solar loading are needed in many ACC applications, where the temperature, humidity, and velocity fields around passengers (and drivers) are desired. ACC systems are tested for their capacity to cool down passenger compartments after they have been “soaked” in intense solar radiation. ANSYS Fluent’s solar load model will enable you to simulate solar loading effects and predict the time it will take to reasonably cool down the cabin of a car that has been exposed to solar radiation, as well as predict the time interval needed to lower the temperature in specified points and areas within the domain.

In the analysis of buildings, solar loading provides a significant burden on the cooling requirement in warm climates, particularly where architects want to use the aesthetics of glazed facades. Even in cooler climates, solar loading can provide a burden during warmer seasons where modern buildings are well insulated against thermal loss during winter months. As well as providing an engineer with a practical tool for determining the solar heating effect inside a building, ANSYS Fluent’s solar load model will allow the solar transmission through all glazed surfaces to be determined over the course of a day, allowing important decisions to be made before undertaking any flow studies. ANSYS Fluent’s solar load model also allows you to simulate porous blinds, which can transmit a portion of the solar radiation while also allowing fluid flow.

13.3.10.2. Solar Ray Tracing

The solar load model’s ray tracing algorithm can be used to predict the direct illumination energy source that results from incident solar radiation. It takes a beam that is modeled using the sun position vector and illumination parameters, applies it to any or all wall, porous jump, and inlet/outlet boundary zones that you specify, performs a face-by-face shading analysis to determine well-defined shadows on all boundary faces and interior walls, and computes the heat flux on the boundary faces that results from the incident radiation.

Important

The solar ray tracing model includes only boundary zones that are adjacent to fluid zones in the ray tracing calculation. In other words, boundary zones that are attached to solid zones are ignored.
The resulting heat flux that is computed by the solar ray tracing algorithm is coupled to the ANSYS Fluent calculation via a source term in the energy equation. The heat sources are added directly to computational cells bordering each face and are assigned to adjacent cells in the following order: shell conduction cells, solid cells, and fluid cells. Heat sources are assigned to one of these types of adjacent cells, only. You can choose to override this order and include adjacent fluid cells in the solar load calculation by issuing a command in the text user interface (see Text Interface-Only Commands (p. 836) for details). Note that the sun position vector and solar intensity can be entered either directly by you or computed from the solar calculator. Direct and diffuse irradiation parameters can also be specified using a user-defined function (UDF) and hooked to ANSYS Fluent in the Radiation Model dialog box.

The solar ray tracing option allows you to include the effects of direct solar illumination as well as diffuse solar radiation in your ANSYS Fluent model. A two-band spectral model is used for direct solar illumination and accounts for separate material properties in the visible and infrared bands. A single-band hemispherical-averaged spectral model is used for diffuse radiation. Opaque materials are characterized in terms of two-band absorptivities. A semi-transparent material requires specification of absorptivity and transmissivity. Values that you specify for transmissivity and absorptivity are defined for normal incident rays. ANSYS Fluent recomputes/interpolates these values for the given angle of incidence.

The solar ray tracing algorithm also accounts for internal scattered and diffusive loading. The reflected component of direct solar irradiation is tracked. A fraction of this radiative heat flux, called internally scattered energy, is applied to all the surfaces participating in the solar load calculation, weighted by area. The internally scattered energy depends on the scattering fraction that is specified in the TUI, whose default value is 1. Depending on the reflectivity of the primary surface, the scattering fraction can be responsible for the inclusion (or exclusion) of a large amount of radiation within the rest of the domain.

Also included as internally scattered energy is the contribution of the transmitted component of diffuse solar irradiation (which enters a domain through semi-transparent walls depending upon the hemispherical transmissivity). The total value of internally scattered energy is reported to the ANSYS Fluent console. The ambient flux is obtained by dividing the internally scattered energy by the total surface area of the faces participating in the solar load calculation.

Note that Solar Ray Tracing is not a participating radiation model. It does not deal with emission from surfaces, and the reflecting component of the primary incident load is distributed uniformly across all surfaces rather than being local to the surfaces reflected to. If surface emission is an important factor in your case then you can consider implementing a radiation model (for example, P-1) in conjunction with Solar Ray Tracing.

13.3.10.2.1. Shading Algorithm

The shading calculation that is used for solar ray tracing is a straightforward application of vector geometry. A ray is traced from the centroid of a test face in the direction of the sun. Every other face is checked to determine if the ray intersects the candidate face and if the candidate face is in front of the test face. If both conditions are met, then an opaque face completely shades the test face. A semi-transparent face attenuates the incident energy.

A Barycentric coordinate formulation is used to construct triangle-ray intersections. A quadrilateral ray intersection method is used to handle the case when model surfaces contain quadrilaterals. A quadtree preprocessing step is applied to reduce the ray tracing algorithm complexity that can lead to long runtime for $10^4$ faces and greater. The quad-tree refinement factor can be modified in the text interface. The default value of this parameter is 7, which is sufficient to cover the entire spectrum of mesh sizes between one cell and five million cells. If the mesh is greater than five million cells, an increase in this parameter would reduce the CPU time needed to compute the solar loads.
13.3.10.2.2. Glazing Materials

Incident solar radiation can be applied to glass and plastic glazing materials of various types at wall boundaries, and the effects of coated glazings modeled using the solar ray tracing algorithm. To model solar optical properties, you will need to specify the transmissivity and reflectivity of the material in the Wall boundary conditions dialog box. You can obtain these values from the glass (or plastic) manufacturer or use data from another source (for example, ASHRAE Handbook).

Glazing optical properties are dependent on incident angle, and the variation is significant for an incident angle greater than 40 degrees. As the incident angle increases from zero, transmissivity decreases, reflectivity increases, and absorptivity increases initially due to lengthened optical path, and then decreases as more incident radiation is reflected. The shape of the property curve varies with glass type and thickness. This difference is more pronounced for coated glass or for a multiple-pane glazing system. It cannot be assumed that all glazing systems have a universal angular dependence.

For coated glazings, the spectral transmissivity and reflectivity at any incident angle are approximated in the solar load model from the normal angle of incidence \( [26] (p. \, 2558) \).

Transmissivity is given by

\[
T(\theta, \lambda) = T(0, \lambda) T_{ref}(\theta)
\]

\[(13.10)\]

where

\[
T_{ref}(\theta) = a_0 + a_1 \cos(\theta) + a_2 \cos^2(\theta^2) + a_3 \cos^3(\theta^3) + a_4 \cos^4(\theta^4)
\]

\[(13.11)\]

Reflectivity is given by

\[
R(\theta, \lambda) = R(0, \lambda) [1 - R_{ref}(\theta)] + R_{ref}(\theta)
\]

\[(13.12)\]

where

\[
R_{ref}(\theta) = b_0 + b_1 \cos(\theta) + b_2 \cos^2(\theta^2) + b_3 \cos^3(\theta^3) + b_4 \cos^4(\theta^4) - T_{ref}(\theta)
\]

\[(13.13)\]

The constants used in Equation 13.10 (p. 818) and Equation 13.12 (p. 818) are for coated glazings and are taken from Finlayson and Arasteh. \([26] (p. \, 2558)\). The normal transmissivity and reflectivity, \(T(0, \lambda)\) and \(R(0, \lambda)\) are specified in the Wall boundary conditions dialog box.

13.3.10.2.3. Inputs

The following inputs are required for the solar ray tracing algorithm:

- sun direction vector
- direct solar irradiation
- diffuse solar irradiation
- spectral fraction
- direct and IR absorptivity (opaque wall)
- direct and IR absorptivity and transmissivity (semi-transparent wall and porous jump)
- diffuse hemispherical absorptivity and transmissivity (semi-transparent wall)
The sun direction vector is the direction vector looking to the sun, from which the direct irradiation will be incident. You can enter the vector components \((X, Y, Z)\) and the direct and diffuse solar irradiation fluxes in the **Radiation Model** dialog box, or you can have these parameters derived from the solar calculator. These irradiation fluxes can also be specified using a user-defined function (User-Defined Functions (UDFs) for Solar Load (p. 823)). The spectral fraction is the final input in the **Radiation Model** dialog box. This defines the split of visible and infra-red (shortwave and longwave respectively) radiation, specifically the fraction of the direct irradiation flux that is in the visible band. These quantities can also be defined through the text interface.

The scattering fraction defines the amount of non-absorbed radiation that will be distributed (uniformly) across all participating surfaces. This is required as the solar load model does not track the rays beyond the first opaque surface. Therefore, a highly glazed space where incident radiation is likely to be reflected back out will have a low value. Conversely, a predominantly opaque (wall-bounded) space where reflected radiation is likely to be incident upon (and ultimately absorbed by) other opaque surfaces will have a high value. This parameter is defined through the text interface only, taking a default value of 1.0:

\[
\text{define } \models \text{models } \rightarrow \text{radiation } \rightarrow \text{sol-} \text{ar-parameters } \rightarrow \text{scattering-fraction}
\]

The ground reflectivity is used by the solar calculator to compute the background diffuse radiation intensity component contributed to by radiation reflected off the ground. This should be based on typical figures for the surface reflectivity of the outside ground surfaces. By default this is set to 0.2, but can be adjusted through the text-interface:

\[
\text{define } \models \text{models } \rightarrow \text{radiation } \rightarrow \text{sol-} \text{ar-parameters } \rightarrow \text{ground-reflectivity}
\]

The quad-tree-refinement parameter determines the level of detail used by the shading algorithm. By default this is set to 7 which will generally work well, but can lie between 0 and 10. This is defined only through the text interface:

\[
\text{define } \models \text{models } \rightarrow \text{radiation } \rightarrow \text{sol-} \text{ar-parameters } \rightarrow \text{quad-tree-refinement}
\]

Further details on the text interface-only entries is provided later in this section (see Text Interface-Only Commands).

The absorptivity and transmissivity parameters related to a wall or porous jump are entered in the **Wall** (under the **Radiation** tab) or **Porous Jump** boundary condition dialog box, respectively, for the particular boundary zones you want to participate in solar ray tracing. On flow boundaries you have a solar transmissivity factor to allow you to attenuate the incoming solar flux, for example, set to 1 for a fully open inlet or set to 0 for a light obscuring louvered inlet.

### 13.3.10.3. DO Irradiation

The solar load model's discrete ordinates (DO) irradiation option provides you with an easy means of applying a solar load directly to the DO model. Unlike the ray tracing solar load option, the DO irradiation method does not compute heat fluxes and apply them as heat sources to the energy equation. Instead,
the irradiation flux is applied directly to semi-transparent walls (which you specify) as a boundary condition, and the radiative heat transfer is derived from the solution of the DO radiative transfer equation.

The following inputs are required for DO irradiation at semi-transparent walls:

- direct irradiation
- diffuse irradiation
- beam direction
- beam width
- diffuse fraction

In the Wall boundary condition dialog box for each semi-transparent wall you want to participate in DO irradiation, you can specify that the beam direction, direct irradiation, and diffuse irradiation be derived from the solar parameters (for example, solar calculator) that you set (or compute) in the Radiation Model dialog box. This is done by checking the Use Beam Direction from Solar Load Model Settings and Use Direct and Diffuse Irradiation from Solar Load Model Settings boxes. When selected, ANSYS Fluent sets the beam width (the angle subtended by the sun) to the default value of 0.53 degrees for DO irradiation.

**Important**

Note that the sign of the beam direction that is needed for the DO model is opposite the sun direction vector that is entered or derived from the solar parameters. The beam direction in the DO model is the direction of external radiation (for example, radiation coming from the sun), while the sun direction vector in the solar load model points to the sun. Incident radiation and the sun angle always have an opposite sign since they are quantities that are defined from opposite perspectives.

### 13.3.10.4. Solar Calculator

ANSYS Fluent provides a solar calculator that can be used to compute solar beam direction and irradiation for a given time, date, and position. These values can be used as inputs to the solar ray tracing algorithm or as semi-transparent wall boundary conditions for discrete ordinates (DO) irradiation.

#### 13.3.10.4.1. Inputs/Outputs

Inputs needed for the solar calculator are:

- global position (latitude, longitude, time zone)
- starting date and time
- mesh orientation
- solar irradiation method
- sunshine factor

Global position consists of latitude, longitude, and time zone (relative to GMT). The time of day for a transient simulation is the starting time plus the flow-time. For mesh orientation, you will need to specify
the North and East direction vector in the CFD mesh. The default solar irradiation method is Fair Weather Conditions. Alternatively, you can choose the Theoretical Maximum method. The sunshine factor is simply a linear reduction factor for the computed incident load that allows for cloud cover to be accounted for, if appropriate.

You can specify these inputs in the Solar Calculator dialog box that is accessible from the Radiation Model dialog box (Figure 13.32: The Solar Calculator Dialog Box (p. 827)). Alternatively, you can enter the parameters using text interface commands (Additional Text Interface Commands (p. 838)).

The following values are computed by the solar calculator and are displayed in the console whenever the solar calculator is used:

- sun direction vector
- sunshine fraction
- direct normal solar irradiation at earth's surface
- diffuse solar irradiation - vertical and horizontal surface
- ground reflected (diffuse) solar irradiation - vertical surface

Direct normal solar irradiation is computed using the ASHRAE Fair Weather Conditions method, when this option is selected in the solar calculator. Note: Equation 20 and Table 7 from Chapter 30 of the 2001 ASHRAE Handbook of Fundamentals. The theoretical maximum values for direct normal solar irradiation and diffuse solar irradiation are computed using NREL's Theoretical Maximum method, when this option is selected. In practice, these values are unlikely to be experienced due to atmospheric conditions.

ANSYS Fluent computes the diffuse solar irradiation components (vertical and horizontal) internally for each face in the domain. When the Theoretical Maximum method is chosen, these diffuse irradiation values provide estimates for the maximum vertical and horizontal surface effects.

13.3.10.4.2. Theory

ANSYS Fluent provides two options for computing the solar load: Fair Weather Conditions method and Theoretical Maximum method. Although these methods are similar, there is a key difference. The Fair Weather Conditions method imposes greater attenuation on the solar load, which is representative of atmospheric conditions that are fair—but not completely clear.

The equation for normal direct irradiation applying the Fair Weather Conditions Method is taken from the ASHRAE Handbook:

\[ E_{dn} = \frac{A}{B} \times \frac{1}{e \sin(\beta)} \]  \hspace{1cm} (13.14)

where \( A \) and \( B \) are apparent solar irradiation at air mass \( m=0 \) and atmospheric extinction coefficient, respectively. These values are based on the earth's surface on a clear day. \( \beta \) is the solar altitude (in degrees) above the horizontal.

The equation for direct normal irradiation that is used for the Theoretical Maximum Method is taken from NREL's Solar Position and Intensity Code (Solpos):

\[ E_{dn} = S_{etm} S_{unprime} \]  \hspace{1cm} (13.15)
where $S_{ctrn}$ is the top of the atmosphere direct normal solar irradiance and $S_{unprime}$ is the correction factor used to account for reduction in solar load through the atmosphere.

The calculation for the diffuse load in the solar model is based on the approach suggested in the 2001 ASHRAE Fundamental Handbook (Chapter 20, Fenestration). The equation for diffuse solar irradiation on a vertical surface is given by:

$$Ed = CYEdn$$  \hspace{1cm} (13.16)

where $C$ is a constant whose values are given in Table 7 from Chapter 30 of the 2001 ASHRAE Handbook of Fundamentals, $Y$ is the ratio of sky diffuse radiation on a vertical surface to that on a horizontal surface (calculated as a function of incident angle), and $Edn$ is the direct normal irradiation at the earth’s surface on a clear day.

The equation for diffuse solar irradiation for surfaces other than vertical surfaces is given by:

$$Ed = CEEdn \frac{(1 + \cos \varepsilon)}{2}$$  \hspace{1cm} (13.17)

where $\varepsilon$ is the tilt angle of the surface (in degrees) from the horizontal plane.

The equation for ground reflected solar irradiation on a surface is given by:

$$Er = Edn (C + \sin \beta) \rho_g \frac{(1 - \cos \varepsilon)}{2}$$  \hspace{1cm} (13.18)

where $\rho_g$ is the ground reflectivity. The total diffuse irradiation on a given surface will be the sum of $Ed$ and $Er$ when the input for diffuse solar radiation is taken from the solar calculator. Otherwise, if the constant option is selected in the Radiation dialog box, then the total diffuse irradiation will be the same as specified in the dialog box.

### 13.3.10.4.3. Computation of Load Distribution

In calculating the solar load that will be incident on each surface, it is necessary to distinguish between the calculation of diffuse and direct solar loads. A direct load will be tracked from participating transmissive boundary surfaces and non-participating boundary surfaces, the former provides some opportunity to attenuate the incoming flux by absorption and reflection, while the non-participating surfaces allow the flux to enter without any drop in intensity. The direct load is then tracked through the model space until it is incident on an opaque surface, or it exists through a transmissive or non-participating boundary zone. During its passage, its intensity will be attenuated as it passes through participating semi-transparent internal walls, where some radiation may be absorbed and some may be reflected. The total amount of direct radiation that is reflected at internally facing surfaces will be added to the scattered radiation budget for further use later.

The diffuse load originates at participating transmissive boundary surfaces. It is these surfaces that permit diffuse radiation to enter, irrespective of their orientation relative to the direction vector. For each transmissive surface, some of the incoming diffuse load may be immediately absorbed and/or reflected to the outside. The rest is assumed to be transmitted inside and summed from all of these surfaces to give an initial diffuse budget. Onto this budget is added a fraction of the previously computed scattered radiation from the direct load, the fraction used is defined as an input to the model. This provides the total diffuse load. This is then uniformly distributed across all surfaces that are participating in the solar calculation, irrespective of whether they are opaque or semi-transparent. There is no scope to define local absorptivity for this distribution and no biasing with regards proximity to transmissive boundary surfaces.
surfaces. Note that a non-participating boundary zone will allow direct load to enter the model space but will not provide an incoming quantity of diffuse load.

Note that the solar flux that is externally incident on an opaque surface will be completely disregarded, for example solar load on an opaque roof of a model whose internals only are modeled will not be included as a heat gain. Instead, this heat gain should be manually calculated and applied as a thermal condition, typically using a fixed heat flux or a radiation/mixed condition.

13.3.10.5. Using the Solar Load Model

When you want to run a steady-state solution with solar load enabled, you simply set up the solar load model (Setting Up the Solar Load Model (p. 823)) and boundary conditions (Setting Boundary Conditions for Solar Loading (p. 829)) for your case, and then run the simulation. The solution data file will contain the solar fluxes that you can use for postprocessing. For a steady-state solution, the solar loads are computed on initialization. If you want to initially solve a case without solar loading (say, for stability) and then add the effects of solar loading afterward, you will need to enable the solar load model through the text user interface (TUI).

---

Important

Note that you can compute the solar load at any time once you have set up the model by using the sol-on-demand text interface command (see Additional Text Interface Commands (p. 838) for details).

---

When you want to run a transient solar load simulation, the process is the same as for the steady-state case but you will need to specify the additional Time Steps per Solar Load Update parameter in the Radiation Model dialog box. ANSYS Fluent will re-compute the sun position and irradiation and update solar loads with this specified frequency.

---

Important

Note that parallel simulations involving the solar load model are set up and computed using the same steps as in serial.

13.3.10.5.1. User-Defined Functions (UDFs) for Solar Load

You can write a user-defined function (UDF) to specify direct and diffuse solar intensity using the DEFINE_SOLAR_INTENSITY macro. See DEFINE_SOLAR_INTENSITY in the UDF Manual for more information. After it is interpreted or compiled, you can hook your intensity UDF for direct or diffuse solar irradiation by selecting user-defined in the drop-down lists for these parameters in the Radiation Model dialog box. See Step 2 in Setting Up the Solar Load Model (p. 823) for details.

13.3.10.5.2. Setting Up the Solar Load Model

The solar load model is enabled in the Radiation Model dialog box (Figure 13.29: The Radiation Model Dialog Box (p. 824)).

Models → Radiation → Edit...
Important

Solar load is available in the 3D solver only, and can be used to model steady and unsteady flows.

The solar load model has two options: Solar Ray Tracing and DO Irradiation. Solar Ray Tracing can be applied as a standalone solar loading model, or it can be used in conjunction with one of the ANSYS Fluent radiation models (P1, Rosseland, Discrete Transfer, Surface-to-Surface, Discrete Ordinates). DO Irradiation is available only when the Discrete Ordinates (DO) radiation model is enabled.

To set up the solar load model, perform the following steps:

1. Enable the solar load model in the Radiation Model Dialog Box.

   a. To enable the solar ray tracing algorithm, select Solar Ray Tracing under Solar Load (Figure 13.30: The Radiation Model Dialog Box (With Solar Load Model Solar Ray Tracing Option) (p. 825)).
Figure 13.30: The Radiation Model Dialog Box (With Solar Load Model Solar Ray Tracing Option)

b. To enable the DO irradiation option, first select **Discrete Ordinates** under **Model**, and then select **DO Irradiation** under **Solar Load** (Figure 13.31: The Radiation Model Dialog Box (with Solar Load Model DO Irradiation Option) (p. 826)).
2. Define the solar parameters.
   
a. Enter values for the \(X\), \(Y\), and \(Z\) components of the **Sun Direction Vector**. Alternatively, you can choose to have this vector computed from the solar calculator by enabling the **Use Direction Computed from Solar Calculator** option.

b. Specify the illumination parameters.
   
i. Enter a value for **Direct Solar Irradiation** under **Illumination Parameters**. This parameter is the amount of energy per unit area in \(W/m^2\) due to direct solar irradiation. This value may depend on the time of year and the clearness of the sky. Make your selection in the drop-down list next to **Direct Solar Irradiation** and either enter a **constant** value, have the value computed from the solar calculator, or specify it using a **user-defined function**. (For more information on writing solar intensity UDFs, see **DEFINE_SOLAR_INTENSITY** in the **UDF Manual**.) For transient simulations, you have the additional option of specifying a time-dependent **piecewise-linear** and **polynomial** profile for direct solar irradiation.
ii. Enter a value for **Diffuse Solar Irradiation**, which is the amount of energy per unit area in $W/m^2$ due to diffuse solar irradiation. This value may depend on the time of year, the clearness of the sky, and also on ground reflectivity. Make your selection in the drop-down list next to **Diffuse Solar Irradiation** and either enter a constant value, have the value computed from the solar calculator, or specify it using a user-defined function. (For more information on writing solar intensity UDFs, see **DEFINE_SOLAR_INTENSITY** in the UDF Manual.) For transient simulations, you have the additional option of specifying a time-dependent piecewise-linear and polynomial profile for diffuse solar irradiation.

iii. If you are using the **Solar Ray Tracing** solar load model (Figure 13.30: The Radiation Model Dialog Box (With Solar Load Model Solar Ray Tracing Option) (p. 825)), then you will need to enter a value for **Spectral Fraction**. The spectral fraction is the fraction of incident solar radiation in the visible part of the solar radiation spectrum. The spectral fraction is not used for DO irradiation since the DO implementation is intended only for a single band.

$$\text{Spectral Fraction} = \frac{V}{V + IR} \tag{13.19}$$

where $V$ is the visible incident solar radiation, and $V + IR$ is the total incident solar radiation (visible plus infrared).

3. Use the solar calculator to compute solar beam direction and irradiation.

   a. Click **Solar Calculator...** in the **Radiation Model** dialog box to open the **Solar Calculator** dialog box (Figure 13.32: The Solar Calculator Dialog Box (p. 827)).

   **Figure 13.32: The Solar Calculator Dialog Box**

   ![Solar Calculator Dialog Box]

   b. In the **Solar Calculator** dialog box, define the **Global Position** by the following parameters:

      i. Enter a real number in degrees for **Longitude**. Values may range from $-180$ to $180$ where negative values indicate the Western hemisphere and positive values indicate the Eastern hemisphere.
ii. Enter a real number for **Latitude** in degrees. Values can range from \(-90^\circ\) (the South Pole) to \(90^\circ\) (the North Pole), with \(0^\circ\) defined as the equator.

iii. Enter an integer for **Timezone** that is the local time zone in hours relative to Greenwich Mean Time (+-GMT). This value can range from +12 to −12.

---

**Important**

Note that you must specify all three **Global Position** parameters for the solar calculator.

c. Define the local **Date and Time** by the following parameters:

i. Enter an integer for **Day** and **Month** under **Day of Year**.

ii. Enter an integer for **Hour** that ranges from 0 to 24 under **Time of Day**. Enter an integer or floating point number for **Minute**.

   The time of day is based on a 24-hour clock: 0 hours and 0 minutes corresponds to 12:00 a.m. and 23 hours 59.99 min corresponds to 11:59.99 p.m. For example, if the local time was 12:01:30 a.m., you would enter 0 for **Hour** and 1.5 for **Minute**. If the local time was 4:17 p.m., you would enter 16 for **Hour** and 17 for **Minute**.

d. Define the **Mesh Orientation** as the vectors for North and East in the CFD mesh system of coordinates.

e. Select the appropriate **Solar Irradiation Method**. The **Fair Weather Conditions** is the default method.

f. Enter an integer for **Sunshine Fraction** (default = 1).

g. Click **Apply**.

The solar calculator output parameters are computed and the results are reported in the console. The default values are shown below:

Fair Weather Conditions:
- Sun Direction Vector: X: -0.0785396, Y: 0.170758, X: 0.982178
- Sunshine Fraction: 1
- Direct Normal Solar Irradiation (at Earth’s surface) [W/m^2]: 881.635
- Diffuse Solar Irradiation - vertical surface: [W/m^2]: 152.107
- Diffuse Solar Irradiation - horizontal surface: [W/m^2]: 118.727
- Ground Reflected Solar Irradiation - vertical surface: [W/m^2]: 96.4649

4. For transient simulations, enter the **Time Steps Per Solar Load Update** under **Update Parameters**. The number of time steps that you specify will direct the ANSYS Fluent solver to update the solar load data for the specified flow-time intervals in the unsteady solution process.
13.3.10.5.3. Setting Boundary Conditions for Solar Loading

Once you have defined the solar parameters for the solar load model (Setting Up the Solar Load Model (p. 823)), you will need to set up boundary conditions for boundary zones that will participate in solar loading.

**Boundary Conditions**

13.3.10.5.4. Solar Ray Tracing

1. Set the boundary condition for each inlet and exit boundary zone that you want to include in solar loading.

   a. Open the inlet or exit boundary condition dialog box (for example, *Velocity Inlet*) and click the *Radiation* tab (Figure 13.33: The Velocity Inlet Dialog Box (p. 829)).

   ![Figure 13.33: The Velocity Inlet Dialog Box](image)

   b. Enable the *Participates in Solar Ray Tracing* option (this option is enabled for all boundary conditions by default). If you deactivate solar ray tracing by disabling this option the surface will be ignored and the solar ray will pass through it with no interaction, regardless of the boundary condition type.
c. Enter a value between 0 and 1 for the **Solar Transmissivity Factor**. This will allow you to control the amount of solar irradiation entering the domain. By reducing the solar transmissivity factor from 1 to 0.5, you can effectively cut the total internal energy source entering the domain by half.

---

**Important**

Note that the solar transmissivity factor is applied to both direct and diffuse solar irradiation components.

---

d. Click **OK**.

2. Set the boundary condition for each wall boundary zone that you want to include in solar loading.

   a. Open a **Wall** boundary condition dialog box and click the **Radiation** tab.

   b. Define the wall as **opaque** or **semi-transparent**. An opaque wall will not allow any solar radiation to pass through it, while a semi-transparent surface will allow a portion of the solar radiation to pass through it.)

   i. For an opaque wall, select **opaque** from the drop-down list for **BC Type** (Figure 13.34: The Wall Dialog Box (p. 831)). Then enable the **Participates in Solar Ray Tracing** option (this option is enabled for all boundary conditions by default) in the **Solar Boundary Conditions** group box and enter constant values for **Direct Visible** and **Direct IR** absorptivity. Note that if you deactivate solar ray tracing by disabling the **Participates in Solar Ray Tracing** option, the surface will be ignored and the solar ray will pass through it with no interaction, regardless of the boundary condition type.

---

**Important**

Absorption in the visible and infrared portions of the spectrum define the surface material for the opaque wall.
For a semi-transparent wall, select **semi-transparent** from the drop-down list for BC Type (Figure 13.35: The Wall Dialog Box (p. 832)). Then, enable the **Participates in Solar Ray Tracing** option (this option is enabled for all boundary conditions by default) in the Solar Boundary Conditions group box and enter constant values for Direct Visible, Direct IR, and Diffuse Hemispherical absorptivity and transmissivity. Note that if you deactivate solar ray tracing by disabling the **Participates in Solar Ray Tracing** option, the surface will be ignored and the solar ray will pass through it with no interaction, regardless of the boundary condition type.
Absorption and transmittance in the visible and infrared portions of the spectrum, as well as the “shading” formulation (Diffuse Hemispherical), define the surface material for a semi-transparent wall. These parameters are properties of the glazed unit and should be provided by the glazing manufacturer. The direct components are based on normal incident radiation (ANSYS Fluent adjusts this for the actual angle of incidence). Most manufacturers present this information in a slightly different way so it may be necessary to seek guidance from the supplier. Another useful source of data can be found in the ASHRAE Fundamentals Handbook, chapter on Fenestration.

iii. Click OK.

Important

ANSYS Fluent will calculate the reflectivity as the difference between one and the sum of absorptivity and transmissivity:

\[ \text{reflectivity} = 1 - (\text{absorptivity} + \text{transmissivity}) \]  \hspace{1cm} (13.20)

3. Set the boundary condition for each porous jump boundary zone that you want to include in solar loading. You can define the boundary such that it acts as a semi-transparent surface that will allow a portion of the solar radiation to pass through it, along with fluid flow. In this way you can represent a partial opening (for example, a grate, a grill, or a louver) that is a combination of gaps and (typically) opaque surfaces.

a. Open the Porous Jump boundary condition dialog box (Figure 13.36: The Porous Jump Dialog Box (p. 833)).
b. Define the **Face Permeability**, **Porous Medium Thickness**, and **Pressure-Jump Coefficient**, as described in **User Inputs for the Porous Jump Model (p. 350)**.

c. Define the settings in the **Solar Boundary Conditions** group box.

   i. Enable the **Participates in Solar Ray Tracing** option (this option is enabled for all boundary conditions by default). Note that if you deactivate solar ray tracing by disabling the **Participates in Solar Ray Tracing** option, the surface will be ignored and the solar ray will pass through it with no interaction, regardless of the boundary condition type.

   ii. Enter constant values (between 0 and 1) for **Direct Visible** and **Direct IR** in the **Absorptivity** group box. These values act as multipliers for the visible and infrared portions of the direct solar radiation spectrum, respectively, to account for the absorption of the porous jump.

   **Important**

   One reasonable way to estimate the **Direct Visible** and **Direct IR** absorptivity values for a grill, etc., is to use the product of the obstructed area fraction and the surface absorptivity. For example, if 40% of the grill facial area is obstructed with grill slats, and the slats have a surface absorptivity of 0.7, you could estimate the absorptivity as being 0.28.
iii. Enter constant values (between 0 and 1) for **Direct Visible** and **Direct IR** in the **Transmissivity** group box. These values act as multipliers for the visible and infrared portions of the direct solar radiation spectrum, respectively, to account for the transmissivity of the porous jump.

**Important**

One reasonable way to estimate the **Direct Visible** and **Direct IR** transmissivity values for a grill, etc., is to use the open area fraction. For example, if a grill has openings between the slats that amount to 60% of the area, you could estimate the transmissivity as being 0.6.

d. Click **OK**.

### 13.3.10.5.5. DO Irradiation

1. For DO irradiation, all boundary conditions are set up as normal for the DO model, except that now you can select semi-transparent boundary surfaces that will provide a source of solar irradiation.

   a. Open a **Wall** boundary condition dialog box and click the **Radiation** tab (**Figure 13.37: The Wall Dialog Box (p. 835)**).
b. Select **semi-transparent** from the drop-down list for **BC Type**.

c. Enable the **Use Beam Direction from Solar Load Model Settings** option, under **Solar BC Options**, to have the values for beam direction applied from the **Solar Load Model** settings in the **Radiation** dialog box.

**Important**

Note that the sign of the beam direction that is needed for the DO model is opposite the sun direction vector that is entered or derived from the solar parameters. The beam direction in the DO model is the direction of external radiation (for example, radiation coming from the sun), while the sun direction vector in the solar load model points to the sun. Incident radiation and sun angle always have an opposite sign since they are quantities that are defined from opposite perspectives.
d. Enable the **Use Direct and Diffuse Irradiation from Solar Load Model Settings** option to have the solar calculator output be applied for direct and diffuse irradiation.

   When **Use Direct and Diffuse Irradiation from Solar Load Model Settings** is enabled, the beam width will automatically be set to 0°, 53 degrees - the angle subtended by the sun.

e. Click **OK**.

### 13.3.10.5.6. Text Interface-Only Commands

ANSYS Fluent has provided some additional commands for solar load setup that are only available in the text interface. These commands are present in the following sections.

#### 13.3.10.5.6.1. Automatically Saving Solar Ray Tracing Data

It is possible to direct ANSYS Fluent to automatically save solar load data to a generic file that you can examine or use in an external program. This is done by executing the text command `autosave-solar-data` from the text interface.

```plaintext
define → models → radiation → solar-parameters → autosave-solar-data
```

1. Enter a value for the autosave solar data file frequency when prompted, in order to specify the frequency (in time steps) at which you want the solar load data written to a file. The default value is zero, which means that no automatic saving is performed.
2. Enter the filename, in quotations.
3. Choose to write file in binary format.

The text interface command for `autosave-solar-data` for a file named `solar` and a frequency of 1 is shown below:

```plaintext
/define/models/radiation/solar-parameters> autosave-solar-data
Autosave Solar Data File Frequency [0] 1
Enter Filename ["]" solar"
```

#### 13.3.10.5.6.2. Automatically Reading Solar Data

When you are executing a transient simulation in parallel ANSYS Fluent and you want to take solar loading conditions into consideration, you can use the `autoread-solar-data` text command to automatically read the solar load data file you generated during a serial run into parallel ANSYS Fluent. This is done by executing the text command `autoread-solar-data` from the text interface.

```plaintext
define → models → radiation → solar-parameters → autoread-solar-data
```

1. Enter a value for the autoread solar data file frequency when prompted, in order to specify the frequency (in time steps) at which you want the solar load data read from the file generated during the serial run. The default value is zero, which means that no automatic reading is performed.
2. Enter the filename, in quotations.

The text interface command for `autoread-solar-data` for a file named `solar` and a frequency of 1 is shown below:

```plaintext
/define/models/radiation/solar-parameters> autoread-solar-data
Autoread Solar Data File Frequency [0] 1
```
13.3.10.5.6.3. Aligning the Camera Direction With the Position of the Sun

When the solar load model is enabled, you can direct ANSYS Fluent to align the camera direction with the sun position using the text interface command:

```
define models radiation solar-parameters sol-camera-pos
```

This command is useful when you are executing a transient simulation and you want to capture an image of your model with solar load parameters displayed (such as solar heat flux) as the sun position changes with time in order to create an animation. See Postprocessing Solar Load Quantities (p. 838) for details.

13.3.10.5.6.4. Specifying the Scattering Fraction

You can modify the default scattering fraction (I) using the text interface command:

```
define models radiation solar-parameters scattering-fraction
```

The scattering fraction is the amount of direct radiation that has been reflected from opaque surfaces (after entering through the transparent surfaces) that will be considered to remain within the space and be evenly distributed among all surfaces. The value is between 0 and 1.

The text interface command for specifying a scattering-fraction of 0.5 is shown below:

```
/define/models/radiation/solar-parameters> scattering-fraction
Scattering Fraction [1] 0.5
```

13.3.10.5.6.5. Applying the Solar Load on Adjacent Fluid Cells

You can direct ANSYS Fluent to apply the solar load that is computed from the solar ray tracing algorithm to adjacent fluid cells by issuing the following command at the text interface:

```
define models radiation solar-parameters sol-adjacent-fluidcells
```

The text interface command is shown below:

```
/define/models/radiation/solar-parameters> sol-adjacent-fluidcells
Apply Solar Load on adjacent Fluid Cells? [no] y
```

This command allows you to apply solar loads to adjacent fluid cells only, even if solid or shell conduction zones are present. By applying the solar load on adjacent fluid cells, you are overruling the default order of the adjacent cell assignment in ANSYS Fluent which is shell, solid, fluid.

13.3.10.5.6.6. Specifying Quad Tree Refinement Factor

You can modify the default value (7) for the maximum quad tree refinement factor in the solar ray tracing algorithm using the text command:

```
define models radiation solar-parameters quad-tree-parameters
```

The text interface command is shown below, when a new maximum refinement value of 10 is specified:

```
/define/models/radiation/solar-parameters> quad-tree-parameters
Maximum Quad-Tree Refinement [7] 10
```
13.3.10.5.6.7. Specifying Ground Reflectivity

You can modify the default value (0.2) for the ground reflectivity using the text command:

\[ \text{define \models \radiation \solar-parameters \ground-reflectivity} \]

Ground reflectivity \( \rho_g \) (Equation 13.18 (p. 822)) includes the contribution of reflected solar radiation from ground surfaces. It is treated as part of the total diffuse solar irradiation when the solar calculator is used in conjunction with the Diffuse Solar Irradiation illumination parameter. The default value is 0.2.

```
/define/models/radiation/solar-parameters> ground-reflectivity
Ground Reflectivity [0.2] 0.5
```

13.3.10.5.6.8. Additional Text Interface Commands

Some solar load commands that are available in the graphical user interface are also made available in the text interface. For example, you can turn the solar load model on using the text command:

\[ \text{define \models \radiation \solar?} \]

You can also enter the solar calculator parameters in the text interface by executing the command:

\[ \text{define \models \radiation \solar-calculator} \]

Once invoked, you will be prompted to enter the solar calculator input parameters.

To set the illumination parameters, select this option from the solar-parameters menu:

\[ \text{define \models \radiation \solar-parameters \illumination-parameters} \]

And finally, you can direct ANSYS Fluent to compute the solar load on demand, by issuing the text command:

\[ \text{define \models \radiation \solar-parameters \sol-on-demand} \]

When the command is initiated, the solar data are written to the console.

13.3.10.6. Postprocessing Solar Load Quantities

The following solar load quantities can be used to visualize the illuminated areas and shadows created by solar radiation.

- solar heat flux (that is, sum of visible and IR absorbed solar flux on opaque walls)
- absorbed visible and IR solar flux (semi-transparent walls and porous jump boundaries only)
- reflected visible and IR solar flux (semi-transparent walls and porous jump boundaries only)
- transmitted visible and IR solar flux (semi-transparent walls and porous jump boundaries only)

These quantities are available for postprocessing of solar loading at wall boundaries and can be displayed as contours of **Wall Fluxes** in the **Contours** dialog box. For steady-state simulations, the solar flux data is computed at solution initialization and is available for postprocessing. You can also compute the solar load at any time during your ANSYS Fluent session, after you have set up the model and applied
boundary conditions. To compute the solar load on demand, you can issue the `sol-on-demand` command in the text interface (see Additional Text Interface Commands (p. 838) for details).

Solar heat flux, for example, can be displayed for surfaces using the Contours dialog box. A sample dialog box is shown below (Figure 13.38: The Contours Dialog Box (p. 839)).

Figure 13.38: The Contours Dialog Box

13.3.10.6.1. Solar Load Animation at Different Sun Positions

The solar camera alignment command is useful when you want to take timed pictures of solar loading effects of your model during transient simulations, and later create animations of the image files using an external program. Follow the procedure below.

1. Read (or set up) your transient case file in ANSYS Fluent.

2. Set up the automatic execution of solution commands in the Execute Commands dialog box that will: 1) display solar load parameter graphics, 2) re-position the solar camera such that the view is aligned with the instantaneous sun direction, and 3) generate a picture image file (.tiff) during the solution process in the Execute Commands dialog box.

   Calculation Activities (Execute Commands) → Create/Edit...

3. Initialize and run the solution.

4. Animate the .tiff files using an external animation tool.
The following commands entered in the **Execute Commands** dialog box will direct ANSYS Fluent to display contours of solar heat flux, align the camera with the current direction of the sun, and then generate a picture image file (.tiff) of the solar heat flux contour every 300 time steps during the unsteady simulation. See Figure 13.39: The Execute Commands Dialog Box (p. 840).

```
di/cont solar-heat-flux,,
def/mod/rad/solar-para/sol-camera-pos
di/hc "flux-%t.tiff"
```

**Figure 13.39: The Execute Commands Dialog Box**

### 13.3.10.6.2. Reporting and Displaying Solar Load Quantities

ANSYS Fluent provides some additional solar load variables that you can use for postprocessing when your model includes solar ray tracing. You can generate graphical plots or alphanumeric reports of the following variables:

In the **Wall Fluxes...** category:

- **Solar Heat Flux**
- **Transmitted Visible Solar Flux** (semi-transparent walls and porous jump boundaries)
- **Transmitted IR Solar Flux** (semi-transparent walls and porous jump boundaries)
- **Reflected Visible Solar Flux** (semi-transparent walls and porous jump boundaries)
- **Reflected IR Solar Flux** (semi-transparent walls and porous jump boundaries)
- **Absorbed Visible Solar Flux** (semi-transparent walls and porous jump boundaries)
- **Absorbed IR Solar Flux** (semi-transparent walls and porous jump boundaries)

See Field Function Definitions (p. 1765) for their definitions.

### 13.4. Modeling Periodic Heat Transfer

ANSYS Fluent is able to predict heat transfer in periodically repeating geometries, such as compact heat exchangers, by including only a single periodic module for analysis.
This section discusses streamwise-periodic heat transfer. The treatment of streamwise-periodic flows is discussed in Periodic Flows (p. 514), and a description of no-pressure-drop periodic flow is provided in Periodic Boundary Conditions (p. 332).

Information about streamwise-periodic heat transfer is presented in the following sections:

13.4.1. Overview and Limitations
13.4.2. Theory
13.4.3. Using Periodic Heat Transfer
13.4.4. Solution Strategies for Periodic Heat Transfer
13.4.5. Monitoring Convergence
13.4.6. Postprocessing for Periodic Heat Transfer

13.4.1. Overview and Limitations

The following sections contain information about periodic heat transfer:

13.4.1.1. Overview
13.4.1.2. Constraints for Periodic Heat Transfer Predictions

13.4.1.1. Overview

As discussed in Overview and Limitations (p. 514), streamwise-periodic flow conditions exist when the flow pattern repeats over some length \( L \), with a constant pressure drop across each repeating module along the streamwise direction.

Periodic thermal conditions may be established when the thermal boundary conditions are of the constant wall temperature or wall heat flux type. In such problems, the temperature field (when scaled in an appropriate manner) is periodically fully developed [69] (p. 2560). As for periodic flows, such problems can be analyzed by restricting the numerical model to a single module or periodic length.

13.4.1.2. Constraints for Periodic Heat Transfer Predictions

In addition to the constraints for streamwise-periodic flow discussed in Limitations for Modeling Streamwise-Periodic Flow (p. 515), the following constraints must be met when periodic heat transfer is to be considered:

• The pressure-based solver must be used.

• The thermal boundary conditions must be of the specified heat flux or constant wall temperature type. Furthermore, in a given problem, these thermal boundary types cannot be combined: all boundaries must be either constant temperature or specified heat flux. You can, however, include constant-temperature walls and zero-heat-flux walls in the same problem. For the constant-temperature case, all walls must be at the same temperature (profiles are not allowed) or zero heat flux. For the heat flux case, profiles and/or different values of heat flux may be specified at different walls.

• When constant-temperature wall boundaries are used, you cannot include viscous heating effects or any volumetric heat sources.

• In cases that involve solid regions, the regions cannot straddle the periodic plane.

• The thermodynamic and transport properties of the fluid (heat capacity, thermal conductivity, viscosity, and density) cannot be functions of temperature. (You cannot, therefore, model reacting flows.) Transport properties may, however, vary spatially in a periodic manner, and this allows you to model periodic turbulent flows in which the effective turbulent transport properties (effective conductivity, effective viscosity) vary with the (periodic) turbulence field.
Theory (p. 842) and Using Periodic Heat Transfer (p. 843) provide more detailed descriptions of the input requirements for periodic heat transfer.

13.4.2. Theory

Streamwise-periodic flow with heat transfer from constant-temperature walls is one of two classes of periodic heat transfer that can be modeled by ANSYS Fluent. A periodic fully developed temperature field can also be obtained when heat flux conditions are specified. In such cases, the temperature change between periodic boundaries becomes constant and can be related to the net heat addition from the boundaries as described in this section.

Important

Periodic heat transfer can be modeled only if you are using the pressure-based solver.

13.4.2.1. Definition of the Periodic Temperature for Constant-Temperature Wall Conditions

For the case of constant wall temperature, as the fluid flows through the periodic domain, its temperature approaches that of the wall boundaries. However, the temperature can be scaled in such a way that it behaves in a periodic manner. A suitable scaling of the temperature for periodic flows with constant-temperature walls is [69] (p. 2560)

\[ \theta = \frac{T(\bar{r} + \bar{L}) - T_{\text{wall}}}{T_{\text{bulk,inlet}} - T_{\text{wall}}} \]  

(13.21)

The bulk temperature, \( T_{\text{bulk,inlet}} \), is defined by

\[ T_{\text{bulk,inlet}} = \frac{\int T \rho \bar{V} \cdot d\bar{A}}{\int \rho \bar{V} \cdot d\bar{A}} \]  

(13.22)

where the integral is taken over the inlet periodic boundary (\( A \)). It is the scaled temperature, \( \theta \), which obeys a periodic condition across the domain of length \( L \).

13.4.2.2. Definition of the Periodic Temperature Change \( \sigma \) for Specified Heat Flux Conditions

When periodic heat transfer with heat flux conditions is considered, the form of the unscaled temperature field becomes analogous to that of the pressure field in a periodic flow:

\[ \frac{T(\bar{r} + \bar{L}) - T(\bar{r})}{L} = \frac{T(\bar{r} + 2\bar{L}) - T(\bar{r} + \bar{L})}{L} = \sigma. \]  

(13.23)

where \( \bar{L} \) is the periodic length vector of the domain. This temperature gradient, \( \sigma \), can be written in terms of the total heat addition within the domain, \( Q \), as

\[ \sigma = \frac{Q}{mc_pL} = \frac{T_{\text{bulk,exit}} - T_{\text{bulk,inlet}}}{L}. \]  

(13.24)
where \( \dot{m} \) is the specified or calculated mass flow rate.

### 13.4.3. Using Periodic Heat Transfer

A typical calculation involving both streamwise-periodic flow and periodic heat transfer is performed in two parts. First, the periodic velocity field is calculated (to convergence) without consideration of the temperature field. Next, the velocity field is frozen and the resulting temperature field is calculated. These periodic flow calculations are accomplished using the following procedure:

1. Set up a mesh with translationally periodic boundary conditions.
2. Input constant thermodynamic and molecular transport properties.
3. Specify either the periodic pressure gradient or the net mass flow rate through the periodic boundaries.
4. Compute the periodic flow field, solving momentum, continuity, and (optionally) turbulence equations.
5. Specify the thermal boundary conditions at walls as either heat flux or constant temperature.
6. Define an inlet bulk temperature.
7. Solve the energy equation (only) to predict the periodic temperature field.

In order to model the periodic heat transfer, you will need to set up your periodic model in the manner described in [User Inputs for the Pressure-Based Solver (p. 515)] for periodic flow models with the pressure-based solver, noting the restrictions discussed in [Limitations for Modeling Streamwise-Periodic Flow (p. 515)] and [Constraints for Periodic Heat Transfer Predictions (p. 841)]. In addition, you will need to provide the following inputs related to the heat transfer model:

1. Activate solution of the energy equation in the Energy dialog box.
   
   ![Models → Energy → Edit...](image)

2. Define the thermal boundary conditions according to one of the following procedures:

   ![Boundary Conditions](image)

   - If you are modeling periodic heat transfer with specified-temperature boundary conditions, set the wall temperature \( T_{wall} \) for all wall boundaries in their respective Wall dialog box. Note that all wall boundaries must be assigned the same temperature and that the entire domain (except the periodic boundaries) must be "enclosed" by this fixed-temperature condition, or by symmetry or adiabatic \( (q=0) \) boundaries.
   - If you are modeling periodic heat transfer with specified-heat-flux boundary conditions, set the wall heat flux in the Wall dialog box for each wall boundary. You can define different values of heat flux on different wall boundaries, but you should have no other types of thermal boundary conditions active in the domain.

3. Define solid regions, if appropriate, according to one of the following procedures:

   ![Cell Zone Conditions](image)
• If you are modeling periodic heat transfer with specified-temperature conditions, conducting solid regions can be used within the domain, provided that on the perimeter of the domain they are enclosed by the fixed-temperature condition. Heat generation within the solid regions is not allowed when you are solving periodic heat transfer with fixed-temperature conditions.

• If you are modeling periodic heat transfer with specified-heat-flux conditions, you can define conducting solid regions at any location within the domain, including volumetric heat addition within the solid, if desired.

4. Set constant material properties (density, heat capacity, viscosity, thermal conductivity), not temperature-dependent properties, using the Create/Edit Materials dialog box.

5. Specify the Upstream Bulk Temperature in the Periodic Conditions dialog box.

6. Set the solution parameters as described in Solution Strategies for Periodic Heat Transfer (p. 844).

7. Run the solution and monitor the convergence as described in Monitoring Convergence (p. 845).

8. Postprocess the results as described in Postprocessing for Periodic Heat Transfer (p. 845).

13.4.4. Solution Strategies for Periodic Heat Transfer

After completing the inputs described in Using Periodic Heat Transfer (p. 843), you can solve the flow and heat transfer problem to convergence. The most efficient approach to the solution, however, is a sequential one in which the periodic flow is first solved without heat transfer and then the heat transfer is solved leaving the flow field unaltered. This sequential approach is accomplished as follows:

1. Disable solution of the energy equation in the Equations dialog box, accessed via the Solution Controls task page.

2. Solve the remaining equations (continuity, momentum, and, optionally, turbulence parameters) to convergence to obtain the periodic flow field.

Important

When you initialize the flow field before beginning the calculation, use the mean value between the inlet bulk temperature and the wall temperature for the initialization of the temperature field.
3. Return to the **Solution Controls** task page and turn off solution of the flow equations and turn on the energy solution.

4. Solve the energy equation to convergence to obtain the periodic temperature field of interest.

While you can solve your periodic flow and heat transfer problems by considering both the flow and heat transfer simultaneously, you will find that the procedure outlined above is more efficient.

### 13.4.5. Monitoring Convergence

If you are modeling periodic heat transfer with specified-temperature conditions, you can monitor the value of the bulk temperature ratio

\[
\theta = \frac{T_{\text{wall}} - T_{\text{bulk,inlet}}}{T_{\text{wall}} - T_{\text{bulk,exit}}}
\]  

(13.25)

during the calculation using the **Statistic Monitors** dialog box to ensure that you reach a converged solution. Select **per/bulk-temp-ratio** as the variable to be monitored. See **Monitoring Statistics** (p. 1486) for details about using this feature.

### 13.4.6. Postprocessing for Periodic Heat Transfer

The actual temperature field predicted by ANSYS Fluent in periodic models will not be periodic, and viewing the temperature results during postprocessing will display this actual temperature field \((T(\vec{r}))\) of **Equation 13.21** (p. 842). The displayed temperature may exhibit values outside the range defined by the inlet bulk temperature and the wall temperature. This is permissible since the actual temperature profile at the inlet periodic face will have temperatures that are higher or lower than the inlet bulk temperature.

**Static Temperature** is found in the **Temperature...** category of the variable selection drop-down list that appears in postprocessing dialog boxes.

**Figure 13.40: Temperature Field in a 2D Heat Exchanger Geometry With Fixed Temperature Boundary Conditions** (p. 846) shows the temperature field in a periodic heat exchanger geometry.
Figure 13.40: Temperature Field in a 2D Heat Exchanger Geometry With Fixed Temperature Boundary Conditions
Chapter 14: Modeling Heat Exchangers

Many engineering systems, including power plants, climate control, and engine cooling systems typically contain tubular heat exchangers. However, for most engineering problems, it is impractical to model individual fins and tubes of a heat exchanger core. In principle, heat exchanger cores introduce a pressure drop to the primary fluid stream and transfer heat to a second fluid, a coolant, referred to here as the auxiliary fluid.

ANSYS Fluent provides two distinct methods of modeling a heat exchanger: the dual cell model and the macro model. These models can be used to compute the auxiliary fluid inlet temperature for a fixed heat rejection or the total heat rejection for a fixed auxiliary fluid inlet temperature. The dual cell model allows the solution of the passes of the auxiliary flow on a separate mesh, that is, other than the primary fluid mesh (see Figure 14.1: An Example of a Four-Pass Heat Exchanger (p. 847)), unlike the macro model, where the auxiliary flow passes are modeled as 1D flow.

**Figure 14.1: An Example of a Four-Pass Heat Exchanger**

![Four-Pass Heat Exchanger Diagram](image)

**Important**

Note that the heat exchanger models are not appropriate for modeling a cold-only flow; in such a case, you should instead use the porous media model, as described in *Porous Media Conditions* (p. 223).

For theoretical information about the various heat exchanger models, refer to *Heat Exchangers* in the *Theory Guide*.

The following sections contain information about the heat exchanger models:
14.1. Choosing a Heat Exchanger Model

ANSYS Fluent provides various options for modeling heat exchangers, each with their own features and limitations. The following instructions can help you determine which option/combination of options is the most appropriate for your problem.

1. Decide whether you want to use the dual cell model or the macro model.
   a. The dual cell model provides the greatest flexibility with regard to the shape of the heat exchanger core and the nature of the mesh, and allows the auxiliary fluid to be highly non-uniform as it enters the core (for example, due to passing through arbitrary shaped inlet tanks). However, the dual cell model may need to be discounted as an option because of the following limitations:
      • If the heat exchanger performance data that you have is in the form of a velocity vs. effectiveness curve, the dual cell model cannot be used.
      • The dual cell model does not allow you to model phase change in the auxiliary fluid.

      If the previous limitations are not relevant for your problem, you can proceed directly to using the dual cell model, as described in Using the Dual Cell Heat Exchanger Model (p. 850).

   b. While the macro model has more restrictions than the dual cell model, it is quite suitable for a thin 3D heat exchanger core with a rectangular cross section, where the pass-to-pass plane is perpendicular to the primary flow direction, the auxiliary flow is uniform, and the mesh is uniform and structured. To verify that your problem can tolerate the limitations of the macro model, see Restrictions (p. 859).

2. If you chose to use the macro model in the previous step, you must decide whether you want to use the grouped or ungrouped version of this model. If you want to define a single heat exchanger using multiple fluid zones, or if you would like to connect the fluid flow path among multiple heat exchangers, you should use the grouped version, as described in Using the Grouped Macro Heat Exchanger Model (p. 871). Otherwise, you can use the ungrouped version, as described in Using the Ungrouped Macro Heat Exchanger Model (p. 860).

3. If you chose to use the macro model in the step 1., you must decide whether you want to model the heat transfer using the number-of-transfer-units (NTU) method or the simple effectiveness method. This decision largely rests on the kind of experimental data that you have: the NTU method requires that you provide the various primary fluid flow rates and auxiliary fluid flow rates and the corresponding heat transfer values; the simple effectiveness method requires that you provide the data points for a curve that defines how the effectiveness (that is, the ratio of actual rate of heat transfer from the hot to cold fluid to the maximum possible rate of heat transfer) varies with the fluid velocity. Additionally, you should
consider the differences between the two heat transfer models outlined in Table 14.1: NTU Model Vs. Simple Effectiveness Model (p. 849).

Table 14.1: NTU Model Vs. Simple Effectiveness Model

<table>
<thead>
<tr>
<th></th>
<th>NTU Model</th>
<th>Simple Effectiveness Model</th>
</tr>
</thead>
<tbody>
<tr>
<td>How many phases are allowed in the auxiliary flow?</td>
<td>single phase only</td>
<td>single phase and two phase</td>
</tr>
<tr>
<td>What is the direction of heat transfer?</td>
<td>To and from the auxiliary fluid</td>
<td>From the auxiliary fluid only</td>
</tr>
<tr>
<td>Can you model primary fluid-side reverse flow?</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Can the primary fluid have a variable density?</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Must the primary fluid capacity be less than the auxiliary fluid capacity?</td>
<td>No</td>
<td>Yes</td>
</tr>
</tbody>
</table>

You will specify whether you want the NTU or simple effectiveness model in the Model Data tab of either the Ungrouped Macro Heat Exchanger dialog box or the Heat Exchanger Group dialog box, depending on whether you opted for the ungrouped or grouped version of the macro model, respectively.

An overview of the options available to you when modeling heat exchangers is shown in Figure 14.2: Heat Exchanger Modeling Options (p. 849).

**Figure 14.2: Heat Exchanger Modeling Options**

14.2. The Dual Cell Model

The dual cell heat exchanger model allows the solution of both the primary and auxiliary flow on separate co-located meshes and couples the two flows only through heat transfer at the heat exchanger core.

For theoretical information about this model, refer to The Dual Cell Model in the Theory Guide.
14.2.1. Restrictions

The following restrictions exist for the dual cell heat exchanger models:

• Heat transfer calculations are based on the NTU method only, as the simple effectiveness method is not available. See step 3 in Choosing a Heat Exchanger Model (p. 848) for details about the differences between these two models.

• In the case of a heat exchanger in which the primary and auxiliary meshes are not identical, heat transfer may be non-conservative (that is, the heat lost by the hot fluid may not equal the heat gained by the cold fluid). To minimize the difference in heat transfer, the topology and size of the primary and auxiliary cells should be similar. Note that you can make the meshes identical by copying a zone via the `mesh/modify-zones/copy-move-cell-zone` text command.

14.2.2. Using the Dual Cell Heat Exchanger Model

The steps for setting up the dual cell heat exchanger model is as follows:

1. Read the mesh file.

   a. If the mesh file does not already contain overlapping heat exchanger cores for primary and auxiliary fluids, then you must create a duplicate of the zone that represents the core using the following text command:

      ```
      mesh → modify-zones → copy-move-cell-zone
      ```

      See Copying Cell Zones (p. 191) for details on copying meshes.

   b. Make sure that the auxiliary fluid mesh is divided into separate zones, one for each pass.

      ```
      Mesh → Separate → Cells...
      ```

      See Separating Cell Zones (p. 180) for details on separating meshes.

2. Enable the calculation of energy in the Energy dialog box.

   ```
   Models → Energy → Edit...
   ```

3. Enable the Dual Cell Model in the Heat Exchanger Model dialog box and click Define... (Figure 14.3: The Heat Exchanger Model Dialog Box (p. 851)).

   ```
   Models → Heat Exchanger → Edit...
   ```
Figure 14.3: The Heat Exchanger Model Dialog Box

4. Specify the inputs to the dual cell heat exchanger model, using the Dual Cell Heat Exchanger dialog box (Figure 14.4: The Dual Cell Heat Exchanger Dialog Box (p. 851)).

Figure 14.4: The Dual Cell Heat Exchanger Dialog Box

5. Click New... to define the heat exchanger. The Set Dual Cell Heat Exchanger dialog box will appear (Figure 14.5: The Set Dual Cell Heat Exchanger Dialog Box (p. 852)), where you will define the heat exchanger parameters.
a. Enter the heat exchanger **Name** or keep the default name. The suffix \(-1\) is incremented automatically on defining more than one heat exchanger.

b. In the **Fluid Zones** tab (**Figure 14.5: The Set Dual Cell Heat Exchanger Dialog Box (p. 852)**)
   
   i. Specify the **Number of Passes** of your heat exchanger.

   ii. Select the appropriate **Primary** and **Auxiliary Fluid Zone**, representing the heat exchanger core.

   **Important**

   The selected zones must be overlapping in physical space.

c. Click the **Heat Rejection** tab (**Figure 14.6: The Heat Rejection Tab (p. 853)**).
If you select **Fixed Heat Rejection**, set the inputs for the following:

- **Heat Rejection Targeted** which is the heat rejection desired from the heat exchanger.
- **Inlet Zone for Temperature Updates** allows ANSYS Fluent to change the temperature of the specified inlet zone in order to match the targeted heat rejection.
- **Temperature Update Under-Relaxation** is a factor that controls convergence.
- **Iteration Interval Between Temperature Updates** is used to control divergence.

If you select **Fixed Inlet Temperature** if the output desired is total heat rejection.

Click the **Performance Data** tab (Figure 14.7: The Performance Data Tab (p. 854)).
Figure 14.7: The Performance Data Tab

If you select the **Raw Data** option, then specify the following:

- **Heat Transfer Data**... opens the Heat Transfer Data Table Dialog Box (p. 1931), where you will input experimental data that defines how heat transfer values relate to the fluid flow rates (Figure 14.8: The Heat Transfer Data Table Dialog Box (p. 855)). See Specifying Heat Exchanger Performance Data (p. 865) more details.
Figure 14.8: The Heat Transfer Data Table Dialog Box

- **Effectiveness-NTU Relation** computes the NTU values from the heat transfer data. Choose cross-flow-unmixed, parallel-flow, or counter-flow, all of which are described in NTU Relations.

- **Auxiliary Fluid Temperature** is the inlet reference temperature for the auxiliary fluid.

- **Primary Fluid Temperature** is the inlet reference temperature for the primary fluid.

ii. If you select the NTU Data option, click NTU Table... to access the NTU Table dialog box. Populate this table in the same manner as described previously for the Heat Transfer Data Table Dialog Box (p. 1931). More information is available in Specifying Heat Exchanger Performance Data (p. 865).

e. Click the Frontal Area tab. You have the option to input the Primary and Auxiliary Fluid Core Frontal Area directly, or compute the area from a surface zone, as shown in Figure 14.9: The Frontal Area Tab (p. 856).
Consider the following example illustrating the coupling of a four-pass heat exchanger.
Figure 14.11: An Example of a Four-Pass Heat Exchanger

Figure 14.11: An Example of a Four-Pass Heat Exchanger (p. 857) shows a four-pass heat exchanger with air as the primary fluid and the coolant as the auxiliary fluid. The coolant flows through the tubes in a serpentine manner and air flows normal to the tubes, forming a cross flow pattern.

To model this type of flow using the dual cell heat exchanger model, you must first generate the mesh. The mesh should contain the following:

i. A single primary cell zone.

ii. Four adjacent auxiliary cell zones, one for each pass. Each auxiliary zone should be separated from the other by a coupled or uncoupled wall. Each pass will have its own inlet and outlet zones.

iii. The primary and four auxiliary zones should overlap in physical space.

In the **Coupling** tab, **mass-weighted-average** is selected by default for the **Temperature** of the outlet of Pass 1 to the inlet of Pass 2. Similarly, the mass-weighted-average temperature of the outlet of Pass 2 will be applied at the inlet zone of Pass 3, and so on. Alternatively, you can couple the passes by using **Profiles...** in the **Boundary Conditions** task page. If you do so, make sure you select **none** from the **Temperature** drop-down list in the **Coupling** tab.

**Important**

Make sure to specify the auxiliary zones in the correct order (that is the zone for Pass 1 should be selected first, then Pass 2, and so on) in the **Fluid Zones** tab of the **Set Dual Cell Heat Exchanger** dialog box.

g. Click **Apply** to save the heat exchanger inputs.

6. To view the plot of NTU vs. primary mass flow rate for each auxiliary mass flow rate, click **Plot NTU**.
The Plot NTU button will plot the performance data curve for the selected heat exchanger. The performance data is supplied through the Performance Data tab.

When you close the Set Dual Cell Heat Exchanger dialog box, you will return to the Dual Cell Heat Exchanger dialog box, where you should now see the heat exchanger name in the Heat Exchanger list.

You can

• Modify the settings of heat exchanger by selecting it from the list and clicking Modify....

• Copy the data of one heat exchanger to another using the Copy button, assuming you have more than one heat exchanger.

• Delete any unwanted heat exchangers by selecting the heat exchanger from the list and clicking Delete.

Important

All the inputs are copied except for the name, primary fluid zone and auxiliary fluid zone.

14.3. The Macro Heat Exchanger Models

To use the macro heat exchanger model, you must define one or more fluid zone(s) to represent the heat exchanger core. Typically, the fluid zone is sized to the dimension of the core itself. As part of the setup procedure, you will define the auxiliary fluid path, the number of macros, and the physical properties and operating conditions of the core (pressure drop parameters, heat exchanger effectiveness, auxiliary fluid flow rate, etc.).

Additional information about macro heat exchangers can be found in Overview of the Macro Heat Exchanger Models in the Theory Guide. For the theory behind these models, refer to Macro Heat Exchanger Model Theory in the Theory Guide.

ANSYS Fluent provides two heat transfer models: the default NTU model and the simple effectiveness model. The simple effectiveness model interpolates the effectiveness from the velocity vs. effectiveness curve that you provide. For the NTU model, ANSYS Fluent calculates the effectiveness, \( e \), from the NTU value that is calculated by ANSYS Fluent from the heat transfer data provided by the you in tabular format. ANSYS Fluent will automatically convert this heat transfer data to a primary fluid mass flow rate vs. NTU curve (this curve will be piecewise linear). This curve will be used by ANSYS Fluent to calculate the NTU for macros based on their size and primary fluid flow rate.

The NTU model provides the following features:

• The model can be used to check heat capacity for both the primary and the auxiliary fluid and takes the lesser of the two for the calculation of heat transfer.

• The model can be used to model heat transfer to the primary fluid from the auxiliary fluid and vice versa.

• The model can be used to model primary fluid-side reverse flow.

• The model can be used with variable density of the primary fluid.

• The model can be used in either the serial or parallel ANSYS Fluent solvers.
The model can be used to make a network of heat exchangers using a heat exchanger group (Using the Grouped Macro Heat Exchanger Model (p. 871)).

- Transient profiles can be used for the coolant inlet temperature and for total heat rejection.
- Transient profiles can be used for auxiliary mass flow rates.

The simple effectiveness model provides the following features:

- The model can be used to model heat transfer from the auxiliary fluid to the fluid.
- The auxiliary fluid properties can be a function of pressure and temperature, therefore allowing phase change of the auxiliary fluid.
- The model can be used by serial as well as parallel solvers.
- The model can be used to make a network of heat exchangers using a heat exchanger group (Using the Grouped Macro Heat Exchanger Model (p. 871)).
- Transient profiles can be used for the coolant inlet temperature and for total heat rejection.
- Transient profiles can be used for auxiliary mass flow rates.

For additional information, see the following sections:

- 14.3.1. Restrictions
- 14.3.2. Using the Ungrouped Macro Heat Exchanger Model
- 14.3.3. Using the Grouped Macro Heat Exchanger Model

14.3.1. Restrictions

The following restrictions exist for the macro heat exchanger models:

- The core must be a 3D mesh with a cross section that is approximately rectangular in shape.
- The primary fluid streamwise direction (see Equation 6.1 in the Theory Guide) must be aligned with one of the three orthogonal axes defined by the rectangular core.
- The pass-to-pass plane must be perpendicular to the primary fluid streamwise direction.
- It is highly recommended that the free-form Tet mesh is not used in the macro heat exchanger model. Instead, evenly distributed Hex/Wedge cells should be used for improved accuracy and a more robust solution process.
- Flow acceleration effects are neglected in calculating the pressure loss coefficient.
- For the simple effectiveness model, the primary fluid capacity rate must be less than the auxiliary fluid capacity rate.
- Auxiliary fluid phase change cannot be modeled using the NTU model.
- The macro-based method requires that an equal number of cells reside in each macro of equal size and shape.
- Coolant flow is assumed to be 1D.
- The pass width has to be uniform.
• Accuracy is not guaranteed when the mesh is not structured or layered.

• Accuracy is not guaranteed when there is upstream diffusion of temperature at the inlet/outlet of the core.

• Non-conformal meshes cannot be attached to the inlet/outlet of the core. An extra layer has to be created to avoid it.

14.3.2. Using the Ungrouped Macro Heat Exchanger Model

The heat exchanger model settings may be written into and read from the boundary conditions file (Reading and Writing Boundary Conditions (p. 56)) using the text commands, file/write-settings and file/read-settings, respectively. Otherwise, the steps for setting up the ungrouped macro heat exchanger model is as follows:

1. Enable the calculation of energy in the Energy Dialog Box (p. 1903).

    Models → Energy → Edit...

2. Enable the Ungrouped Macro Model option and click the Define... button in the Heat Exchanger Model Dialog Box (p. 1927) (Figure 14.12: The Heat Exchanger Model Dialog Box (p. 860)) to access the Ungrouped Macro Heat Exchanger dialog box.

    Models → Heat Exchanger → Edit...

Figure 14.12: The Heat Exchanger Model Dialog Box

3. Specify the heat exchanger inputs in the Ungrouped Macro Heat Exchanger dialog box.
**Figure 14.13: The Ungrouped Macro Heat Exchanger Dialog Box Displaying the Model Data Tab**

![Macro Heat Exchanger Dialog Box](image)

- **Fluid Zone** drop-down list, select the fluid zone representing the heat exchanger core.
- Under the **Model Data** tab, choose **Fixed Heat Rejection** or **Fixed Inlet Temperature**, as required (Figure 14.13: The Ungrouped Macro Heat Exchanger Dialog Box Displaying the Model Data Tab (p. 861)).
- Specify the **Heat Transfer Model** as either the default **ntu-model** or the **simple-effectiveness-model**. See step 3 in Choosing a Heat Exchanger Model (p. 848) for details about the differences between these two models.
- Specify the **Core Porosity Model** if you want ANSYS Fluent to use the pressure loss coefficient function to automatically compute (and update) the porous media coefficients in the cell zones condition dialog box, as described in Streamwise Pressure Drop in the Theory Guide. More information is available in Setting the Pressure-Drop Parameters and Effectiveness (p. 869).
- If the **ntu-model** is chosen, a **Heat Transfer Data...** button will appear under **Heat Exchanger Performance Data**. Clicking the **Heat Transfer Data...** button will open the **Heat Transfer Data Table Dialog Box** (p. 1931), where you will input experimental data that defines how heat transfer values relate to the fluid flow rates (Figure 14.8: The Heat Transfer Data Table Dialog Box (p. 855)). See Specifying Heat Exchanger Performance Data (p. 865) more details.
f. Enter the **Auxiliary Fluid Temperature** and the **Primary Fluid Temperature** for the *ntu-model*. These are the fixed inlet temperatures at which the test was performed to obtain the heat transfer data.

g. If the **simple-effectiveness-model** is chosen, then clicking the **Velocity Effectiveness Curve**... button, under the **Heat Exchanger Performance Data**, allows you to set the velocity and corresponding effectiveness for each point. More information is available in *Specifying Heat Exchanger Performance Data* (p. 865).

h. In the **Geometry** tab, define the macro mesh using the **Number of Passes**, the **Number of Rows/Pass**, and the **Number of Columns/Pass** fields. The **Number of Rows/Pass** is along the auxiliary flow direction (height) and the **Number of Columns/Pass** is defined in the pass-to-pass (width) direction. Also, enter the **Auxiliary Fluid Inlet Direction** and **Pass-to-Pass Direction**. You may want to snap the plane tool to either the inlet or outlet of the heat exchanger using the **Update from Plane Tool**. Note that the plane tool must be attached exactly and oriented so that its green arrow points in the auxiliary flow direction, and its blue arrow points in the pass-to-pass direction.

---

**Important**

To attach the plane tool exactly, exact coordinates (printed in the console by probing) of the three corner nodes must be entered in the plane tool (x0, x1, x2) in a specific order. Also, note that x0 to x1 is the auxiliary flow direction and x1 to x2 is the pass-to-pass direction.
Figure 14.15: The Ungrouped Macro Heat Exchanger Dialog Box Displaying the Geometry Tab
i. In the **Auxiliary Fluid** tab, specify the **Auxiliary Fluid Properties Method**, either as a *constant-specific-heat* or as a *user-defined-enthalpy*.

j. **Auxiliary Fluid Flow Rate**, **Heat Rejection**, **Inlet Temperature**, and **Inlet Pressure** can be provided as a *constant*, *polynomial* or *piecewise-linear* profile that is a function of time. If *user-defined-enthalpy* is selected as the **Auxiliary Fluid Properties Method**, you will need to specify the **Inlet Quality** and the **Pressure Drop**. More information is available in Specifying the Auxiliary Fluid Properties and Conditions (p. 868).

k. Click **Apply** in the **Ungrouped Macro Heat Exchanger** dialog box to save all the settings. Once you click the **Apply** button, the NTU matrix will be computed from the raw data. Therefore, make sure you click **Apply** at the very end of your setup.

---

**Important**

When you click **Apply**, look for any error or warning message in the ANSYS Fluent console. Some of the common errors you may see displayed are due to the NTU computations not converging. In such cases, check that
• you have entered the data correctly
• the values of the data are reasonable
• the operating condition for the auxiliary fluid flow rate is not too far from the range of the heat transfer data

Other error messages you may encounter may be due to macros not getting any cells assigned to it. In such cases, make sure that
• the heat exchanger core is rectangular
• the directions are correct
• you are using uniformly spaced cells in both directions
• the mesh is either a hexahedra or wedge and is structured

I. Repeat steps (a)–(k) for any other heat exchanger fluid zones.

To use multiple fluid zones to define a single heat exchanger, or to connect the auxiliary fluid flow path among multiple heat exchangers, see Using the Grouped Macro Heat Exchanger Model (p. 871).

For additional information, see the following sections:
- 14.3.2.1. Selecting the Zone for the Heat Exchanger
- 14.3.2.2. Specifying Heat Exchanger Performance Data
- 14.3.2.3. Specifying the Auxiliary Fluid Inlet and Pass-to-Pass Directions
- 14.3.2.4. Defining the Macros
- 14.3.2.5. Specifying the Auxiliary Fluid Properties and Conditions
- 14.3.2.6. Setting the Pressure-Drop Parameters and Effectiveness

14.3.2.1. Selecting the Zone for the Heat Exchanger

Choose the fluid zone for which you want to define a heat exchanger in the Fluid Zone drop-down list.

14.3.2.2. Specifying Heat Exchanger Performance Data

Based on the heat transfer model you choose in the Model Data tab, some performance data must be entered for the heat exchanger.

- **ntu-model**: For the ntu-model you will provide the heat transfer for different primary and auxiliary fluid flow rates. Click the Heat Transfer Data... button to open up a tabular dialog box. Set the number of auxiliary flow rates and primary fluid flow rates. The dialog box will resize itself accordingly. You will need to provide various primary fluid flow rates and auxiliary fluid flow rates and the corresponding heat transfer values. You may write this data to a file that can be read later.

- **simple-effectiveness-model**: For this model, you will need to provide velocity versus effectiveness data. To provide this you can click the Velocity Effectiveness Curve... button. This will open up a tabular dialog box. In this dialog box, you can set the number of points in the curve, then you can provide velocities and corresponding effectiveness values. This data can be written to a file and read back.
14.3.2.3. Specifying the Auxiliary Fluid Inlet and Pass-to-Pass Directions

To define the auxiliary fluid direction and flow path, you will specify direction vectors for the Auxiliary Fluid Inlet Direction and the Pass-to-Pass Direction in the Geometry tab. Figure 14.17: 1x4x3 Macros (p. 867) shows these directions relative to the macros.

For some problems in which the principal axes of the heat exchanger core are not aligned with the coordinate axes of the domain, you may not know the auxiliary fluid inlet and pass-to-pass direction vectors a priori. In such cases, you can use the plane tool as follows to help you to determine these direction vectors.

1. “Snap” the plane tool onto the boundary of the heat exchanger core. (Follow the instructions in Initializing the Plane Tool (p. 1591) for initializing the tool to a position on an existing surface.)

2. Translate and rotate the axes of the tool appropriately until they are aligned with the principal directions of the heat exchanger core. The depth direction is determined by the red axis, the height direction by the green axis, and the width direction by the blue axis.

3. Once the axes are aligned, click the Update from Plane Tool button in the Ungrouped Macro Heat Exchanger dialog box. The directional vectors will be set automatically. (Note that the Update from Plane Tool button will also set the height, width, and depth of the heat exchanger core.)

14.3.2.4. Defining the Macros

As discussed in The Macro Heat Exchanger Models (p. 858), the fluid zone representing the heat exchanger core is split into macros. Macros are constructed based on the specified number of passes, the number of macro rows per pass, the number of macro columns per pass, and the corresponding auxiliary fluid inlet and pass-to-pass directions (see Figure 14.17: 1x4x3 Macros (p. 867)). Macros are numbered from 0 to \((n - 1)\) in the direction of auxiliary fluid flow, where \(n\) is the number of macros.
